Printed by W. & R. Chambers, Limited.

EDITORIAL NOTE.

The first volume of the new edition of CHAMBERS'S ENCYCLOPÆDIA was issued in March 1888; the work is now completed within less than five years by the issue of the tenth volume. It is not merely, as was promised, a thoroughly new edition, but is to all intents and purposes a new work; and the publishers and editor are confident that, whether regard be had to fullness, compactness, accuracy, proportion, systematic arrangement, or literary form, it greatly surpasses the former edition, and is the best book of its scope and kind extant. Nearly a thousand authors—many of them of the first eminence, and all specially qualified for their work—have contributed; and to them the reader is indebted for the authority, variety, interest, and readableness of the articles. He need but glance at the lists of principal articles prefixed to the successive volumes to realise how numerous and how eminent those contributors have been.

An encyclopædia is by no means, as has been frequently assumed ever since the name or the thing was known, a dry and formless catalogue of disjointed or chaotic facts, whose sole claim to existence lies in its being handy for reference and moderately correct. On the contrary, a well arranged encyclopædia is a microcosm, a conspectus of the universe, a more or less effective view of 'the proficience and advancement of learning divine and human,' to use Bacon's ambitious phrase. It is a stocktaking in almost every department of science; and should be even less remarkable for its multifariousness and fullness than for the proportion, interdependence, and due subordination of parts.

This systematic form, for which the editorial staff must mainly be held responsible, the editor believes he has in great measure secured; and he is glad heartily to thank his colleagues one and all for their unremitting, laborious, conscientious, and scholarly co-operation. Mr Francis Hindes Groome and Mr Thomas Davidson have from the outset had a share in almost every department of the editorial duties, besides contributing many and important articles from their own pens. The Rev. William Dundas Walker has throughout done admirable work both in writing and revising articles—as did also Mr John T. Bealby for a shorter period. Mr Robert Cochrane has rendered invaluable service in the secretarial and other departments. At the commencement help which has been of lasting value was given by Mr William Inglis, a partner in the Firm, who died before the first volume was issued. His work has been continued by his successor, Mr Robert Mowat, who has read the proofs and made many useful suggestions. The Rev. James Inglis has sustained the labour of preparing the Index; and the illustration of all the ten volumes—often from photographs by Messrs Frith and Mr Gambier Bolton—has been under the charge of Mr J. R. Pairman. Some of the outside contributors have, in respect of the continuity of their work, been practically on the staff; thus Mr J. Arthur Thomson has written almost all the articles on zoological subjects. Mr W. S. Washburn, of Messrs J. B. Lippincott Co., Philadelphia, has been very helpful in regard to the American articles. An editor's chief work is to edit; but besides revising all the articles, the editor has been one of his own most frequent contributors—mainly in the shorter articles and such as fell within his special competency.

Over and above correction by authors and by the printer's readers, every article has been read in proof by him and at least two of his colleagues. In many cases moreover articles in proof have been submitted to specialists other than the writers; their courteous help has been already acknowledged in the lists of principal articles. A large number of the articles on towns and institutions have been most kindly revised by town-clerks or other officials.

Of those who projected and carried through the first edition (1859–68)—into whose labours we of the present edition have entered—the great majority are no longer with us. Dr William Chambers and Dr Robert Chambers had passed away before this edition was undertaken by the Firm, then headed by Mr Robert Chambers the Second, who, dying in 1888, left as representative of the old house his son Mr C. E. S. Chambers. Dr Findlater, the first editor, had died in 1885; but of the hundred contributors to the first edition nearly twenty have also contributed to the second—of whom, alas! five have died during the publication of these volumes. Of other collaborateurs on this edition we have lost by death no less than ten since the work began.

Now that the days of the polyhistors are past, not merely the general reader but even the man of special learning may often find his account in referring to what is a compendium of many libraries; the most accomplished specialist in one department may find it useful to read the articles by brother specialists in other departments. But encyclopædists make no claim to omniscience or infallibility; and none can be so conscious as the editor of the inevitable shortcomings of a work treating '*de omni re scibili et quibusdam aliis*' and yet strictly limited to ten volumes not much larger than in the former edition. The necessity of keeping within the prescribed limits has been both a painful and laborious condition of the editor's work, and must be the apology for compression within short space of many articles well worthy to extend to much greater length. Still, from the very nature of the case, the encyclopædia can be only a guide, a preparation, a stepping-stone, a stimulus to further and fuller study elsewhere. The spirit was good in which Bartholomæus Anglicus concluded his *De Proprietatibus Rerum*, the 'Encyclopædia of the Middle Ages,' with words thus Englished by his translator:

> '*I make protestation in the end of this worke, as I did in the beginning, that in all*
> '*that is in divers matters conteined in this worke, right little or naught have I set of mine*
> '*owne, but I have followed veritie and truth, and also followed the wordes, meaning, and*
> '*sences, and comments of holy Saints and of Philosophers; that the simple that may not*
> '*for endlesse many bookes seeke and find all the properties of thinges . . . may heere find*
> '*somewhat that he desireth. And that I have taken is simple and rude; but I think them*
> '*good and profitable for me . . . and to other such as I am. Therefore I counsayle the*
> '*simple that they dispise not nor scorne this simple and rude worke; when that they have*
> '*perfect understanding and knowledge of this . . . then to understande and to have*
> '*knowledge of greater, higher, and more subtill things. I counsell that they leave not to*
> '*seeke and search the learning and doctrine of greater authors and doctors. And that I*
> '*doe and leave on their owne avisement and wit if they will correct and amend that that*
> '*is insufficientlie said, and then expediently to adde and put more thereto, as God giveth*
> '*them grace and science. . . .*'

DAVID PATRICK.

Edinburgh, 17*th December*, 1892.

Among the more important articles in this Volume are the following:

Sweating System	D. F. Schloss.
Sweden	J. T. Bealby.
Swedenborg	James Speirs.
Swift	Professor Stanley Lane-Poole.
Swimming	C. J. Butcher.
Swinburne	Walter Whyte.
Switzerland	Carus D. Cunningham.
Sydney	John Plummer.
Symbiosis; Zoology	Professor J. Arthur Thomson.
Tacitus	Dr J. P. Steele.
Tactics, Military	Lieut.-Col. Dunlop, R.A.
Tactics, Naval	Captain Garbett, R.N.
Tai-Pings	Professor Legge.
Talleyrand; Thiers	William Wallace, LL.D.
Talmud; Targum	Emmanuel Deutsch & Rev. J. Milne.
Tasmania	Sir E. N. C. Braddon, K.C.M.G., &c.
Tasso	Signora Cantagalli.
Taste	Professor Haycraft.
Tax	Thomas Raleigh.
Taylor, Jeremy	Thomas Davidson.
Tea	R. C. Haldane.
Technical Education	Principal Grant Ogilvie.
Teeth, Diseases of	John Girdwood.
Telegraph	Sir W. H. Preece, K.C.B., F.R.S.
Telephone; Telescope	Dr Alfred Daniell.
Temperance	Sir Wilfrid Lawson, Bart.
Temple	Rev. J. Sutherland Black.
Tennis	J. Norman Heathcote.
Tennyson	Professor Palgrave.
Terrier	George G. Tod.
Tertullian	Rev. A. P. Davidson.
Tetanus	Dr R. A. Lundie.
Thackeray	Richmond Thackeray Ritchie.
Theatre	Robert W. Lowe.
Theocritus	John Masson.
Theosophy	Mrs Annie Besant.
Thermodynamics	Professor Knott.
Thomson, James	Francis Watt.
Thoreau	John Burroughs.
Thucydides; Troy	F. B. Jevons.
Tibet	George Barclay.
Tides	Professor Knott.
Timber; Tin; Zinc	A. Galletly.
Tithe	R. E. Prothero.
Titian	P. G. Hamerton.
Tobacco	A. Wingham.
Toronto	Martin J. Griffin.
Torpedo	Captain Gladstone, R.N.
Traction-Engines	Professor T. H. Beare.
Trade-Marks	A. W. Renton.
Trade Unions	George Howell, M.P.
Tramways	E. R. M'Dermott.
Transubstantiation	Rev. W. L. Gildea, D.D.
Transvaal; Zulus	E. P. Mathers.
Trent, Council of	T. G. Law.
Triassic; Volcanoes	Professor James Geikie.
Trollope	T. Adolphus Trollope.
Trotting	John Gilmer Speed.
Trout	Archibald Young.
Tubercle	Dr R. W. Philip.
Tunis	John Gunn.
Turgot	Thomas Kirkup.
Turkestan	Arminius Vambéry.
Turkey	Professor Stanley Lane-Poole.
Turner, J. M. W.	P. G. Hamerton.
Types	John Southward.
Unitarians	Rev. R. B. Drummond.
United States—	
Geography	Professor Frank B. Greene.
Geology	Professor N. S. Shaler.
Education	Richard G. Boone.
History	Professor Edward Channing.
Literature	Professor Robert Ellis Thompson.
Universities	P. Hume Brown, LL.D.
Vaccination	John B. Buist, M.D., F.R.C.P.
Vagrants	Chief-Constable Henderson.
Van Dyck	J. M. Gray.
Variation	Professor C. Lloyd Morgan, F.R.S.
Veda	Professor Eggeling.
Vega; Velazquez	John Ormsby.
Veget. Physiology	A. J. Herbertson.
Vegetarianism	Josiah Oldfield.
Venezuela; Uruguay	W. Dundas Walker.
Veterinary Medicine	Principal Williams.
Victoria	George Collins Levey, C.M.G.
Vine	William Thomson.
Violin	Colin Stalker.
Virgil	J. W. Mackail.
Voltaire	Francis Espinasse.
Volunteers	Lord Kingsburgh.
Wagner	Franklin Peterson, Mus.Bac.
Wales—History	Dr Alfred Daniell.
" Lang. and Lit.	Professor J. Morris Jones.
Walpole, Horace	Austin Dobson.
Washington City	A. R. Spofford.
Washington, George	Professor Edward Channing.
Waste Products	A. Galletly.
Water-Supply	Sir F. Bramwell, Bart., D.C.L.
Weaving	James Paton.
Weber	H. Whitehead.
Webster, Daniel	J. P. Lamberton.
Webster, John	Charles W. Boyd.
Weismann	Edward Clodd.
Wellington	Lieut.-Col. Dunlop, R.A.
Wesley	Rev. Hugh Price Hughes.
Western Australia	James Bonwick.
Westminster	Rev. W. J. Loftie.
Wheat	James MacDonald.
Whisky	J. A. Nettleton.
Whist	Henry Jones ('Cavendish').
Whitebait; Whiting	J. T. Cunningham.
Whitman; Whittier	H. B. Baildon.
Wight, Isleof; Wilts	F. N. Worth.
Wilkes, John	W. Fraser Rae.
Will	Professor Sorley.
William I. and II.	Rev. William Hunt.
William I. (Germany)	G. Barnett Smith.
Winchester	Rev. A. G. L'Estrange.
Wind	Alexander Buchan, LL.D.
Wine	John Angell, F.C.S., F.I.C.
Witchcraft	Thomas Davidson.
Wolf	W. E. Hoyle.
Women's Rights	Mrs Fawcett, LL.D.
Wood-Engraving	J. R. Pairman.
Wool	Professor Beaumont.
Wordsworth	Professor Palgrave.
Writing	Canon Isaac Taylor.
Wycliffe	F. D. Matthew.
Xenophon	H. A. Holden, LL.D.
Yacht	David Pollock.
Yellow Fever	Dr R. W. Felkin.
York; Yorkshire	Canon Isaac Taylor.
Zend; Zoroaster	Rev. R. L. H. Mills, D.D.
Zola	Professor Saintsbury.

The Publishers beg to tender their thanks, for revising articles, to the Dean of Worcester; the Agent-general for Western Australia; the town-clerks or other officials of Warrington, Warwick, West Bromwich, Whitby, Workington, Yarmouth; to Professor Zahn of Erlangen, for revising 'Tatian;' and to Mr D. L. Miller, for the materials of 'Tunkers.'

The following Articles in this Volume are Copyrighted by J. B. Lippincott Company in the United States of America :

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Swastika. See SVASTIKA.

Swat, a river in Kafiristan (q.v.), joining the Kabul river near Peshawar. In 1897 the 'Mad Mullah,' proclaiming himself the successor by divine selection of the Akhund of Swat, who died in high reputation about 1878, roused the tribes inhabiting the Swat valley to a holy war against the infidels. They attacked the British camp at Malakand, but were repulsed. The disturbance, however, spread through the neighbouring tribes, including the Buners, Waziris, Urakzais, and Afridis, and resulted in the frontier war which terminated with the brilliant engagement at Dargai, 20th October 1897.

Swatow, a seaport of China which has been opened to foreign trade since 1869, stands at the mouth of the river Han, 225 miles E. of Canton, in the province of Kwang-tung. It is the seat of great sugar-refineries and bean-cake and grass-cloth manufactures. In 1897 its direct trade with foreign countries was valued at—imports, £1,573,550; exports, £553,700. The chief imports are beans, cotton, opium, rice, metals, &c. The chief exports are sugar, tobacco, grass-cloth, cloth and nankeen, tea, &c. Pop. (1897) 35,000.

Swaziland, a South African native state, lying on the west side of the Libomba Mountains, and forming an intrusion into the east of the Transvaal. It has an area of 8500 sq. m.; a pop. of 60,000 Swazis, a Zulu-Kaffir race, and (in 1899) about 800 white men; and a trade valued at £70,000 through Natal, exclusive of what goes by way of Delagoa Bay. The minerals of Swaziland are of great value, including gold and coal, and its agricultural and pastoral resources are considerable. The independence of this little state was recognised by its powerful neighbours, the South African Republic and the British government, in 1884; in 1890 the white settlers, mainly gold-miners, were put under joint 'government committee,' appointed by Britain and the Boers; since 1895 Swaziland is under the protection of the Republic, and its independence is now only nominal. In 1898, by a proclamation, the Transvaal laws were made applicable through Swaziland, except as to customs.

Swearing, or PROFANE SWEARING, the habit of using the name or attributes of God in a light and familiar manner by way of asseveration or emphasis. It was specially condemned by the Mosaic law, was long punished by severe penalties, and is still an actionable offence in England. By oaths are loosely understood also many terms and phrases of gross and obscene character. There is a legitimate use for solemn cursing; but weak men of limited vocabulary, under the pressure of excitement, seek for artificial strength or verification by employing irrelevant words that carry with them ideas of gravity or strength. Seafaring men and persons in command generally often use such expressions to add weight to their words, and some apology may be found for them in the fact that the persons with whom they have usually to deal have been so accustomed to their use as not to be readily inclined to obedience without them. Again, other and more imaginative men from the days of Rabelais until now garnish their talk with oaths as a mere exercise of verbal ingenuity, or by way of set-off to their conversation.—'How now?' said Ponocrates; 'you swear, Friar John.' 'It is only,' said the monk, 'but to grace and adorn my speech; they are colours of a Ciceronian rhetoric.'

To call God to witness is a thing natural enough on occasions of grave asseveration, as in giving witness in courts of law and the like, and it has been from the beginning a custom to take oaths on things sacred or august, as the head of the emperor, the beard of the Prophet, the sword blade or hilt, and the gospels. Thomas Becket denounced John the Marshal of England for swearing on the *troparium*, a collection of versicles and sequences used in the service of the mass. We find oaths frequent enough among the Greeks and

Romans: Pythagoras is said to have sworn by the number four; Zeno, by the caper; Socrates used mild oaths, as 'By the dog,' and Aristophanes tells of a time when no men swore by the gods, but all by birds. The Romans used 'Mehercule,' 'Medius Fidius,' 'Edepol,' 'Ecastor,' and 'Mecastor' (properly a woman's oath), &c. Brantôme tells us Louis XI. said 'Par la Pâque Dieu;' the oath of Francis I. was characteristic—'Foi de gentilhomme.' 'Ventre Saint-Gris,' again, was one of the Gascon oaths of Henry IV. of France, which he alternated with another favourite, 'Jarnidieu.' Many of the modern French oaths, as 'Parbleu' (*par Dieu*), 'Corbleu' (*corps de Dieu*), 'Ventrebleu,' and 'Sacrebleu,' are illustrations of a process of softening an oath by a deliberate disguise, like the old-fashioned 'Gad' and 'Egad,' the north country 'Dod' and ''Scush' (*God's curse*), and the older English ''Slight' (*God's light*), 'Od's fish'—the usual oath of Charles II., 'Zounds' (*God's wounds*), 'Od's bodikins,' and the American 'Darn.' Similarly in Italy, between the severe laws against profanity and blasphemy and the necessity of confession, forms like 'Per Dio' became in early times disguised as 'Per Dinci.' Indeed the Italians, especially in Tuscany, are extraordinarily rich in oaths, many strange and grotesque forms being in use, and the meanings of common forms being carefully differentiated. Mr Story tells us that 'Dio mio' is proper as an expression of sudden surprise, 'Madonna mia' of pity and sorrow, 'Per Christo' of hatred and revenge. Nothing on the Continent strikes an English ear more strangely than the familiar use of 'Dieu' in France and of such phrases as 'Herr Je' in Germany, and English reticence refuses to accept the over-subtle apology even of a Cardinal Newman (*Lect. on Certain Diffic.* ix.), that this variety and fertility in adjurations and invocations is merely because a Catholic populace has a greater insight into the unseen world than a Protestant. 'The Catholic's very jesting, and his very oaths, have been overruled,' says he, 'to create in him a habit of faith, girding round and protecting the supernatural principle.' But it is proper to explain that what James Howell calls 'this infandous custom of swearing' is to Continentals specially an English characteristic. Indeed Howell himself, after enumerating the performances of the German, the Italian, the Frenchman, the Spaniard, the Welshman, the Irishman, and the Scot, admits that 'for variety of oaths the English Roarers put down all.' Byron describes how Don Juan on his first arrival in England is rudely awakened from the innocent belief that 'their shibboleth "God damn"' is a usual salutation. Beaumarchais (*Le Mariage de Figaro*, iii. 5) says, 'Avec Goddam en Angleterre on ne manque de rien nulle part. . . . les Anglais à la vérité ajoutent par-ci par-là quelques autres mots en conversant; mais il est bien aisé de voir que Goddam est le fond de la langue.' We hear this phrase as a synonym for Englishman even from the pure lips of Joan of Arc, and we certainly find the oath in the other Elizabethan dramatists, and in Shakespeare, but not in anything like its modern pre-eminence of importance. Still we find oaths enough of all shades of profanity in early English literature, and corresponding denunciations in the writings of preachers like Jeremy Taylor and Thomas Fuller, down to the days of that genial but true moralist, the *Spectator*. A few of the more common old English oaths—all in Shakespeare—were 'Bodikins,' 'By Cock and Pie' (*God* and the Romish service-book), 'Cock's passion,' 'By 'r Lady,' 'Marry' (the Virgin *Mary*), 'By my halidom' (*holiness*), 'Od's me,' ''Sblood,' 'Gramercy,' 'By the rood' (the *Cross*), ''Shrew me.' Sir Thopas in the *Canterbury Tales* uses 'By ale and bread,' the dainty Madame Eglantine's greatest oath is only 'By St Eloy.' 'By Jove' and 'By George' are still heard; 'the dickens' (*devil*) already occurs in the *Merry Wives;* 'the deuce' is at least of the 17th century, although hardly Middle English, *pace* Professor Skeat; 'By the living Jingo' has been boldly described as Basque, and was rendered classic by the *Vicar of Wakefield;* Etheredge and Dryden write 'bloody drunk;' Swift, 'bloody cold' and 'bloody sick'—early examples of one of the most odious of modern vulgarisms; the Duke of Wellington's 'twopenny damn' (of which there is an attempted innocent explanation) almost died with him; Queen Elizabeth, James I., Lord Thurlow, Picton, and Lord Melbourne, all notorious swearers, were catholic in their choice of oaths. The prophecy of Bob Acres (*Rivals*, ii. 1), that 'damns have had their day,' has not yet entirely come true, although the reformation of manners has long since driven swearing from the quarter-deck, and a Squire Western is now more than a phenomenon. Swift's *Swearer's Bank* (Scott's *Swift*, vol. vii.) is a characteristic satire on the profanity of his day. It is computed by geographers, he begins, that there are two millions in this kingdom [Ireland], of which number there may be said to be a million of swearing souls. It is thought that there may be 5000 gentlemen, each with one oath a day at a shilling each, yielding an annual revenue of £91,250. All classes of citizens contribute to this revenue, the farmers, the commonality, the hundred pretty fellows in Dublin alone at fifty oaths a head daily, the oaths of a little Connaught fair themselves computed at 3000. Militia under arms are to be exempted, nor is any advantage to be taken of any man's swearing in the Four Courts, provided he is at hearing in the exchequer or has just paid an attorney's bill. As for its medicinal use to help the lungs to throw off any distilling humour, on certificate of a course of swearing granted by any physician a permit may be issued to the patient, but all other licenses, compositions, or indulgences whatever are prohibited.

The church ever denounced profane swearing, but was powerless to check the practice. St Chrysostom spent twenty homilies upon it, and St Augustine's judgment is summed up with unnecessary severity in the solemn passage, 'Non minus peccant qui blasphemant Christum regnantem in cœlis quam qui crucifixerunt ambulantem in terris.' For much of our popular swearing is little more than the mere habit of vocabulary, a sin only from the lips outward, as Bishop Lightfoot said of the habitual profanity of the colliers of his diocese. Again, where swearing is a professional custom it is scarce possible to exist without conforming, and after all words have in themselves no absolute but a relative meaning. 'Our armies swore terribly in Flanders' in my Uncle Toby's time, nor was the practice extinct till long after the great French wars. And have we not still our familiar proverb 'to swear like a trooper.' But swearing has disappeared from the parade-ground, though it still lingers in the barrack-room. 'To swear like a bargee,' however, is a proverb still justifiable by the facts—an atmosphere of oaths continues to hang heavy over our canals and rivers. We are told that Robert Burton at last could only be made to laugh by going down to the Bridgefoot in Oxford and hearing the bargemen scold and storm and swear.

The old forms of excommunication in ecclesiastical use supplied forms enough, and the specimen of the powers of Ernulphus given in *Tristram Shandy* certainly displays 'an orientality we cannot rise up to, a copiousness of invention, a possession of all the excellencies of a swearer

which make it impossible to swear out of it.' The advantage of a theological vocabulary is seen further in Scott's story of the swearing-bout between a skipper and a broken-down minister, where the latter swore his antagonist dumb with a copiousness and variety he could not equal. In England the growth of Puritanism was marked by a series of attempts to stamp out swearing. In 1601 a measure for this end was introduced into the House of Commons, and one was carried in 1623. 'Not a man swears but pays his twelve pence,' says Cromwell proudly of his Ironsides. As early as 1606 swearing in plays had been forbidden, and even Ben Jonson himself narrowly escaped the £10 penalty. An act of 1645 in Scotland details the penalties to be inflicted, even on ministers of religion—it will be remembered that Barham recommends these not to go beyond 'zooks.' Shirley's play, *The Young Admiral* (1633), is especially noted as 'free from oaths, profaneness, and obsceneness.' When Davenant's *Wits* next year was presented to Sir Henry Herbert for license, the latter crossed out many expressions. Davenant appealed to the king, who directed the Master of the Revels to allow such words as 'Faith,' 'Death,' and ''Slight.' Sir Henry made the following entry in his office-book: 'The king is pleased to take "Faith," "Death," and "'Slight" for asseverations and no oaths, to which I do humbly submit as my master's judgment; but under favour conceive them to be oaths, and enter them here to declare my opinion and submission.' St Paul's Cathedral is supposed to have been built without an oath, the regulations of Sir Christopher Wren being so stringent, and this may be allowed to remain its most remarkable distinction.

Profane swearing, according to the law of England, is an offence for which the party may be convicted under an act of George II. by a justice of the peace according to a scale of penalties. A day labourer, common soldier, sailor, or seaman forfeits 1s. per oath; every other person under the degree of a gentleman, 2s.; and every person above the degree of a gentleman, 5s.; for a second offence, double these sums; for a third, treble, &c. If the cursing take place in presence of a justice of the peace, the latter may convict the swearer then and there, without further process or evidence; and in all cases a constable may apprehend a profane swearer, and carry him before a justice. On one occasion a man swore a volley of oaths, twenty times repeating the oath, and the justices fined him 2s. for each repetition, making in all £2, and this was held a proper conviction. It seems that this act does not apply to women; but there are provisions of a more general character in several modern police acts which impose a penalty for using profane or obscene language in public places. The justices of the peace in Scotland have a similar jurisdiction, to convict of profane swearing, and fine according to the rank of the party.

See articles on Blasphemy and Oath; also Julian Sharman, *A Cursory History of Swearing* (1884).

Sweat (A.S. *swát*), the moisture exuded by the skin, in which about 2 per cent. of solid matters is present, consisting of salt; formic, acetic, butyric, and other fatty acids; neutral fats; and cholesterin. The manner of its excretion, its uses, &c. are considered at Skin (q.v.).

Sweating Sickness, an extremely fatal epidemical disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name 'because it did most stand in sweating from the beginning until the endyng,' and, 'because it first beganne in Englande, it was named in other countries the Englishe sweat.' It first appeared in London in September 1485, shortly after the entry of Henry VII. with the army which had won the battle of Bosworth Field on August 22. It was a violent inflammatory fever which, after a short rigor, prostrated the powers as with a blow, and, amidst painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fetid perspiration. All this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerable, yet every refrigerant was certain death. 'Scarce one amongst a hundred that sickened did escape with life' (Holinshed)—a statement which, while probably greatly exaggerated, illustrates the dread with which the malady came to be regarded. Two lord mayors of London and four aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st of September to the end of October, during which short period 'many thousands' died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by a violent tempest on New-year's Day. In the summer of 1508 it reappeared in London, and in July 1517 it again broke out in London in a most virulent form, carrying off some of those who were seized by it within four hours. It seems chiefly to have attacked those in the upper classes or in comfortable circumstances. In many towns a third or even a half of the inhabitants are said to have been swept away, again probably an overstatement. On this occasion the epidemic lasted about four months. In May 1528—the year in which the French army before Naples was destroyed by pestilence, and in which the putrid fever known as *Trousse-galant* decimated the youth in France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, 'and fourteen months later brought a scene of horror upon all the nations of northern Europe, scarcely equalled in any other epidemic.' How many lives were lost in this epidemic, which has been called by some historians *the great mortality*, is unknown; the fact that King Henry VIII. left London, and endeavoured to avoid the disease by continually travelling, shows the general feeling of alarm that existed. We hear of it at Calais in the same year, but nowhere else out of England. In the following summer, having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lübeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, &c. In September it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia; but after three months it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (March or April 1551) it burst forth in Shrewsbury, spread rapidly over the whole of England, but disappeared by the end of September. The deaths were so numerous that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year that the sweating sickness uniformly spared foreigners in England, and on the other hand followed the English into foreign countries. The immoderate use of beer amongst the English was considered by many as the principal reason why the sweating sickness was confined to them. Since 1551 the disease has never appeared as it did then and at earlier periods. Its nearest ally is Sudamina (q.v.), or miliary eruption, which has appeared in frequent, but usually limited, epidemics in France, Italy, and Germany (still called

there 'the English sweat'), during the 18th and 19th centuries, sometimes, as in the dept. of Vienna in 1887, in so severe and even fatal a form as to suggest the older epidemic in miniature.

See Dr John Caius, *A Boke against the Sweatyng Sicknesse* (1552); Hecker, *Epidemics of the Middle Ages* (Syd. Soc. Trans.); Hirsch, *Geographical and Historical Pathology* (New Syd. Soc. Trans., vol. i. p. 82); and Creighton, *History of Epidemics in Britain* (1891).

Sweating System. This subject was first brought prominently before the public in 1847–48 by the *Morning Chronicle* newspaper, and subsequently by a pamphlet (*Cheap Clothes and Nasty*) and a novel (*Alton Locke*), both from the pen of Charles Kingsley. It was shown that some of the journeymen tailors, instead of doing the work on the premises of their masters, had commenced the practice of taking the garments to their own houses, where they called in the assistance of their families and of other persons. This system was called 'the Sweating (i.e. over-working) System,' because the persons employed under it worked harder than the public opinion of the men in the tailoring trade considered reasonable; just as an unconscionably industrious schoolboy is reproached by his fellows for 'swatting.' The term, 'the sweating system,' soon began to be applied to more or less analogous practices in other trades, and generally to all practices objected to by the workers. 'Sweating' is now used to denote unfair treatment of any kind, without reference to any particular system of employment. But the sweating system is still chiefly applied to cases in which work is sub-contracted—i.e. in which a principal employer, instead of having the work done by men in his own employment, hands it over to a 'middleman,' who gets it done with the assistance of persons engaged by him for the purpose. In some cases the sub-contractor and his employees work on the premises of the principal employer, this type of middleman being usually called a 'piece-master.' But, as a rule, when the sweating system is spoken of reference is made to the 'sweating-master' or 'garret-master,' who employs his workpeople in his own 'sweating-den.' In February 1888 a select committee of the House of Lords was appointed to examine into the sweating system in East London, the reference being afterwards extended to cover the United Kingdom. The industries investigated included the tailoring trade, shirt-making, mantle-making, furriery, boot-making, cabinet-making and upholstery, chain and nail making, the cutlery and hardware trades, and also dock labour and government contracts. The final Report of this committee, published in April 1890, states that 'the earnings of the lowest class of workers are barely sufficient to sustain existence. The hours of labour are such as to make the lives of the workers periods of almost ceaseless toil, hard and often unhealthy. The sanitary conditions under which the work is conducted are not only injurious to the health of the persons employed, but are dangerous to the public, especially in the case of the trades concerned in making clothes, as infectious diseases are spread by the sale of garments made in rooms inhabited by persons suffering from smallpox and other diseases. . . . As a rule, however, it must be remembered that the observations made in respect to sweating apply, in the main, to unskilled or only partially skilled workers, as the thoroughly skilled workers can almost always obtain adequate wages.' While blaming employers as 'regardless of the moral obligations which attach to capital when they take contracts to supply articles and know nothing of the condition of the workers by whom such articles are made, leaving to a sub-contractor the duty of selecting the workers,' the committee declare that 'the middleman is the consequence, not the cause of the evil; the instrument, not the hand which gives motion to the instrument, which does the mischief. Moreover, the middleman is found to be absent in many cases in which the evils complained of abound.'

On the other hand, the middleman or sub-contractor is certainly present in very numerous instances in which the evils of sweating are absent. Thus, in the cotton trade, the 'minders' employ their own 'piecers;' in the iron trade a great number of operations are entrusted to sub-contractors ('puddlers' employing their own 'underhands,' 'hammermen' employing their own assistants, &c.); sub-contract is widely prevalent in mines and quarries, in the ship-building and in numerous other industries, but is in these cases unaccompanied by serious oppression of the workers, and is not called the sweating system. The sub-contractor usually himself performs a part, generally the most difficult part, of the work, and in all cases renders useful services by organising and directing the labour of his subordinates; while the remuneration which he receives is, as a rule, by no means out of proportion to the importance of the duties which he fulfils. But, since the amount of his remuneration depends directly upon his getting his employees to do a *maximum* of work for a *minimum* of pay, the sub-contractor, especially if his workpeople are deficient in skill or incompetent to combine against oppression, tends to become a greedy and exacting task-master.

Before the final Report of the Lords' Committee was issued the sweating system had been abolished in the metropolitan docks and in the greater part of the London boot trade by successful strikes. Since its publication most of the principal legislative provisions recommended in this report have been made. See the Factory and Workshop Act, 1891, and the Public Health (London) Act, 1891. The duty of the nation to secure that those who do its work shall be fairly treated has been formally recognised by parliament, and is carried out by the government, which not only interferes to obtain for the workpeople employed by its contractors the full current rate of wages, but has in a recent important contract provided that the contractor, unless expressly authorised, shall not either sub-contract the work 'or employ any taskmen'—i.e. piece-master foremen. Many public bodies (including the London County Council and the municipal authorities of Birmingham, Gloucester, Leeds, Leicester, Liverpool, Manchester, Middlesborough, Nottingham, Salford, Sheffield, Sunderland, and West Ham) now require their contractors to pay full current wages; and in numerous cases contractors engaged on public works are prevented from sub-contracting, except so far as sub-contract is usual and necessary.

Further details in respect to the sweating system will be found in three Reports by Mr J. Burnett, Labour Correspondent of the Board of Trade: (*a*) on the Sweating System at the East End of London; (*b*) on the Sweating System in Leeds; and (*c*) on the Nail Makers and Small Chain Makers in South Staffordshire and East Worcestershire (1887, 331; 1888, c. 5513; 1888, 385, Eyre & Spottiswoode); the five Reports, Minutes of Evidence, Appendices, and Index of the Lords' Committee on the Sweating System; Booth, *Labour and Life of the People* (especially vol. i.); and *Methods of Industrial Remuneration*, by the present writer, David Schloss. See also the article IMMIGRATION.

Sweden (*Sverige*), a kingdom of northern Europe, occupying the eastern side of the Scandinavian peninsula. The Skager Rack and the Cattegat touch its south-western shores. In the far north-east it is separated from (Russian)

Finland by the river Torneå and its affluent, the Muonio. Almost the whole of the eastern side is washed by the Gulf of Bothnia and the Baltic Sea; this last also beats against its short southern coast. The longest line, from north to south, measures little short of 1000 miles, the greatest breadth 300; the area is 170,644 sq. m.; the coast-line is about 1550 miles. Besides the skerry-islands (see below) Sweden owns Gothland (q.v.) and Œland (q.v.).

Physical Features.—The country may be generally described as a broad plain sloping south-eastwards from the Kjölen Mountains (see NORWAY) to the Baltic. The only mountainous districts adjoin Norway; the peaks sink in altitude from 7000 feet in the north to 3800 in 61° 30′ N. lat. Immediately south of this point a subsidiary chain strikes off to the south-east, and, threading the lake-region of central Sweden, swells out beyond into a tableland with a mean elevation of 850 feet and maximum of 1240 feet. Fully two-thirds of the entire surface lies lower than 800 feet, and one-third lower than 300 feet, above sea-level.

By far the greater portion of Sweden is built up of crystalline gneisses and granite of the Azoic era, and of limestones, sandstones, clay-slates, and other slates of the Lower Silurian epoch. The non-fossiliferous formations, which fill the western, northern, and large portions of the southern parts of the country, lie as a rule close to the surface or are actually exposed. The Silurian strata are spread out in broad thin sheets, regularly disposed, but broken by large islands of granite, gneiss, eruptive trap (diabase), porphyry, greenstone. The Triassic and Cretaceous systems have just touched the southern end of the country. During the Glacial epoch the whole of Sweden was covered with ice. Its melting accounts for extensive deposits of glacial sand, clay, and gravel, as well as for the gigantic boulders and erratic blocks with which several districts are plentifully strewn, and the long narrow ridges of smooth stones, called *åsar*, that cross the country for many miles in a south or south-easterly direction. The eastern or Bothnian coast, like the western coast of Norway, is gradually rising; whilst the coast of Scania, in the extreme south, tends on the whole to subside. The islands of the skerry-fence (*Skärgård*) are nearly all small in size, low, bare of vegetation, and polished by the sea.

The climate of Sweden is continental in the north, along the Norwegian frontier, and on the southern plateau; the regions that border on the sea are more maritime. Yet both summer and winter, in all parts alike, are liable to considerable fluctuations from year to year. The difference between the winter and summer temperatures is of course much greater in the continental parts; for instance, in the extreme north as much as 49° F., whereas at Lund in the south it does not, as a rule, exceed 30°. The lakes in the colder (continental) districts of the north are ice-bound for some 220 days in the year; in the south for only about 90 days. The rainfall is greatest on the coast of the Cattegat (30 inches yearly), and decreases from west to east, and from south to north, being only 16 inches yearly in Norrland. The south-east corner is, however, exceptionally dry (17 inches).

Sweden is separated politically and geographically into three great divisions—Norrland, Svealand, and Gothland.

Norrland in the north is a region of vast and lonely forests and short, rapid mountain-streams. These torrents, none of them 300 miles long, reach the Gulf of Bothnia along narrow parallel valleys running to the south-east; as they drop from level to level they form cascades and waterfalls, some of remarkable grandeur. Many of the valleys are filled for many miles with ribbon-like lakes, some of great size; whilst their slopes, and the ridges that lie between them, are clothed with dense forests of pine, fir, and birch, with wild berry bushes and similar low shrubs growing in between the trees and around the moss-carpeted blocks of granite and porphyry. Besides the Lapps with their reindeer herds, and the Swedish woodcutters and miners, the only denizens of these forest tracts are wild animals (reindeer, bears, wolves, lynxes, gluttons, foxes, lemmings), birds of prey (hawks, eagles, falcons, owls), hares, and game birds (ptarmigan, blackcock, heath-cock, hazel-grouse, snipe). The innumerable aquatic birds and the gnats of Lapland must not be forgotten. Numerous little seaports, where the lumber, floated down the streams, is cut up, and the iron ore from Gellivara and other mines is smelted, nestle at the mouths of the rivers. This division is very rich in mineral resources, but iron ore is almost the only one that is extracted. Norrland is crossed by the most northerly railway in Europe (see LULEÅ).

The central division of Svealand, or Sweden proper, is a region of big lakes, and contains most of the mines. Lakes occupy nearly 14,000 sq. m., or 8·2 per cent. of the total area; but in Svealand several of the largest, as Vener, Vetter, Hjelmar, Mälar, are grouped together. Lake Mälar bears on its bosom a vast number (1300) of islands, many of them beautifully wooded, with royal palaces or noblemen's castles gleaming through the trees. Its shores too are studded with prosperous towns, castles, palaces, and factories. These great sheets of water are connected together by rivers and navigable canals, and by the same means have communication with the Baltic on the one side and with the Cattegat on the other. In spite of the fact that several rivers pour their floods into these lakes, a process of slow desiccation is going on throughout the region. Indeed the waters of Lake Mälar are at so low an elevation that at certain seasons there is an inflow from the Baltic. There is a pretty large area of forest in central Sweden, especially around the reed-fringed lakes. The firs of these districts are highly prized for ships' masts. Svealand possesses almost inexhaustible stores of iron and copper, and in less quantities silver, manganese, nickel, zinc, cobalt, and others.

Gothland, the southern division, contains a much higher proportion of cultivated land than either Norrland or Svealand. Wide plains stretch from the lakes to the Cattegat, and these as well as the southern coast provinces are all under agriculture. The rivers are short; the most important is the Göta, which, after forming the picturesque Trollhätta Falls, pours the waters of Lake Vener into the Cattegat at Gothenburg. Iron occurs in certain districts: Mount Taberg, for instance, the culminating point of the plateau, near the southern end of Lake Vetter, is a solid mass of magnetic iron ore. In Scania some 10,000 tons of coal are extracted annually, and large quantities of turf are dug. Turf moors cover fully 9 per cent. of the area of the country.

Population.—Since the middle of the 18th century the population has increased at a steady, though not very rapid, rate. In 1750 it numbered 1,785,727; in 1800 it was 2,347,303; in 1850, 3,482,541. The figures for 1880 and 1890 are given in the subjoined table (with the areas). By nationality the people are all Swedes, except some 17,000 Finns, 6000 Lapps, and 18,000 foreigners. The greater part of the people live in rural districts, only 20 per cent. being counted as 'townsfolk.' In 1890 there were eight towns whose population exceeded 20,000—Stockholm (q.v.), Gothenburg (104,657), Malmö (48,504), Norrköping (32,826), Gefle (23,484), Upsala (21,511),

Karlscrona (20,613), Helsingborg (20,410), and eleven more exceeded 10,000. Between 23,500 and 50,700 persons emigrate every year, nine-tenths of them going to the United States.

The state religion is that of the Lutheran Church, ruled by twelve bishops, of whom the Bishop of Upsala ranks as primate. Except about 22,000 persons, all the population belong to the national church; but religious confession is perfectly free to every man. In the matter of education Sweden occupies an honourable position amongst the countries of Europe. Primary education is compulsory but free, and there is an excellent system of elementary schools. The illiteracy, taking the country over, is not more than ·27 per cent. Various grades of secondary education are provided in more than 100 schools. Besides normal schools, schools of navigation, and technical schools, there are military, naval, artillery, veterinary, mining, agricultural, and other academies. The highest branches are provided for by the Medical Institution of Stockholm (330 pupils) and by the universities of Upsala (1880 students) and Lund (810). The percentage of illegitimate births has gone on steadily increasing all through the 19th century, from 6·14 in 1801 to 10 per cent. in 1890. The asylums contain about 11,500 idiots and insane, 4800 deaf-mutes, and 3700 blind. In the year 1888 1,031,250 savings-banks investors owned a total of £14,405,342, or an average of £13, 19s. 4½d. each. About 5½ per cent. of the population are recipients of poor relief.

Occupations.—More than one-half of the population are dependent on agriculture and its associated callings. Ninety-nine per cent. of the farms are less than 240 acres in size, and 84½ per cent. of the total do not exceed 25 acres. Between 7 and 8 per cent. only of the entire area is under cultivation, though in addition 4 per cent. is laid down as meadows. The principal crops are potatoes, oats, rye (of which the ordinary bread of the peasantry is made), barley, and wheat, beets for sugar, and roots for fodder. Gardening and fruit cultivation are somewhat neglected. There is comparatively little poultry. Some attention is given to the breeding of cattle and sheep, and both classes of animal are exported. Butter, upon the preparation of which great pains and skill are now expended, forms one of the largest items of the national exports.

The mines give employment to 34,000 persons, of whom more than 29,000 are engaged in extracting iron, and smelting and working it. In 1889 the iron-mines, which numbered 517, produced an aggregate of 2,009,380 tons. In the same year 123 other mines yielded 20,800 tons of copper, 8650 tons of manganese, 5900 tons of zinc, 700 tons of nickel, 270 tons of cobalt, and 13,000 oz. of silver.

About 40 per cent. of the aggregate surface is forest, and of this again 60 per cent. is in Norrland. Four-fifths of the forest area is private property. Only one-twelfth of the timber cut every year in Sweden is sent abroad; the rest is used in the ironworks, and metallurgical and other industrial establishments. About one-half of the quantity exported goes to Great Britain, chiefly in the form of pit-props.

The industries of Sweden have grown very rapidly since the middle of the 19th century. Between 80,000 and 90,000 persons, of whom one-fourth are women, are employed in the various industrial callings; and the year's results average the grand total of £11,600,000. The most important branches are ironworks, foundries, and so forth (220 establishments yielding an annual value of £1,513,400), sugar-refineries (£1,432,000), cotton-spinning and weaving (£1,350,500), breweries (£688,000), tobacco-factories (£594,000), paper-mills (£505,600), clothing-factories (£500,000), match-factories, tanneries, papier-maché works, brickworks, distilleries, glass and porcelain works, chemical works, and woollen-yarn factories. The old domestic industries—the spinning and weaving of linen and cotton—still survive in Ångermanland (Vesternorrland) and Elfsborg.

The inhabitants of the skerry-islands and of the coast-lands are mostly fishermen. Herring and sprats are caught off the southern coast; salmon, eels, flounders, mackerel, haddock, and cod are taken off the east coast. The fisheries are worth nearly half a million sterling annually.

Sweden possesses a commercial marine of 1400 vessels of half a million tons burden. The foreign trade of the country averages annually £20,000,000 for imports and £17,000,000 for exports; the corresponding totals in 1870 were £7,500,000 and £5,000,000. The imports from Great Britain average £2,800,000, and the exports to the same country £8,000,000, the figures in 1891–95 being practically stationary. The most important articles of import are textiles (£5,739,800 in 1889), groceries (£3,331,600), minerals and metals (£2,731,000), machinery (£1,843,000), grain and flour (£1,628,000), hair, hides, horn, &c. (£1,207,500), and animals and animal foods (£880,000). Of the exports timber is by a long way the most important: in 1889 it was valued at £7,462,000. Next come minerals and metals, chiefly iron and steel (£2,442,400 in 1889); animal foods and animals (£2,270,326), more than one-half of the total for butter; grain and flour (£998,000), paper (£911,700), and textiles. Great Britain takes nearly half the minerals, nearly all the butter, and one-half of the grain and flour, and sends back coal (£906,000), iron, machinery, and textiles.

Government.—The executive power is vested in the hereditary king. He is advised by a council of ten members, who are responsible to the parliament. Seven of these preside one each over seven public departments (justice, foreign affairs, interior, finance, war, navy, and ecclesiastical affairs). The king shares the legislative power with the parliament (*riksdag*), though he possesses the right of initiative and of veto. There are two houses, which enjoy equal powers, but as a rule sit and vote separately. The members of the first house

(147) are elected by the provincial councils and the municipal councils of certain large towns, one for every 30,000 inhabitants; they sit for nine years, and receive no salary. The members of the second house (228) are returned, by direct or indirect ballot as the electors themselves determine, one for every rural district that has less than 40,000 inhabitants, two for every rural district whose population exceeds that number, and one for every 10,000 in the towns; they are paid £66 each for each session. Every elector is eligible to sit in the second house of parliament. The twenty-four provinces and the city of Stockholm are each administered by a governor and a provincial council. The communes (parishes and towns) enjoy a liberal measure of self-government through their own local councils.

Justice is administered in the towns by the municipal magistrates and in each rural district by a judge appointed by the king acting with seven to twelve (elected) local assessors, whose verdict, if unanimous, overturns the decision of the judge. Press offences alone are tried by jury. There are three courts of appeal, in Stockholm, Jönköping, and Kristianstad, besides the Royal Supreme Court of Stockholm, with sixteen judges appointed by the king.

The military forces include a standing army and a militia. The former consists of (1) men who are enlisted and remain with the colours two to six years, and (2) a class (*indelta*) who receive a free cottage and annual pay, but are under arms for only about one month in the year. The militia embraces all the males who are liable to conscription; they serve from their twenty-first to their thirty-third year, but are only called up for exercise for some three weeks in autumn. The militia of Gothland may not be employed out of that island. The regular army numbers about 40,000 men, the militia 400,000. In addition there are 17,000 men enrolled in free volunteer or rifle societies. The navy consists of seventeen armoured coast-defence ships, fourteen steam corvettes and gunboats, thirty-six torpedo-boats and other small vessels, with 25,000 men, including a large reserve.

Finance.—The national accounts were balanced at £6,200,000 in 1899; and in the same year the national debt, incurred almost wholly for railways, reached the aggregate of £18,000,000.

The weights and measures and the coinage are the same as those of Norway (q.v.).

See A. Hammar, *Historiskt, geografiskt, och statistiskt Lexicon öfver Sverige* (8 vols. 1859–70); Hojer, *Konungariket Sverige* (1875–83); *Statistiskt Tidskrift* (1890 and 1891). In English see W. W. Thomas, *Sweden and the Swedes* (1892), and books of travel by Du Chaillu and Vincent, quoted under NORWAY.

History.—The earliest inhabitants of Sweden were in all probability Lapps or kindred Finnish tribes. The ancestors of the modern Swedes seem to have crossed over to the southern parts of Sweden during the stone age, according to Montelius some time before 1500 B.C. They drove the aborigines before them into the forests of the north and settled in their lands. At the dawn of the historic period Sweden was occupied by two Teutonic races, the Goths in the extreme south (Gothland) and the Swedes (Svea) in the lake-region (Svealand). Their manners and customs were the same; they spoke dialects almost identical; and their kings, elected by the freemen of the tribes, recognised as their common supreme head the priest-king of the great temple of Wodan at Sigtuna on Lake Mälar (but at Upsala from the tenth year of the Christian era). These priest-kings ruled for more than one thousand years from the Christian era. The first dynasty was that of the Ynglings; the last king of which, Ingjald Illrede (died 623), perished amid efforts to reduce the minor kings to the position of vassal princes. The next dynasty, that of the Skjoldungs, was founded by Ivar Vidfadme (died 647), a mighty conqueror. The most memorable of his successors were the famous Viking kings Harald Hildetand (died 735), Ragnar Lodbrok (794), Björn Jernsida (804), and Olaf Skatkonung (1026). During this long period the Swedes were in the countries round the Baltic what the Danes and Norsemen were on the shores of the North Sea (see NORTHMEN). In the 9th century, however, Scania was conquered by the Danes; and, except for certain short periods, it remained Danish down to the 17th century. Christianity was first preached in Sweden by Ansgar (q.v.) in the 9th century. From the middle of the ensuing century, for fully two hundred years, the Swedes, who clung fanatically to their heathen faith, and the Goths, who, nominally at least, professed Christianity, were generally arrayed in hostile camps. And this in spite of the fact, or rather in great part because of the fact, that an arrangement was come to by which each race should alternately elect the supreme pontiff-king at Upsala. Nor did the enmity cease after the Swedes became converted to Christianity under St Erik (IX.), whose religious zeal spurred him on to conquer great part of Finland (1155–60), a country that remained an appanage of the Swedish crown for 650 years. For the next century the Goths and Swedes had separate kings; and the clergy turned the ceaseless strife that ensued to their own account. Earl Birger, a man of great ability and conqueror of the rest of Finland, was the real ruler of the country during the reign of Erik XI. (died 1250), the last prince of the Swedish dynasty, as well as during the reign of his own son Waldemar, who was elected—the first of the Folkung kings—to succeed Erik. From the accession of Waldemar the animosities of the Swedes and Goths began to subside, and they gradually melted into one nation.

In the meantime, however, a new source of internal discord had grown up: the incessant wars had fostered the growth of a strong and ambitious nobility, who, with their natural allies, the higher ecclesiastics, not only treated the peasantry with great oppression, and even cruelty, but often either warred upon their king or made him little better than a puppet in their hands. King Magnus I. (1279–90), after deposing and imprisoning his incapable brother Waldemar, governed vigorously, and on the whole justly; he promoted the interests of all classes of his subjects and taught them to respect the law. As his son Birger (1290–1319) was only eleven years of age when he was placed on the throne, the reins of government fell into the wise and able hands of Torkel Knutsson, who added considerably to the territory of Finland and at home simplified the laws. But at length the king, instigated thereto by his brothers, committed a judicial murder upon Knutsson, and began to act arbitrarily. The patriotic party rallied round Mats Ketilmundsson, who guided his country to prosperity through the remaining year or two of Birger's reign and down to his own death in the seventeenth year of the reign of Birger's nephew Magnus II. (1319–63). This sovereign suffered himself to be influenced by unworthy favourites, who involved him in profitless wars abroad and led him into odious tyranny at home. In the end his subjects deposed him and conferred the crown upon his nephew Albert of Mecklenburg (1363–97). But Albert was equally unfitted to govern the turbulent nobles of Sweden; he surrounded himself with German courtiers and soldiers, and in order to support them raised revenues by unjust means, till at length the men whose ambitions he slighted offered the crown (1389) to Margaret (q.v.) of

Denmark, wife of Haco of Norway. This caused strife again; but by the union of Calmar (1397) and the accession of Margaret's grandnephew Eric XIII. the crowns of the three Scandinavian kingdoms became united on one royal head.

During the greater part of the 13th and 14th centuries Sweden was torn by almost constant internal conflicts. Her kings were grasping of power, sometimes incapable, generally tyrannical, and often cruel. Her nobles and ecclesiastics were fierce, turbulent, and unrefined; her people ignorant and rude. Agriculture was much neglected; industry there was none; trade was monopolised by the Hanseatic merchants; literature, learning, and culture scarcely existed at all.

The Swedes' acquiescence in the union of Calmar was, however, little more than a matter of form. In their hearts all were hostile to it, and they could only be kept tolerably quiet so long as they were governed by native viceroys. Even them they frequently forced to take up arms against the Danes, and many bloody battles were fought; for the king of Denmark had a strong party amongst the Swedish nobles and higher ecclesiasties, whilst the people (peasantry) and certain of the nobles were enthusiastically national. The chief events of the long contest, which lasted until 1524, may be summarily related. In 1434 the peasants of Dalecarlia, the most patriotic and liberty-loving in the country, rose in revolt under a clever mine-owner, Engelbrechtsson. They were quieted by the appointment of Karl Knudson, a Swedish noble, as viceroy of Sweden, to govern in co-operation with Engelbrechtsson. On the death of King Erik's successor (Christopher), in 1448, Knudson was crowned king as Charles VIII. After reigning nine years he was driven out of the country by Christian I. of Denmark, assisted by Archbishop Bengtsson; but he returned in 1467 and reigned till his death in 1470. During the next thirty-three years Sweden was ruled, in an able and enlightened manner, by Knudson's nephew Sten Sture (q.v.). He was succeeded by his nephew Svante Sture (1503–12), and Svante by *his* son Sten Sture the Younger (1512–20). This ruler, as patriotic and able as his predecessors, was mortally wounded in battle with Christian II. of Denmark. That savage monarch, on 8th November 1520, for the purpose of striking terror into the hearts of the Swedish people, caused ninety-four persons, mostly of noble rank, to be massacred at Stockholm ('the Blood-bath'), and followed up this atrocity by doing to death throughout the country fully five hundred more of the influential among the national party. These deeds roused the Dalecarlians to action: putting themselves under the leadership of Gustavus (q.v.) Vasa, they drove the hated oppressors out of the country, crowned Gustavus king (1523), and tore (1524) to shreds the union of Calmar. The most momentous event in the reign of this the ablest prince who had yet ruled over the Swedes was the adoption of the Reformed doctrines, principally through the exertions of Olaus and Laurentius Petri (q.v.) and the deliberate policy of Gustavus, who in reforming the church took care that the clergy did not make themselves too powerful.

Gustavus so endeared himself to his subjects that they declared (1544) that the throne, instead of being elective as hitherto, should be hereditary in the House of Vasa. Accordingly on his death the crown was given to his son Eric XIV. (1560). In a reign of eight years this prince did many foolish things, and even some arbitrary and cruel acts; he was at length deposed by his brother John III. John, without openly breaking with the Protestant Church, warmly countenanced the Jesuits in their attempts to recover Sweden for the Roman see. His son Sigismund, who had been chosen king of Poland in 1587, and assumed the Swedish crown in 1592, pursued the same policy, but in a more undisguised and resolute manner. The Protestant party, however, rallying round Sigismund's uncle, made (1600) him King Charles IX. in his nephew's stead. Charles re-established the Lutheran creed, curtailed the privileges of the nobility, fostered mining, laid out seaports, and made the weight of his influence felt in Russia and Germany. His successor was his illustrious son Gustavus (q.v.) Adolphus (1611–32). After his heroic death at Lützen the crown passed to his daughter Christina (q.v.), though for some time the real ruler was the great Oxenstierna (q.v.). By the acquisition, through the treaty of Westphalia (1648), of the ecclesiastical domains of Bremen and Verden, and the greater part of Pomerania, Sweden became a member of the empire. Further, a war with Denmark brought to the Swedish crown certain of the Baltic islands and the three southern provinces of Sweden (Scania). But in 1654 Christina resigned the crown to her cousin Charles (X.), Palgrave of Zweibrücken. Having crushed his Polish rival of the House of Sigismund in a terrible battle near Warsaw (1656), this king finally expelled the Danes from the Swedish continent. The accession of his youthful son Charles XI. in 1660 was signalised by an agreement with the Polish branch, who not only abandoned their claim to the Swedish crown, but gave up Livonia and Esthonia. In the course of an ill-advised war against Denmark and Brandenburg combined the Swedes suffered several military disasters (notably at Fehrbellin in 1675). The king, concluding peace in 1679, set himself energetically to remove the causes of this national humiliation and weakness, and at his death (1697) left his country once more prosperous and powerful. But the ancient foes of Sweden —Denmark, Poland, and Russia—deeming the accession of the youthful Charles XII. (q.v.) a favourable opportunity to recover what they had lost, made common cause against him. As Charles left no heir the nobles conferred the crown upon his sister, Ulrica Eleonore (1718–20), but utilised the opportunity to wrest much of the royal prerogative from her. The new council of state which the nobility chose from their own order made peace with the enemies of Sweden by selling to them the provinces beyond sea, e.g. Bremen and Verden to Hanover, Hither Pomerania to Prussia, and Livonia, Esthonia, Ingermanland, and Karelia to Russia. Thus Sweden fell from the rank of a first-rate power which she had held for about a century. All through the reign of Ulrica and her consort, Frederick of Hesse (crowned king in 1720), as well as throughout the long reign of the weak-kneed Adolphus Frederick (1751–71), the kingdom was dominated by the nobles, who, however, were divided into two parties, the Caps, advocates of peace and opponents of royal absolutism, and the Hats, the war party, who were infected with French ideas. Gustavus III. (q.v.), shortly after his accession, abolished the council of state and restored the constitution that had been in force before Ulrica's accession. But neither he nor his son Gustavus IV. (q.v.), in spite of all they did for Sweden, can be called a wise and successful king.

The principal figure in the reign of the next sovereign, Charles XIII. (1809–18), was the French general Bernadotte, who was adopted as heir to the Swedish crown in 1810, and the principal event the acquisition of Norway (1814). Bernadotte succeeded as Charles XIV. (q.v.) in 1818, and in a reign of twenty-six years directed his energies to such schemes as the making of roads and canals, the cultivation of barren tracts of country, the improve-

ment of the finances, and the furtherance of education. An agitation for a constitutional reform, which purposed to replace the old diet of four estates by a directly elected parliament, was begun in this reign. But it was not carried until after Oscar I. (1844–59) had ceased to be king and Charles XV. (1859–72) had sat on the throne for seven years. The era of commercial and industrial activity set in in Sweden about the middle of the 19th century; and the national representatives into whose hands power passed with the new constitution—the peasantry and bourgeoisie—have confined their attention to such matters as railway construction, the discussion of free trade and protection, army reform, national insurance for working-men, and so forth. Sweden has enjoyed uninterrupted peace since 1814, although she approached the brink of war with Prussia (on behalf of Denmark) in 1848, with Russia at the time of the Crimean war and again during the Polish rising of 1863, and with Prussia and Austria in 1864. Of late years, especially since 1891, some internal difficulties have arisen through the Norwegians insisting on greater independence. In 1898 the Norwegian committee recommended the common consular representation for fifteen years only, aiming at an entirely separate system. They also rejected the Swedish proposal for a common defence, and adopted a purely Norwegian flag.

See Montelius, *Civilisation of Sweden in Ancient Times* (trans. 1888); Otté, *Scandinavian History* (1875); the histories (in Swedish) by Strinnholm, Geijer, Fryxell, and Carlsson; and the articles on GUSTAVUS ADOLPHUS, CHARLES XII., &c.

Literature.—Setting aside what was written in the Old Norse tongue (see ICELAND, DENMARK, RUNES), there is very little Swedish literature before the Reformation, except a few provincial law-codes, translations of French romances, some folk-songs, chronicles, religious and devotional works, and translations of parts of the Bible. Olans and Laurentius Petri (q.v.) brought the Reformation doctrines into Sweden, translated the Bible into good Swedish, and manifested an enlightened regard for their mother-tongue. For several years the principal books were theological and historical, such as the sermons of Matthiä (1592–1670) and Svedberg (1653–1735), which are still read. King Gustavus Adolphus founded the library at Upsala and gave direct encouragement to historical research, as by employing Schroderus (died *c.* 1650) to translate foreign historical works. Messenius (1579–1637) wrote an ambitious history of Sweden in Latin, and illustrated it by a series of historical plays in Swedish, that stood in high repute for more than a century. Political pamphlets and newspapers began to appear about the time of the Thirty Years' War. Bure or Buræus (1568–1652), besides constructing a fantastic scheme of universal knowledge, did sound work in Swedish mythology and language (runes).

But the title of 'Father of Swedish Literature' is usually accorded to Stjernhjelm (1598–1672), who composed didactic and humorous poems in the style of the classic epics. Baron Rosenhane (1619–84), in sonnets (*Venerid*), songs, and lyrics, composed in the manner of the French and Italian Renaissance writers, and 'Eurelius' or Dahlstjerna (1658–1709), in a patriotic epic (*The King's Poet*), and in heroic songs, strove to improve the current standards of literature. The Finlander Frese (1691–1728), who wrote very fair poetry, and Sweden's first satirist, Triewald (died 1743), who attacked the older writers, carry us on to Dalin (1708–63), who used his mother-tongue with an elegance and ease never previously attained. The *Argus* was conducted by him in the style of Addison's *Spectator*, and of his other works may be mentioned the witty allegories *Swedish Freedom* and *Saga about a Horse*. Hedvig Nordenflycht (1718–63) won great fame by her *Sorrowing Turtle-Dove*, a collection of *in memoriam* lyrics. After Dalin's death the leading poets were Count Creutz (1729–85), a Finlander, whose pastoral idyll *Atis and Camilla* was long admired, and Count G. F. Gyllenborg (1731–1808), though none of his books take very high rank. In prose the most notable writers were Mörk (died 1763), author of a didactic romance in the French style, *Adalrik and Gothilda;* Wallenberg (1746–78), who wrote an original work of travel (*My Son at the Galleys*), and the best tragedy (*Susanna*) in the pseudo-classic style since Dalin; and Count von Höpken (1712–89), composer of elegant *éloges* and rhetorical addresses.

But the strength of Swedish intellect in the 18th century seems to have been chiefly expended in the departments of science, as the following names conclusively attest—the Elder Rudbeck (1630–1702), a man of universal scientific attainments and author of *Atland or Manheim* (in both Swedish and Latin), a book, learned, bold, imaginative, written to prove the identity of Sweden with the Paradise of the Bible as well as with the Atlantis of Plato; the Younger Rudbeck (1660–1740), a botanist; Celsius (1701–44), whose name is perpetuated in the thermometric scale; the traveller Forskål (1732–6); Rosén or Rosenstein (1706–73), the founder of Swedish medicine; the great Linnæus (1707–78); the chemists Bergmann (1735–84) and Scheele (1742–86); and Ihre (1707–80), who compiled the first Swedish dictionary. The mystic Swedenborg (1689–1772), who, however, wrote in Latin, also belongs to this period.

The golden age of Swedish literature is coincident with the reigns of Gustavus III. and IV. (1771–1809). On its threshold stands Bellman (1740–95), an improvisatore of the highest genius. His finest work is *Fredman's Epistles*, songs that for gay humour and witty observation are unmatched in the language. Gustavus III., besides the direct and substantial encouragement he gave to the best literary talent amongst his subjects, founded the Swedish Academy (1786), and tried his royal hand at the drama. The foremost *littérateur* of his reign was Kellgren (1751–95), who made the *Stockholm Post* the supreme organ of literary taste in Sweden. In its pages a memorable feud was fought out between the writers of the old (Lutheran) school and the champions of revolutionary views borrowed in great part from the French encyclopædists. With this, however, a purely literary conflict was intertwined, carried on between the partisans of the pseudo-classic standards and the advocates of nature and romanticism. Kellgren, who adhered to the pseudo-classic (French) models, excelled in satiric and lyric poems: his *New Creation* is esteemed one of the finest poems in the language; and in conjunction with the king he composed two lyric dramas, *Gustaf Vasa* and *Christina*. Kellgren's ablest ally was Leopold (1756–1829), a master of polished prose, an excellent critic, and formidable and unsparing satirist, who wrote also in verse—odes, narrative and didactic poems, and weak pseudo-classic dramas. Their principal opponent was Thorild (1759–1808), who urged his contemporaries to cultivate something besides mere form, to emancipate themselves from the trammels of rule and law, and draw inspiration directly from nature. Nevertheless the standards of his rivals, although somewhat modified, continued for many years, chiefly through the Academy, to govern the taste of Swedish writers. Besides the three principal contestants the following participated in the fray: Rosenstein (1752–1824), who wrote on æsthetic and popular philosophic themes; Adlerbeth (1751–1818), author of

some successful classic dramas and of greatly admired translations of Virgil, Horace, and Ovid; Count Ehrensvärd (1745–1800), whose æsthetic writings are couched in excellent Swedish prose; Count Oxenstjerna (1750–1818), famous for poetic descriptions of nature and humorous and didactic poems, as well as for a good translation of *Paradise Lost*; the poet Lidner (1759–90); and a couple of humorous writers—Kexél (1748–96) and Hallman (1732–1800). Lindegren (died 1815) wrote comedies in the light and sentimental style of Kotzebue. Höijer (1767–1812) is perhaps the ablest and most original philosophical thinker Sweden has produced.

After Leopold's death the mantle of his literary dictatorship was divided between Anna Lenngren (1754–1817) and the Finlander Franzén (1772–1847). The lady, a typical Swedish nature, celebrated the virtues of domestic life with great truth and much poetic feeling. Franzén's lyrics excel in the best qualities of the poets of Finland—a pious naïveté, depth and refinement of feeling, simplicity and clearness of language, and great beauty of versification. Moreover he wrote very good prose (biographies). He is the main link between the Gustavian Academicians and the romantic schools. Archbishop Wallin (1779–1839), besides other poetry, wrote admirable hymns.

Very early in the 19th century ideas akin to those of the German romantic school were promulgated in Sweden by Hammarsköld (1785–1827), a good critic and historian of literature; Livijn (died 1844), author of some extravagant romances and songs; and Askelöf (1787–1848), editor of the magazine *Polyfem*, which, until it was supplanted by *Fosforos*, was the literary organ of the new school. These innovators encountered a good deal of ridicule from the old school, especially from Wallmark (died 1858); and for a time another literary war was waged. But this time the new way of looking at things proved too strong for the Academic champions. The romanticists received valuable support from Atterbom (1790–1855), one of the best lyric poets (cf. *Fågel Blå*, *Sångerlott*, &c.) of Sweden; from Palmblad (1788–1852), who wrote good romances (*Falkensvärd* and *Aurora Königsmarck*) and clever polemical and miscellaneous works; Dahlgren (1791–1844), whose satire approaches Leopold's and Kellgren's in wit and polish, and whose humorous poems and novels recall Bellman's happiest effusions; Börjesson (1790–1866), the author of one of the best dramas (*Erik XIV.*) in the Swedish tongue; and Agadh (1785–1859), a distinguished publicist. This movement dethroned didactic and pastoral in favour of lyric and epic poetry. There was, however, a richer and more momentous tendency operating contemporaneously with the romantic movement. Atterbom indeed directed attention to the ancient Scandinavian mythology, but it was Geijer (q.v.), no less eminent as a poet than as a historian, who pointed to the manly virtues of the Swedes' ancestors as models for imitation and sources of poetic inspiration. Tegnér (q.v.) showed in his early poems considerable sympathy with the approved Academic standards; but eventually he moved into line with Geijer, and thus stationed himself midway between the pseudo-classic and romantic schools. Around these great leaders of the 'Gothic revival' were grouped a crowd of less gifted writers, the more noteworthy of whom were Ling (1776–1839), who, although he wrote one good drama (*Agne*) and some poems, is best remembered as having convinced his countrymen of the educative importance of gymnastics; Nicander (1799–1839), a lyric poet and author of a promising tragedy; Beskow (1796–1868), a biographer and excellent dramatist (*Thorkel Knutsson*); Afzelius (1785–1871), who composed sentimental tales in melodious verse and along with Geijer edited the first collection of Swedish folk-songs; and Gumælius (1789–1877), the writer of a first-rate historical novel (*Thord Bonde*, in 1828). Next came half-a-dozen authors who stood more or less apart, each by himself. Almqvist (1793–1866), a man of brilliant genius and almost universal knowledge, and master of an exquisite style, excelled, despite his ultra-romanticism, in nearly all departments of literature; his best books are novels (*Book of the Rose* and *The Palace*). Stagnelius (1793–1823), another pronounced romanticist, is esteemed one of Sweden's best lyric poets, chiefly on the strength of the mystic *Lilies in Sharon*; an almost equal excellence distinguishes the grand epic *Vladimir the Great* and the dramas *The Bacchantes* and *The Martyrs*. The satires of Sjöberg or 'Vitalis' (1794–1828) compare not unfavourably with those of Leopold. Satire, too, is the principal note in Bishop Fahlcrantz's (1790–1866) *Noah's Ark*, and in the witty but often coarse improvisations of Wadman (1777–1837) and Detlof von Braun (1813–60). Cederborgh (1784–1835), although he wrote celebrated romances (*Uno von Trascnberg*, *Ottar Tralling*), does not belong to the romantic school. Böttiger (1807–78) and B. E. Malmström (1816–65) published poetry of more than average merit. 'Talis Qualis' or Strandberg (1818–77), besides writing the satirical and fiery *Songs in Harness*, made an excellent translation of Byron. Wennerberg's (born 1817) student-songs take the same place in Sweden as Von Scheffel's do in Germany.

But a long way the most illustrious poet of the 19th century was the Finlander Runeberg (q.v.), a man of almost the highest poetic genius. The most prominent of the more recent poets are the Swedes Count Snoilsky (born 1841), Rydberg (1829), and Bååth (1853), and the Finlanders Topelius (1818) and Tavaststjerna (1860). Amongst the remaining poets of the same period may be mentioned Sturzén-Becker or 'Orvar Odd' (1811–69) and King Oscar II. (1829). The 19th century has more than atoned for the paucity of novelists in its predecessors. Amongst the earliest to write in the modern spirit was Sophia von Knorring (1797–1848), who described the domestic life of aristocratic circles. But she is overshadowed by Frederika Bremer (q.v.) and Emilie Flygare-Carlén (1807–92), whose stories of the western skerries (*A Merchant's House in the Skerries*, *The Rose of Tistelön*) were deservedly very popular. Other female novelists of repute are Sophia Schwartz (born 1819); Frederika Runeberg (1807–79), wife of the poet; Fru Kerfstedt (1835); and Helene Nyblom (1845). Of the sterner sex Mellin (1803–76) and Sparre (1790–1871) cultivated the historical novel with more or less success. Wetterbergh or 'Uncle Adam' (1804–89) was a warm favourite for his democratic tales and his simple and humorous *Genre Pictures* of Swedish life. Rydberg the poet won fame also for his semi-historical novels (*The Last Athenian*, *Roman Days*) and learned works on Scandinavian mythology. Crusenstolpe (1795–1865) and 'Orvar Odd' are, like Rydberg, held up as models of Swedish prose—the former in novels, the latter in sketches and vignettes of Swedish life and in essays and critical papers. The poet Topelius has produced what are perhaps the most artistic historical novels in modern Swedish literature: his (prose) *Army Surgeon's Stories* ranks with Runeberg's *Ensign Stål's Tales*.

The light comedies of Blanche (1811–68) and of Jolin (1818–84), as well as the short stories and sketches of the former, run in the same vein of moderate romanticism that distinguishes the novels of 'Uncle Adam' and the verse of 'Talis Qualis' and 'Orvar Odd.' The plays of F. Hedberg (born

1828) are somewhat more serious in aim. F. A. Dahlgren translated Shakespeare, Calderon, and Heiberg (Dane), and wrote a good popular play (*The Vermlanders*) and memoirs of the Stockholm stage. The poet Bäckström (1841–86) has written some good lyric dramas.

In quite recent years a whole literature has grown up out of the social problems and discussions of the day, especially the questions of literary realism *versus* idealism and of the relations of the sexes. The novel and the drama are the favourite forms of this literature; and deep earnestness, often bitter and pessimistic in mood, and a keen spirit of contention characterise most of its writers. The foremost in this 'modern' movement is Strindberg (q.v.); his fellow-workers, or more frequently antagonists, are Nordensvan (born 1855); Af Geijerstam (1858); Tor Hedberg (1861), one of the most promising of the younger writers; Levertin, the poet; Anna Edgren (1849), in descriptions of Stockholm society and in plays; Fru Agrell (1849), a playwright; Victoria Benedictsson or 'Ernst Ahlgren' (1850–88), in the excellent novels *Fru Marianne* and *Money;* and Matilda Roos (1852), a novelist. Molander (1858) has begun a promising career as a dramatist. Two novelists of promise have come forward recently—Af Heidenstam and Selma Lagerlöf (*Gösta Berlings Saga*). Lundqvist, Bondeson, and Hedenstjerna or 'Sigurd' enjoy considerable popularity as writers of fiction in a minor key.

The chief representatives of the more special departments of literature during the 19th century can only be briefly enumerated. Historians: Geijer (q.v.), Fryxell (q.v.), Strinnholm (1786–1826), Carlsson (1811–87), Axelson, Odhner (born 1836), and Bååth; the principal historians of literature are quoted in the bibliography subjoined to this article. Literary critics: Ola Hansson and the Finlander Vasenius. The ancient civilisation and antiquities of Sweden: Montelius (born 1843), H. Hildebrand (1842), B. E. Hildebrand (1806–84), Nilsson (1787–1883), Rydberg, and Nyström. Church History: Cornelius (born 1828), Reuterdahl (1795–1870), and Anjou (1803–84). In public affairs and economics the writings of H. Järta (1774–1847), L. Järta (1801–72), and Agardh (1785–1859) rise above the average level. Boström (1797–1866) was an able philosopher. The most popular writers of devotional and religious books have been the poet Franzén, Schartau (1757–1825), Wallin, and Thomander (1798–1865). Philology boasts of Rydqvist (1800–78), Säve (1812–76), and Rietz (1815–68); law and jurisprudence of Schlyter (1795–1888) and Holmbergsson (1764–1842); ethnology of Retzius (1796–1860); botany of Fries (q.v.); chemistry of Berzelius (q.v.); and geographical exploration of Nordenskiöld (q.v.).

Schück, *Svensk Literatur-historia* (Stockh. 1886 *et seq.*); Fryxell, *Bidrag til Sveriges Literatur-historia* (1860–62); Malmström, *Granddragen af Svenska Vitterhetens Historia* (1866–68); Wieselgren, *Sveriges Sköna Literatur* (1843–49); and consult Schweitzer's useful *Geschichte der Skandinavischen Literatur* (Leip. 1886–89), and Vasenius, *Lärobok i Sveriges og Finlands Literatur-historia* (1887).

Swedenborg, Emanuel, was born in Stockholm, January 29, 1688, and died in London, March 29, 1772. His father was Jesper Svedberg, subsequently Bishop of Skara. Swedenborg's lifetime divides itself into two distinct periods; the first, ending with his fifty-fifth year, was given to business, science, and philosophy; the second, of nearly thirty years, was devoted to theology and spiritual communion. Swedenborg was educated at Upsala, and subsequently travelled for four years in England, Holland, France, and Germany. On his return to Sweden he was appointed by Charles XII. an assessor in the College of Mines, and rendered some service to that monarch at the siege of Frederikshall as military engineer. The family was ennobled in 1719, and the name changed from Svedberg to Swedenborg. Swedenborg is sometimes styled Count or Baron, but erroneously; he was neither, though he had a seat in the Swedish House of Nobles as the head of his family. His mind at this time was busy with mechanical and economical projects. He published short treatises on algebra, giving the first account in Swedish of the differential and integral calculus; on a mode of finding the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on the depth of the sea, and greater force of the tides in the ancient world; on docks, sluices, and saltworks; and on chemistry as atomic geometry. In 1724 he was offered the professorship of mathematics at Upsala, which he declined from a dislike of non-practical science. Abandoning desultory studies, he devoted himself for ten years to the duties of his assessorship and to a systematic study of the methods of mining and smelting at home and abroad, and to the construction of a theory of the origin of creation. The result appeared at Leipsic, at the expense of the Duke of Brunswick, in 1734, in three massive folios, beautifully illustrated, entitled *Opera Philosophica et Mineralia.* The second and third volumes describe the best methods employed in the manufacture of iron, copper, and brass. The first volume, entitled *Principia, or the First Principles of Natural Things, being new Attempts towards a Philosophical Explanation of the Elementary World,* is an elaborate deduction of matter from 'points of pure motion produced immediately from the Infinite.' This was followed in the same year by *Philosophical Argument on the Infinite, and the Final Cause of Creation; and on the Mechanism of the Operation of Soul and Body,* carrying the doctrine of the *Principia* into higher regions, and resolving the soul into points of motion, the soul being treated as one in substance with the sun. Dissatisfied with his conclusions, he determined to track the soul to its inmost recesses in the body. His studies in human anatomy and physiology with this end in view were embodied in his *Economy of the Animal Kingdom* (2 vols. 1741) and his *Animal Kingdom* (3 vols. unfinished, 1744–45).

At this point his course as a natural philosopher was arrested, and he entered on his career as spiritual seer. The particulars of the transition are recorded in his diary for 1743–44, and comprise a variety of curious dreams and strange communings; he now professed to enjoy free access to the spiritual world. He resigned his assessorship in 1747, that he might devote himself to the office to which the Lord had called him. In 1749 he made his first public utterance in his new character in the issue in London of the *Heavenly Arcana* (1749–56, 8 vols. 4to.). His life henceforward was spent chiefly between Stockholm, London, and Amsterdam, in writing and printing a variety of works in exposition of his experience and doctrines. There is little in any of these which is not to be found in outline at least in the *Heavenly Arcana,* and a note of its contents may serve, therefore, as a general description of the whole. With many digressions, the *Heavenly Arcana* is a revelation of the internal or spiritual sense of Genesis and Exodus. The early chapters of Genesis are a fragment of an older Word, preserved at this day in Tartary, and are an allegorical and not a literal history. Adam signifies the Most Ancient Church, and the Flood its dissolution; Noah, the Ancient

Church, which falling into idolatry was superseded by the Jewish. The spiritual sense pervades the Scriptures, which are the genuine Word of God, as the soul does the body. The exceptions are Ruth, the Chronicles, Ezra, Nehemiah, Esther, Job, Proverbs, Ecclesiastes, the Song of Solomon, the Acts of the Apostles, and the Epistles. These books have an edifying natural sense like other good productions of human authors, but, inasmuch as they do not possess the internal sense, they are not held to be inspired. The Scriptures are read in heaven in their spiritual sense, but, as that sense treats exclusively of God and man as a spiritual being, it is void of every reference to earthly scenes, persons, and events. By reason of its symbolism of the inward sense, the letter of Scripture is holy in every jot and tittle, and has been preserved in immaculate perfection since the hour of its Divine dictation. The Jewish dispensation having reached its period, God appeared in Jesus Christ; He assumed human nature in its humblest condition in the Virgin, wrought it into conformity with Himself, 'glorified and made it Divine.' The effluence from the Lord's Divine humanity is the Holy Spirit. In a sense the reverse of Socinian, Swedenborg was a Unitarian; he saw God in the Saviour, and regarded Him as the sole object of worship. The church initiated by the Divine Advent came to an end in the 18th century, and Swedenborg witnessed the Last Judgment effected in the year 1757 in the World of Spirits. Then commenced a new dispensation, signified by the New Jerusalem in the Revelation, of which Swedenborg was the precursor, and his writings contain the doctrine. To the objection, that the doctrine is strange and novel, he replied that mankind were not prepared for its reception before that time, and that the early Christians were too simple to understand it.

One object of his mission was the revival of the lost science of correspondences—the science of sciences in the most ancient times. The law of correspondence is universal; the natural world is the outbirth of the spiritual world, and the spiritual world of the invisible mental world. Unseen evil is manifested in things hurtful and ugly, unseen good in things useful and beautiful. Man is a summary of nature; nature is man in diffusion; all things, therefore, in nature—fire, air, earth, and water—every beast, bird, fish, insect, and reptile—every tree, herb, fruit, and flower—represent and express unseen things in the mind of man. The Scriptures are written according to correspondences, and by aid of the science their mysteries are unlocked. By it, too, the constitution of heaven and hell is revealed. There are three heavens, consisting of three orders of angels: the first distinguished for love, the second for wisdom, and the last for obedience. All angels have lived on earth; none were created such. They are men and women in every respect; they marry and live in societies in cities and countries just as in the world, but in happiness and glory ineffable. All in whom love to God and man is the ruling principle go to heaven at death. Between heaven and hell a perfect equilibrium is maintained. As there are three heavens so there are three hells, and every angelic society has an infernal opposite. Hell, as a whole, is called the Devil and Satan; there is no individual bearing that name. All in whom self-love is the ruling motive go to hell. There is no resurrection of the earthly body. Every one passes to his final lot at death, some making a short sojourn in an intermediate state, designated the World of Spirits, where the good are cured of their superficial infirmities and intellectual errors, and where the evil are stripped of all their pretences to good. Swedenborg's other notable works (all first published in Latin) are *Heaven and Hell, The New Jerusalem and its Heavenly Doctrine, Angelic Wisdom concerning the Divine Love and the Divine Wisdom, Angelic Wisdom concerning the Divine Providence, The Apocalypse Revealed*, and *The Delights of Wisdom concerning Conjugal Love;* his whole translated theological works numbering forty volumes of a good size.

Swedenborg professed to enjoy acquaintance with many departed celebrities, and some of his verdicts on character reverse the estimates of history. Nor was his intercourse confined to spirits from earth, but extended to souls from the moon and the planets. For these visions, experienced whilst sitting in his chamber, he had this explanation: although in the spiritual world there are *appearances* of space, there is nothing of the objective reality which here divides London from Melbourne. If one spirit desires to see another, the desire instantly brings them together. A good man is, as to his mind, in heaven, and an evil man in hell; and supposing the spiritual sight of either were opened—i.e. if the eyes of the spiritual body, which transfuse and animate the material ones, were disengaged from their fleshly vesture—he would see his spiritual companions and the country where he would abide after death.

The grand and distinctive principle of Swedenborgian theology, next to the doctrine of the Divine Humanity, is the doctrine of life. God alone lives. Creation is dead—man is dead; and their apparent life is from the Divine presence. God is everywhere the same. It fallaciously appears as if He were different in one man and in another. The difference is in the recipients; by one He is not received in the same degree as another. A man more adequately manifests God than a tree; that is the only distinction. The life of devils is God's presence perverted in disorderly forms. 'All things, and each of them to the very uttermost, exist and subsist instantly from God. If the connection of anything with Him were broken for a moment it would instantly vanish; for existence is perpetual subsistence, and preservation is perpetual creation.' By this law of life is explained man's self-consciousness, freedom, and personality—notions communicated from God to man.

Swedenborg made no attempt to establish a sect. When he proclaimed the Christian Church at an end, his expectation was that a new church would be raised up among the Gentiles; but towards the close of his life he spent his energies in attacking orthodox theology, Catholic and Protestant, as if bent on the conversion of Christian lands, but especially of northern Europe. All his works were written in Latin, and received small measure of attention from his contemporaries. Swedenborg was shrewd in worldly affairs, affable in society, and discussed politics and finance in the Swedish Diet like a man of the world, and that for nearly a score of years after he began to write and publish his theological works. He was never married. His diet was chiefly but not wholly vegetarian.

The Swedenborgians, or, as they designate themselves in their corporate capacity, 'The New Church signified by the New Jerusalem in the Revelation,' were first organised as a distinct denomination in 1788 by Robert Hindmarsh (1759–1835), a printer in Clerkenwell, who became one of the first ministers of the body. The Swedenborgians accepted Swedenborg's voluminous theological writings as containing a revelation from heaven. The body has grown steadily but not quickly. The number of its registered members in Britain in 1891 was 6239, divided into 75 congregations, chiefly in the large towns and in Lancashire; five are in Scotland, one in Wales, but none in Ireland. Their General Conference holds £66,431 invested on behalf of

various missionary and church uses. There have always been a number of receivers of the doctrines of Swedenborg among the clergy of the Church of England. The first translator of the *Heavenly Arcana* and many of the other theological writings of Swedenborg was the Rev. John Clowes (1743–1831), rector of St John's, Manchester, for sixty-two years, who both in the pulpit and in his numerous publications made no secret of his faith. From the first those who accepted Swedenborg's teachings have been divided into separatists and non-separatists. In the United States the Swedenborgians have 104 societies and 5803 members, chiefly in the northern states; the largest congregation is in Boston. In France, Germany, Switzerland, Sweden, Denmark, Italy, and Russia there are Swedenborgians, but they are so few and scattered that there are but eight congregations in these countries which meet for divine worship every Sunday. There is a Swedenborg Society, established in 1810, for printing and publishing Swedenborg's works, with a house in London, and an income of about £600 a year. They have a National Missionary Institution and eight local missionary committees, a training college for their ministry, and an orphanage.

See the biographies of Swedenborg by W. White (Lond. 1867), by J. J. Garth Wilkinson (1886), and *Documents concerning the Life and Character of Swedenborg*, by Professor R. L. Tafel (3 vols. 1875–77).

Sweeps are oars of great length used during a calm or in still water, either to assist the rudder or to propel the vessel. See also CHIMNEY.

Sweepstakes, a method of gambling by which several persons contribute each certain stakes, the whole of which fall to one when a certain event happens. In the case of horseraces, each contributor gets either a horse or a blank (by lot or otherwise), and the one whose horse wins takes the stakes, though often the other horses that are 'placed' secure a share for those who have drawn them. Raffles and sweeps are illegal, though constantly carried on without interference from the authorities (see GAMBLING). The Pari-Mutuel is a kind of sweepstakes (see BETTING).

Sweet Bay. See LAUREL. For Sweet Brier, see ROSE; and for Sweet Flag, CALAMUS.

Sweetbread, the Pancreas (q.v.) of an animal, used as food; it is highly esteemed as being both delicate and nutritious.

Sweet Pea (*Lathyrus odoratus*), a familiar garden annual plant belonging to the natural order Leguminosæ. It is a native of Sicily and other parts of the south of Europe, and has been cultivated for its beautiful and fragrant flowers in British gardens for about two hundred years. The varieties are very numerous, distinguished chiefly by the different shades of colour of the flowers. It is cultivated as a hardy annual, and is so hardy that it may be sown in autumn and will not only withstand the cold of winter in all but the coldest districts, but will bloom earlier and better than when sown only in spring. Sowing in the latter season is, however, necessary to provide prolongation of bloom. Other species of Lathyrus are of interest either as ornamental plants or for the food for man or cattle which they yield. The Everlasting Pea (*L. latifolius*) is an old favourite in flower-gardens on account of its handsome but scentless flowers. The roots of *L. tuberosus* are eaten in Holland and other countries where it grows plentifully. The Chickling Vetch (*L. sativus*) is much used in Switzerland as fodder for cattle. The seeds ground into meal make palatable bread, but to its use was ascribed sudden attacks of loss of power and rigidity of the limbs in both men and the lower animals, which were so prevalent in the latter part of the 17th and early in the 18th century that an edict was issued forbidding its use. Mixed with half the quantity of wheat-flour it is said to be wholesome; the peasantry in Italy use it in this way.

Sweet Potato (*Batatas*), a genus of plants belonging to the natural order Convolvulaceæ. *B. edulis*, the true sweet potato, is a twining or climbing plant, with stems 5 or 6 feet long trailing on the ground or clambering over neighbouring shrubs. The leaves are 5 or 6 inches long, heart-shaped at the base; the flowers pale purple, closely resembling those of the common convolvulus or bindweed. Having been long cultivated in the tropical and subtropical countries of both hemispheres, the native country of the plant is a matter of conjecture. It appears to be first mentioned by Pigafetta, an author of the 16th century, who found the root much used by the Indians of Brazil as an

Sweet Potato (*Batatas edulis*).

article of food. It was introduced into Spain about 1519, and the roots were known in England some time before the introduction of the potato, with which they were often confounded by the earlier writers on the latter. English supplies in those times were obtained from Spain and the Canary Islands, and the roots, when steeped in wine or made into sweetmeats, were regarded as restorative of failing vigour. The plant is cultivated in India, China, Japan, the Malayan Archipelago, throughout tropical America, and in the southern United States, in southern Europe, the Canary Islands, Madeira, and North Africa. The roots grow to a great size—to as much as 50 lb. weight, according to some authorities, in Java, but the ordinary average is from 3 to 12 lb. In favourable conditions in the United States the yield per acre is from 200 to 300 bushels. The taste of the roots is sweetish and agreeable, and they are considered to be superior to the common potato in flesh-forming matters. *B. jalapa*, a species of Mexico, though purgative, is not the source of the true jalap of the pharmacopœia, as its name implies, but is so called on account of its being very common in the vicinity of the Mexican town Jalapa. *B. paniculata*, which has a very wide geographic distribution, is commonly cultivated for food in western tropical Africa. From the seeds of another species of Batatas the textile material named Natal Cotton is obtained; it has some resemblance to the true cotton.

Sweet William. See PINK.

Swetchine, MADAME (*née* Soymanof), was born at Moscow in 1782, joined the Roman

Catholic communion under the influence of Joseph de Maistre in November 1815, and settled in France about the end of 1816, dying at Paris in 1857. For about forty years she maintained at Paris a famous salon, characterised by the remarkable peculiarity of a distinctly theological bias. Her husband, General Swetchine, was a quiet, inoffensive man, twenty-five years her senior; she herself was small and plain, with a Calmuck nose and ill-matched eyes; yet she possessed a spiritual beauty and a charm of personality of altogether unusual kind. Her passionate nature had early found safety and perhaps happiness in rigidity of principle and an austere love of heaven; she never had a child; and almost from youth until the end her life was marked with more than the enthusiasm of the convert. Yet she tempered the ardour of zealous and propagandist orthodoxy with all the courtesy of the great world. The church had granted her the rare indulgence of a private chapel in her house, and from the dialectic play of intellect in the salon she passed easily to rapt worship and spiritual communion with God. Her letters and writings, such as those on Old Age and Resignation, show subtle thought and elevation of tone, if scarcely distinction of style, but lack the peculiar charm that belonged to her personality, and scarcely justify the enthusiasm of her group of friends whose admiration soon passed into worship.

See M. de Falloux, *Madame Swetchine, sa Vie et ses Œuvres* (2 vols. 1860), and her Lettres, by the same editor (2 vols. 1861); also Sainte-Beuve, in *Nouveaux Lundis*, vol. i., and E. Scherer, in *Études sur la Littérature Contemporaine*, vol. i.

Swietenia. See MAHOGANY.

Swift, a genus (Cypselus) and family (Cypselidæ) of Picarian birds, resembling the swallows in general appearance and habits, but most closely allied by anatomical structure to the humming-birds. They may be distinguished by external characters from swallows thus: 'the swifts have ten primaries, not more than seven secondaries, and only ten tail-feathers, while the swallows have but nine primaries, at least nine secondaries, and twelve tail-feathers.' They have long pointed wings, a short tail, and possess remarkable powers of rapid and prolonged flight. The bill is short, depressed, and weak; the gape wide and fringed by bristles. The legs and toes are short and weak. In distribution the swifts are almost cosmopolitan, but are absent from New Zealand. Two groups are recognised, (*a*) the Micropodinæ, or true swifts, with the first toe directed more or less forwards, and a reduced number of phalanges in the third and fourth toes, and (*b*) the Chæturinæ, with the first toe directed backwards and the normal number of phalanges in the third and fourth toes. The Common Swift (*Cypselus apus*) is common in almost all parts of the north of Europe and Asia in summer, retiring to tropical or subtropical regions in winter, extending its migrations to the extreme south of Africa. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of notice that the swift is seldom to be seen along with any of the swallows or martins, the different kinds choosing different localities, even although very close together. The swift is easily recognised in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is bronzed blackish brown, with a white throat; bill, toes, and claws black. It makes its nest in holes in rocks and walls, often in the thatch of houses, crevices in sea-cliffs, quarries, chalk-pits, and trees. The nest is formed of bits of straw, dry blades of grass and bents, feathers, and other such substances, which are apparently glued together by a viscid secretion. The eggs are two in number, and as a rule only one brood is hatched in a season. The swift, like the swallow, seems to return to the same place to nest year after year, and repairs the old nest instead of making a new one. Sometimes it robs martins, sparrows, and even starlings of their nests. Its chief food consists of insects, and the undigested remains are ejected in the form of pellets. The Alpine Swift, or White-bellied

Common Swift (*Cypselus apus*).

Swift (*C. alpinus*), is rarely seen in Britain, but is common in summer on all the high mountain-ranges of southern and central Europe. Eastwards it ranges through Asia Minor and Persia to many parts of India and Ceylon. It is supposed to breed in the extreme south of Africa, where it is common. It builds in high rocks, sometimes in steeples, notably in the cathedral at Bern. It is larger than the common swift, and has a louder note and flies more powerfully. The Needle-tailed Swift (*Acanthylis caudacuta*), an Asiatic species, has been twice found in England, each time in the month of July, but nowhere else in Europe. It is common during summer in south-eastern Siberia, Mongolia, Japan, China, and Tibet; while in winter it migrates as far south as to Eastern Australia and Tasmania. The American Swift (*Chætura pelagica*) has the hind-toe directed backwards, and the tail-feathers stiff and pointed, as in woodpeckers. It is a small bird, not above $4\frac{3}{4}$ inches in entire length, but one foot in extent of wing. The general colour is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of a viscid secretion to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys this species is known as the *Chimney-swift* in North America, where it is a regular migrant in many parts, wintering in Mexico. Great numbers often build together, sometimes choosing for this purpose an unused chimney in a town. The Swiftlets, genus Collocalia, found from India to the Malay Archipelago and in many of the Polynesian islands, one species even in Madagascar, are the builders of Edible Nests (q.v.). They breed in deep caves and fix their gelatinous-looking nests, made of mucus unmixed with any vegetable product, to the walls. The nest of one of the true swifts (*Panyptila sancti-hieronymi*) discovered in

Guatemala is perhaps still more remarkable, being composed entirely of the seeds of a plant secured together and hung from the under surface of an overhanging rock by the saliva of the bird. 'The whole forms a tube 2 feet 2 inches long by about 6 inches in diameter. The entrance is through the lower end of the tube, and the eggs are placed on a shelf at the top. About the middle of the tube, on the external side, is a protruding eave as if overvaulting an entrance; but there is no hole, and it has the appearance as if it was placed there on purpose in order to deceive some enemy, such as a snake or lizard,' especially during the period of incubation. The Palm Swift of Jamaica (*Micropus phœnicobia*) is also a remarkable nest-builder, attaching its nest of feathers and silk-cotton, felted together, to the surface of a spathe or of a leaf by means of its salivary secretion.

Swift, JONATHAN, Dean of St Patrick's, and the greatest of English prose satirists, came of a Yorkshire clerical family on his father Jonathan's side, while his mother was Abigail Erick of Leicestershire. He was thus related to two English poets, as a Swift to Dryden—for his grandmother was niece to the poet's grandfather, and as an Erick or Herrick to the author of the *Hesperides*. Jonathan Swift was born on 30th November 1667, seven months after his father's early death, at 7 Hoey's Court, which formerly stood near the Castle at Dublin. The only other child was his elder sister Jane. Left with the miserable provision of twenty pounds a year, his mother returned to her family in Leicester, leaving her son's education to the care of his uncle Godwin Swift, who sent him at the age of six to Kilkenny School (then the best in Ireland), where he had Congreve for a schoolfellow, and in 1682 entered him at the age of fourteen at Trinity College, Dublin. His college career was desultory, probably wild, and certainly unsuccessful; and he only obtained his degree *speciali gratiâ* in 1686. Two years later the turmoil of the Revolution drove him to England, where in 1689 he was received as secretary into the household of the distinguished statesman Sir William Temple (q.v.)—a distant connection of his mother—at Moor Park in Surrey. His proud and independent nature, however, rebelled against the subserviency of the occupation, and after declining a captaincy of horse offered him by William III., who visited Temple's house, and also a clerkship in the Irish Rolls Office tendered by his employer, he left Moor Park for Dublin, where he took orders (deacon, October 1694; priest, January 1695), and was presented by the Lord Deputy to the prebend of Kilroot, near Belfast, of the value of £100 a year. Country obscurity soon proved even less to his taste than waiting upon a great man's literary inspirations, and he was not sorry in 1696 to resign his prebend and accept Temple's invitation to return to Moor Park and help him with his papers. By this time Hester Johnson (born at Sheen, 13th March 1681)—immortalised by Swift under the name of Stella—the daughter of a gentlewoman who acted as companion to Lady Giffard, Temple's widowed sister, had grown up into a charming, beautiful, and intelligent girl, and the kindly solicitude of the young Irishman who guided her education was developing into the enduring affection which became the happiness of their two lives. Swift remained at Moor Park till Temple's death in 1699, when he received a legacy of £100 and the privilege of publishing Sir William's posthumous works (which he brought out between 1700 and 1720). His long residence in the house of a cultivated man of the world, despite the subordination that chafed his sensitive pride, had been useful to him. He had found leisure to study; he read enormously in classical and historical literature; he had been brought into personal relations with the king and the ministers, and had learned the business of the politician, which he was soon to practise with signal success. Moreover, the quiet retirement of Temple's house and the solitude of his Irish cure had given him time to produce a masterpiece and a brilliant *tour de force*—the *Tale of a Tub*, and the *Battle of the Books*. The former is held by some critics to be the greatest of Swift's satires; in style and as an artistic whole it certainly stands first. In none of his works is the satire more pointed, the thought more vigorous, the language more nervous and sustained. The cant of religion, the pretensions of letters, the hypocrisies of every form of false virtue or genius are exposed with the keen enjoyment of the iconoclast; the mask is torn from the solemn shams of the world amid derisive laughter. The young genius rejoices in its strength, and spares nothing in its destructive work; and to many minds there is something repellent and sacrilegious in its handling of time-honoured beliefs and institutions, though no profanity was intended. The *Battle of the Books*, an admirable travesty of the idle controversy then waging between Temple, Wotton, Boyle, and Bentley, concerning the comparative merits of ancient and modern writers, is a much slighter work, but full of exuberant vitality and humour. Both were published anonymously, like almost all Swift's works, in 1704.

Copyright 1892 in U.S. by J. B. Lippincott Company

Soon after Temple's death, failing in his application to the court for preferment, Swift became secretary to Lord Berkeley, one of the Lords Deputies to Ireland, and his wit enlivened the society of Dublin Castle by such jests as the *Petition of Mrs Frances Harris* (1700), in verse, and the parody of Boyle, *A Meditation upon a Broomstick* (1704), in prose. After being disappointed of the deanery of Derry, he was given the vicarage of Laracor, near Trim, in West Meath, in 1700, and presented to a prebend in St Patrick's Cathedral; and in 1701 he took his doctor's degree at T. C. D. From 1701 to 1710 he divided his time between Laracor and London, where he was employed on ecclesiastical business by the Archbishop of Dublin, and where he contrived to live for half each year on £60. His reputation as a wit, and his suspected authorship of the *Tale of a Tub* and the *Battle of the Books* (to say nothing of his earliest publication, the *Dissensions in Athens and Rome*, a defence of Lord Berkeley, 1701), assured his position in society and in the clubs and coffee-houses, where he constantly spent his evenings with Addison, Rowe, Prior, Congreve, and every one else worth meeting, and found himself ever more and more in request. He now wrote his humorous squibs on the unlucky almanac-maker, Partridge, under the pseudonym of Isaac Bickerstaff, and vindicated his position and opinions as a churchman (sorely damaged by the free speaking of the *Tale of a Tub*) in the *Argument to Prove the Inconvenience of abolishing Christianity*, the *Project for the Advancement of Religion*, and the *Sentiments of a Church of England Man* (all in 1708). At Laracor he busied himself with improving the vicarage, church, glebe, and garden, of which he was fond. 'I stayed above half the time,' he says, 'in one scurvy acre of ground, and I always left it with regret.' The regret was heightened by the circumstance that 'Stella,' who had come to Ireland with her companion, Rebecca Dingley, by Swift's advice, after Temple's death, passed much of her time between Trim and Dublin.

For the next three years, from September 1710 to June 1713, Swift was chiefly in London, incessantly engaged in political work. The Whigs had

done nothing for him, and he detested their war-policy and their views on the church establishment. The Tories, on the other hand, were full of civility and deference, and longed to win his pungent pen to their cause. Moreover, Swift was personally attracted by the character of Harley, the Lord Treasurer, and a warm friendship soon sprang up between these utterly dissimilar natures. So Swift abandoned his neutral position and became a Tory, and taking over the editorship of the *Examiner*, which had languished in its early days under Bolingbroke and Atterbury, converted it into a deadly weapon of attack against the Whigs. Swift's *Examiners*, thirty-three in number (November 1710 to June 1711), may almost be said to have created the 'leading article' and established the power of the press. They are not remarkable for rhetoric or eloquence, but are simple plain trenchant statements of policy and criticisms of opponents, such as the honest country squire could understand, and would have made himself if he had known how. The backbone of Swift's policy was denunciation of the war party as a ring of Whig stockjobbers, who cared nothing for the country, but out of self-interest played into the hands of the Emperor and the Allies. He urged this view, together with his firm belief in the landed interest and the establishment, in numerous brief and telling skits and broadsides in prose and verse, besides several elaborate argumentative pamphlets, such as the *Advice to the October Club* (1712); *Remarks on the Barrier Treaty* (1712); and the *Public Spirit of the Whigs*, a crushing reply to Steele's *Crisis* (1714); but nowhere so ably and forcibly as in his political masterpiece *The Conduct of the Allies*, published on November 27, 1711, of which the second edition was sold out in five hours on December 1, and a seventh edition reached in the new year. These writings undoubtedly contributed to the overthrow of Marlborough and the conclusion of the peace of Utrecht in 1713. Among slighter satires of this time may be mentioned *The Virtues of Sid Hamet the Magician's Rod* (1710), directed against Godolphin, and the *Windsor Prophecy* (1711). Swift was also engaged preparing his *History of the Last Four Years of Queen Anne*, a laboured production, which was not published till much later; and he also wrote, under his own name, a *Proposal for correcting, &c. the English Tongue* (1712), which includes the oft-suggested notion of a national academy of letters. His life during these three eventful and laborious years is minutely recorded in his wonderful *Journal to Stella*, the most faithful and fascinating diary the world has ever seen, in which all his hopes and fears, his daily work and occupations, his growing influence with ministers, everything in short that he did and all that he thought, are set down in perfect honesty and with no thought of publication, but only for the sympathetic interest of his life-companion Hester Johnson. High affairs of state mingle with playful tenderness and the sweet familiarity of the 'little language,' with a natural charm and frankness which make the *Journal* unique.

Swift's reward for his unwearied labour on behalf of the Tory administration was poor enough. He had throughout kept his independence, and declined to accept the pay of the government like a hired hack. He waited for ecclesiastical preferment; but the queen would not bestow a bishopric on the author of the *Tale of a Tub*. At last in the evil days that preceded the fall of the ministry he was given the Deanery of St Patrick's at Dublin (April 1713), though he would rather have been sent anywhere else. A year later the crisis came; Harley (now Earl of Oxford) resigned, the queen died, the Whigs came into office, and Swift's prospect of political influence in London was gone forever.

A romantic episode in his London life had been the passion he inspired in Esther Vanhomrigh (b. 14th February 1692), whom in his usual fashion he called 'Vanessa,' a young girl whom he grew to know intimately at her mother's house in London in 1709–13. He had a fatal habit of playing the mentor to women without looking to the consequences, and there can be no doubt that he behaved with little circumspection in his relations with Vanessa. When he went to Ireland she followed him, and lived sometimes at Dublin and sometimes at a place she had inherited at Celbridge. Whether Swift was married to 'Stella' or not (and there is no satisfactory evidence for the alleged marriage in 1716), the presence of 'Vanessa' in Turnstile Alley, and of Stella in Ormond Quay, on the other side of the Liffey, must have been extremely embarrassing to the solitary tenant of the Deanery between the two; and there is no doubt that he tried to repress Vanessa's passion. She died of a consumption in 1723, and by her testamentary directions Swift's metrical version of their romance was published, with the title *Cadenus* [i.e. *Decanus*] *and Vanessa* (1726). But what his real relations were with the two women, why he did not marry, or, if he did eventually go through the mere ceremony with 'Stella,' as the legend tells, why he kept his marriage a profound secret, and why they never lived together, remain mysteries still, in spite of more than one plausible explanation. The theory that he believed himself tainted with hereditary madness, supported by the fact that he suffered from mysterious attacks in the head due to a disease in the ear, appears to furnish the best clue to his determination to abjure the privilege of fatherhood; and another reason for his abstinence, compatible with this, has been deduced from the fact that he seems to have never experienced the ordinary emotion of passion. Whatever his passing feeling for 'Vanessa,' there can be no doubt that he was devotedly attached to 'Stella' to her dying day (28th January 1728), and that in all senses but one few women have been better loved.

When his hopes of further political work in England were demolished by the accession of King George and the Whigs, Swift, now a man of forty-seven, retired to his deanery, and with the exception of two journeys to England in 1726 and 1727, and occasional visits to friends in Ireland, remained there for nearly thirty years. But political influence and activity were essential to his masterful nature, and accordingly he devoted his energies to the wrongs of Ireland, which were then very real indeed. He did this from no love of the land of his exile, nor out of sympathy with the true Irish: he considered Dublin merely 'a good enough place to die in,' and his voice was raised chiefly on behalf of the narrow Ireland of the Englishry. He defended Ireland only out of 'a perfect hatred of tyranny and oppression' wherever it was found. Nevertheless his ungracious mediation and his unpalatable home-truths bore marvellous fruit throughout the country; he created and guided popular opinion and for a while made it a power; and the generous impulsive populace worshipped him. His Irish tracts (of which the famous *Drapier's Letters*, 1724, directed against a supposed fraudulent introduction of a copper currency known as 'Wood's halfpence;' the *Proposal for the Universal Use of Irish Manufactures*, 1720; and the audacious *Modest Proposal* for utilising children as articles of food, 1729, are among the best examples) possess all the merits of his style and method, his inflexible logic, his delightful reductions to absurdity, his burning passion, his tremendous scorn, and his

unsparing virulence in attack. He brought the law upon his printer more than once, but he won the day. 'Wood's halfpence' were suppressed, and the Lord-lieutenant had to confess good-humouredly that he governed 'by permission of Dr Swift.'

Besides his Irish tracts, a good deal of light verse—never rising to the level of true poetry, and often exceedingly coarse—and his *Polite Conversation* (1738), a witty parody of small-talk, and *Directions to Servants*, a savage satire on menial incapacity, Swift's Irish period is notable for the completion of the most famous of all his works: *Gulliver's Travels* appeared in 1726, and was immediately in the mouth of all the world. This immortal satire needs no description or criticism. In it we see Swift's genius in its full maturity, less impetuous and fiery than in the *Tale of a Tub*, but sterner, more earnest, more majestic in its scorn. It is the terrible earnestness of Swift's indignation at the cant and shams of the world that gives his work its unique force and fire. But with all its deadly satire *Gulliver* is a wonderful story-book, and its daring fancy joined to a strange sobriety and plausibility, its bizarre situations, its inherent possibility, and its delightful playfulness make it a classic favourite with children, as well as men, to whom the scourge is more apparent than the jest. Swift's style is here seen in its perfection; pointed and direct, simple, masculine, absolutely free from affectation, logical and lucid, it always says just what it means, with never a word wasted; its shafts hit the mark fair in the centre with unerring precision.

Of his life during his later years a record is found in his voluminous correspondence with English friends like Pope, Gay, Arbuthnot, Bolingbroke, and his Irish crony, Dr Sheridan, to name no more. As letters alone they are quite admirable; but as biographical materials they are priceless. No man was staunchier in his friendships than Swift, and in spite of his bitter moods he hardly ever lost a friend. They were all he had to live for after 'Stella's' death, except his duties and charities among the poor in the Liberties of St Patrick, where he was adored. His life had become very lonely and sad, and he dwelt in constant dread of that mental overthrow which he felt was coming. In 1740 his brain disease drove him to the verge of madness, but after two years clouded by periods of unspeakable torment he sank into a helpless, speechless lethargy, and so gradually faded out of life. The long misery and despair, and lonely exile, and final torpor came to an end 19th October 1745, when the most commanding intellect of his time passed from its dreary prison of imbecility to where, in the words of his own epitaph, his *sæva indignatio ecr ulterius lacerare nequit;* and the body of the great dean was laid beside 'Stella,' in the same grave, in the cathedral over which he had reigned for thirty years.

The standard edition of the *Works of Swift* is Sir Walter Scott's (19 vols. Edin. 1814; 2d ed. 1824), which includes most of what was valuable in the earlier collected editions of Hawkesworth and Sheridan, but which stands in need of a thorough revision. Numerous selections from his works have been made; amongst them are those by the present writer, in two volumes, *Prose Writings* and *Journals and Letters* (Parchment Library, 1884 and 1885), with introductions, criticisms, and notes, which have been used in this article; by W. Lewin (Camelot Classics, 1886); by H. Morley (Carisbroke Library, 1889-90); and H. Craik (Clarendon Press, 1892). John Forster published the first volume of an exhaustive Life in 1875; that by Henry Craik (1882; new ed. 1894) became the standard. See also the short Life by Leslie Stephen (1882); the Life by Churton Collins (1893); Moriarty, *Dean Swift and his Writings* (1893); and R. Ashe King, *Swift in Ireland* (1896). The evidence for the supposed marriage with Stella has been sifted with a lawyer's acumen in *Blackwood's Magazine*, May 1876, by J. Paget, who decides against it. For separate editions of Swift's works, and where preserved, see *Notes for a Bibliography of Swift*, by the present writer (1884). Portraits of Swift are to be seen at the Bodleian Library, Oxford, by Jervas, at the Deanery of St Patrick's, at Howth Castle, in Lord Orrery's *Remarks*, and in Nichol's edition of the works.

Swilly, Lough, a long narrow inlet of the Atlantic on the north coast of Donegal, Ireland, enters between Dunaff Head on the east and Fanad Point, on which there is a lighthouse (fixed light visible 14 miles), on the west. A second lighthouse, on Dunree Head, has a fixed light visible for 13 miles. The entrance is protected by forts. Lough Swilly penetrates about 25 miles inland, and has a width of 3 to 4 miles. On the eastern shore is the small town of Buncrana, much resorted to for sea-bathing. On its waters a French fleet under Bompart was destroyed in 1798; and in 1811 H.M.S. *Saldanha* foundered at the entrance in a storm, and 300 lives were lost.

Swimming. From time immemorial the great usefulness of swimming has been universally acknowledged, and the ease with which the art of supporting the human body in water can be acquired is a statement as old as the hills. The absolute correctness of the assertion that there is no difficulty in the way of the individual who would become a swimmer is open to question, but it is certain that the number of those who surmount all obstacles grows larger year by year. This is due in no small measure to the greatly increased facilities for the pursuit of this most healthful and pleasurable pastime afforded by the erection of many additional and improved public baths; also to the extensive encouragement the sport receives from the numerous swimming clubs in existence. Valuable aid is given to those wishing to know how to swim by such works as Wilson's *Swimming Instructor;* but there is no teaching equal to that which is to be obtained in the water with a proficient as guide. The pupil's every movement is watched, mistakes pointed out, and a bad style avoided—a great thing if one wishes to share in the delights of competition, of which there are now so many opportunities. No greater stimulus was ever given to an art than Captain Matthew Webb (1848–83) gave to swimming when he crossed the English Channel in the water. How stupendous the feat was is explained by the time it occupied. Starting from the Admiralty Pier, Dover, on August 24, 1875, Webb swam or floated for 21 h. 45 m., in which time he reached Calais Sands, where his journey ended. By this feat, the greatest recorded, Captain Webb (drowned in his attempt to swim through the Niagara Rapids) made himself for ever afterwards famous. A notable long swim was accomplished on September 2, 1884, by Mr Horace Davenport, who held the title of amateur champion from 1874 to 1879 inclusive, and must be reckoned as one of the strongest of strong swimmers, his mile time in still water, 29 m. 25½ s., accomplished on August 11, 1887, remaining unbeaten by amateurs. Starting from the East Pier, Southsea, Mr Davenport crossed to Ryde Pier and then returned to the Clarence Esplanade Pier, Southsea, without resting, the double journey in a choppy sea occupying 5 h. 25 m. Other long swims, in which it will be seen ladies have played a prominent part, are as follows: 20 miles 3 furlongs, by F. Cavill, 5 h. 51 m., in Thames (with tide), July 8, 1876; 20 miles, Miss Agnes Beckwith, 6 h. 25 m., in Thames (with tide); 18 miles, F. Cavill, 5 h. 58 m., Yarra, Queensland, March 1879; 10 miles, Miss Agnes Beckwith, 2 h. 43 m., in Thames (with tide), July 5, 1876; 10 miles, J. B. Johnson, 2 h. 40 m., Delaware River, United States (with tide),

August 24, 1875; 9 miles, Miss Emily Parker, 2 h. 24 m. 30 s., in Thames (with tide), September 18, 1875; 5½ miles in the sea at Brighton, Miss Dick, 2 h. 43 m., September 9, 1875; 5 miles, C. Whyte, 1 h. 4 m. 23 s., in Thames (with tide), July 18, 1870; 5 miles, Miss Lizzie Gillespie, 1 h. 20 m. 7 s., in river Tay, Dundee (with tide), August 1880; 2 miles, E. T. Jones, 25 m. 22⅘ s., in Thames, September 10, 1877; 2000 yards, J. B. Johnson, 34 m. 30 s., in Serpentine Lake, August 1873; 1 mile, E. T. Jones, 25 m. 22¾ s., in Thames, September 10, 1877. The difference between swimming in open water and in a bath is exceedingly great, on account not only of the lower temperature of the former, but also because of the advantage turning and pushing off at each end of the bath gives the swimmer. In Hollingworth Lake on August 23, 1884, J. J. Collier swam a mile in 28 m. 19¾ s.; at Lambeth Baths (40 yards long) the same swimmer, on October 23, 1885, did the distance in 27 m. 3½ s. Again, it took Collier 15 m. 44 s. to swim 1000 yards in Hollingworth Lake; while at Lambeth Baths, Westminster, the distance was, on October 16, 1890, swum by J. Nuttall in 13 m. 54½ s. The difference in the times for half a mile is comparatively greater; but this may not be so real as the figures indicate. On 16th July 1898 J. A. Jarvis won the mile amateur championship in 26 m. 37⅕ s. Jarvis also won the amateur half-mile championship (1898) at Leicester in the record time of 12 m. 52 s. The same swimmer won the quarter-mile salt-water championship (1898) at Weymouth in 6 m. 32 s. A quarter of a mile was swum by J. Finney in Blackpool Bath in 5 m. 57 s.; at Lambeth Nuttall swam 400 yards in 5 m. 16½ s. At Manchester on July 6, 1898, J. H. Derbyshire, amateur, won the national 100-yards championship in the record time of 60⅘ s., the previous world's record being that of J. H. Tyers—61⅖ s.

Until April 7, 1886, a much disputed question was the length of time a person could remain under water. On the date given J. Finney, in a tank at the Canterbury Theatre of Varieties, London, remained below the surface 4 m. 29¼ s., which time will probably never be equalled, the nearest approach to it being 3 m. 18¼ s. on September 27, 1889, by Miss Annie Johnson. Finney also has swum 113 yards 1 foot in costume under water. This he did on October 20, 1882, at Blackpool, in a bath 28 yards 1 foot long. The best plunge or standing dive, the body, which has to be kept face downwards, having no progressive action imparted to it other than the impetus of the dive, stands to the credit of W. Alleson, amateur, who on 7th October 1896, at Lewisham, did 80 ft. 8½ in. Among other remarkable performances may be mentioned those of T. Burns, who dived from Runcorn Bridge (85 feet) in October 1889, and then swam to Liverpool, from whence he walked to London and dived off London Bridge; and J. Finney, who, at Manchester on April 30, 1890, with his mouth picked up seventy-five coins from the bottom of a tank, his hands being tied behind his back.

See Wilson's *Swimming Instructor* (1883), Cobbett's *Swimming* (1889), and the Badminton book by Sinclair and Henry (1893; 3d ed. 1900); also CRAMP, RESPIRATION (ARTIFICIAL), DROWNING, and HUMANE SOCIETY.

Swinburne, ALGERNON CHARLES, was born in London on April 5, 1837, but belongs to a Northumbrian family, being the son of Admiral Swinburne and of Lady Jane Henrietta, the daughter of the Earl of Ashburnham. He was educated at Eton and at Balliol College, Oxford, which he entered in 1857 and which he left without taking a degree. He then spent some time in travelling on the Continent, and in 1864 he visited Walter Savage Landor at Florence. On his return to England he became closely associated with Dante Rossetti and William Morris, and his life has thenceforth been that of a man of letters and has been mainly spent in London. His first book, a tragedy entitled *The Queen Mother and Rosamund*, was published in 1861, but did not excite much attention. It was otherwise with *Atalanta in Calydon*, which appeared in 1864, and proved that a new singer with an exquisite lyrical gift had arisen. Mr Swinburne has produced no poem of similar length so full of beauties as *Atalanta;* and there are some, and these, perhaps, not the least competent judges of his verse, by whom this drama is even now more dearly prized than any other of its author's works. The tragedy of *Chastelard* was deservedly far less successful, and in 1866 the first series of *Poems and Ballads* awakened a storm of adverse criticism. The outcry was in the main unjust; but one or two of the pieces had better not have been written, and the language of others was now and then such as to give a colour of plausibility to the strictures passed on the book. The finest pieces, *Hesperia*, *Itylus*, *A Match*, *The Garden of Proserpine*, the *Hymn to Proserpine*, *The Triumph of Time*—these, to name but these, were a revelation to students of English verse. The writer struck a note which none had struck before. You might object, and now and then rightly object, to the erotic tone of certain passages, but there was no resisting the lyric fire and the consummate artistry, the magnificencé of the rhythm, the new, strange sweetness of the music. *A Song of Italy* appeared in 1867 and an *Ode on the Proclamation of the French Republic* in 1871. By the publication in the latter year of *Songs before Sunrise* Mr Swinburne was again exposed to censure, extravagant in part and in part not unmerited. There is much admirable verse—fiery and ringing and technically perfect—in the volume; it contains, however, no such fascinating masterpieces of lyric art as the best of the *Poems and Ballads*, and to most readers the political opinions held by Mr Swinburne at the time of its composition will appear to be visionary and crude, and to be often intemperately urged. In 1871 Mr Robert Buchanan attacked Dante Rossetti and Mr Swinburne on the score of the alleged immoral tendency of their verse; the accuser's pamphlet, *The Fleshly School*, drawing forth a counter pamphlet, *Under the Microscope*, from Mr Swinburne. *Bothwell*, a long chronicle play, without any attempt at theatric structure, in which historic truth, so far as understood by the poet, was made the primary quest, appeared in 1874; *Erechtheus*, a noble lyric drama, extremely unlike *Atalanta*, inasmuch as it was written with great exactitude (even as to the number of its verses) upon the lines of a Greek drama, in 1875; and a second series of *Poems and Ballads* in 1878. Since then their author has issued *Songs of the Springtides; Songs of Two Nations; Studies in Song; A Century of Roundels; Marino Faliero; Locrine*, a rhymed tragedy; *Tristram of Lyonesse*, a fine narrative poem in decasyllabic couplets; *Mary Stuart*, a play completing the trilogy begun in *Chastelard* and continued in *Bothwell;* and a third series of *Poems and Ballads*, containing the superb sea-and-battle piece, *The Armada*, in 1887. *The Sisters*, a short tragedy of modern life, published in 1892, was less favourably received than any of his previous works. Mr Swinburne's prose works include two volumes of critical essays (on Byron, Shelley, Coleridge, Rossetti, Tennyson, Musset, &c.), and separate studies of William Blake, George Chapman, Ben Jonson, Charlotte Brontë, Hugo, and Shakespeare. He has one pre-eminent excellence as a critic, the faculty of discerning and giving the most generous recognition to literary merit in its most dissimilar forms—in Congreve as in Wordsworth,

in Pope as in Webster, in Anthony Trollope as in Cyril Tourneur. The genius of Victor Hugo, however, has been unto him even as a siren, his idolatry of the great romanticist not only finding expression in immoderate eulogy, but prompting him now and then to belittle the works of other poets—most notably those of Alfred de Musset. The merits and defects of his prose style were at first almost equally striking. He abused his magnificent command of epithet, he was super-emphatic, and he frequently employed figures which are only admissible in verse. These defects are much less conspicuous in his later essays, and in his finest passages it would be hard to excel the splendid glow and ornate grace of the diction and the stately mould of the sentences.

Mr Swinburne is the greatest metrical inventor in English literature. Other poets have equalled him in melody, but none other has revealed the tunefulness and pliancy, the majesty and grace of the English speech in such a variety of lyrical forms. He can impart dignity and distinction to the simplest measures, and move with faultless ease in the most elaborate. He can take a thing like the roundel, a form which seemed to be only adapted for ingenious trifling, and render it a sonorous instrument for brooding thought or impassioned imagination. He can give rapid and graceful movement to heavy-laden, long-drawn metres which other artists in verse would find unworkably cumbrous. He can stir the blood by the rush and resonance of a battle-chorus, or charm the ear by the music of a love-lyric as sweet as the songs of spring. His music is like no other man's, and whether the verses are running lightly, marching proudly, or swinging impetuously, the music is alike irresistible. He has been accused of tautology and obscurity, and even of drowning sense in sound. He has no doubt a tendency to use redundant phrases and unfamiliar inversions, and to carry alliteration to excess. But the charge of obscurity has been generally urged in ignorance of his aims and from misappreciation of his craftsmanship. With the possible exception of Gérard de Nerval, he is the modern poet whose aims and methods approach most closely to the musician's. Vague Mr Swinburne sometimes is; but he is so most often of artistic intent. Words which may at first seem pleonastic and even meaningless are discovered on further reading to have been inserted with delicate art to deepen the impression of mystery or beauty which the writer sought to suggest by the verbal music of a given passage. In dealing with nature his endeavour is not to produce a minute transcript, but to render the spirit of a scene, to catch and convey the elusive haunting secret of its loveliness or its terror. *The Garden of Cymodoce* admirably illustrates his descriptive method. You feel at first as if the meaning of certain phrases were escaping you; but as you read, the charm, at once daunting and seductive, of the wonderful sea-hall—the magic of the lovely crimson glimmer and of the gloom which seems to dilate above the black silent water—is borne in upon you by the suggestion of the music, the subtle verbal colouring and shading, the premeditated vagueness of certain lines, as it could never have been by any number of direct and minute descriptive touches. The poem is as perfect in one way as Keats's *Hymn to Pan* is in another. Of all our poets Mr Swinburne is the poet of the sea. He knows the ocean in all its moods; he has rendered with equal perfection the revel of storming surges, the magnificent rolling of deep-sea billows, the soft glow of the bowers of the water-world, the sensuous delight of a swimmer swimming out as the morning breaks over the green rippling deep. His versatility has not yet gained due recognition. He has dealt with the most various subjects and drunk inspiration from the most various sources; he has worked as a lyric, a narrative, and a dramatic poet; in style he has ranged from the most ornate manner to the most austere. None of his later volumes can awaken the delight with which his readers greeted the outburst of soaring song and lyric fire in *Atalanta*. The joy of that surprise can never be renewed. And in splendour of rhythm, in witchery of phrase, in passionate imaginative glow the last series does not and could not well surpass the first series of *Poems and Ballads*. But in nobility of aspiration, width of sympathy, and bracing love of nature the advance is indubitable. In the early poems (saving *Atalanta*) the air was too often as that of a hothouse; it was enervating to linger in the society of Felice and Yolande and Juliette. But the old languor and pessimism have passed away; the mournful amorist of the *First Series*, the indignant rebel of *Songs before Sunrise*, has become the exultant singer of the sea and the sea-wind, the high-hearted lyrist of the great deeds and imperial destiny of England. In the early poems we were transported to the clear-cut, clear-coloured hills of Greece and the drowsy garden-closes of the south; in the latest we hear the night-wind rushing over the 'mirk muir sides' of the Scottish Border and the Tyne roaring in spate. Mr Swinburne's plays, setting aside *Atalanta*, are of far inferior importance to his lyrics, though they contain noble passages of poetry, and though in his Mary Stuart he has achieved a triumph of dramatic creation.

Recent works are *Astrophel* (1894), *Studies in Prose and Poetry* (1894), and a *Tale of Balen* (1896). There are bibliographies by Shepherd (1887) and Wise.

Swindling. See FRAUD.

Swindon, a town of Wiltshire, 77 miles W. of London and 29 ENE. of Bath, consists of Old Swindon (*Svindune* in Domesday), on an eminence 1¼ mile S., and New Swindon, which originated in the transference hither in 1841 from Wootton-Bassett of the engineering works of the Great Western Railway. The former is rather a picturesque place, with a good Decorated parish church (rebuilt by Sir G. G. Scott in 1851), a town-hall (1852), assembly rooms (1850), and a corn exchange (1867); New Swindon has a mechanics' institute (1843), a theatre, &c. Pop. (1861) 6856; (1881) 22,374; (1891) 32,840 (5545 in Old Swindon).

See J. E. Jackson's *Swindon and its Neighbourhood* (1861), and the *English Ill. Mag.* for April 1892.

Swine. See PIG.

Swinemünde, a fortified seaport of Prussia, on Usedom Island, at the entrance of the narrow channel of Swine, connecting the Grosses Haff (into which the Oder flows) with the Baltic. It is yearly entered by nearly 500 vessels of 229,000 tons burden (one-third British), and has valuable fisheries and excellent sea-bathing. Pop. 8626.

Swing, a cognomen assumed by senders of threatening letters during the period when the irritation of the agricultural labourers of England against their employers was at its height, namely from 1830 to 1833. The cause of this misunderstanding arose from a wide-spread belief on the part of the labourers that the use of machinery would greatly lessen the demand for labour, and consequently produce a general reduction of wages; it was also intensified by the savage severity with which the game-laws were enforced, and by other hardships to which the labouring classes in the country considered themselves unjustly subjected. As disregard by landlords or farmers of the demands contained in these threatening letters was constantly followed by the burning of stacks and farm-buildings, the employers of labour became so

terrified that in very many cases almost implicit obedience was paid to the dictates of 'Captain Swing.'

Swinton, (1) a town in the West Riding of Yorkshire, 5 miles NNE. of Rotherham. It has manufactures of bottles, iron, pottery, &c. Pop. (1891) 9697.—(2) A town of Lancashire, 4½ miles WNW. of Manchester, with cotton-mills and brick-fields. Pop. of Swinton and Pendlebury urban sanitary district (1871) 14,052; (1891) 20,197.

Swiss Guards, a celebrated corps or regiment of Swiss mercenaries in the French army of the old régime, constituted 'Gardes' by royal decree in 1616. Mercenaries as they were, they were ever unswerving in their fidelity to the Bourbon kings, and their courage never blazed more brightly than on the steps of the Tuileries, 10th August 1792. They had been ordered to leave Paris by a decree of the Assembly on July 17th, but had not yet been sent farther than their barracks, when on August 8th, in anticipation of insurrection, they were ordered to march to the Tuileries. Michelet gives their number as 1330; Challamel, Pollio, and Marcel in *Le Bataillon du Dix Août* (1881) as 1200; Louis Blanc as 950; Mortimer-Ternaux as 900 to 950. But the number may now be taken definitely as nearly 800, including the ordinary guard of the king (see Captain de Durler's MS. *Relation* printed by Mr H. Morse Stephens in *Eng. Hist. Review* for April 1887). In anticipation of a storm Mandat had made admirable arrangements to defend the palace, but the National Guards fraternised with the insurgents, and Mandat himself was murdered on the steps of the Hôtel de Ville, whither he had gone by the king's command on a summons from the municipality. Meanwhile a growing mob under Santerre, with the famous 500 men of Marseilles at their head, marched on the Tuileries. But before they reached the palace Roederer had persuaded the king to leave the Tuileries and place himself and the royal family under the protection of the National Assembly. He was accompanied thither by 150 Swiss, besides two hundred gentlemen and about a hundred National Guards. The remainder were left without orders, uncertain what to do, and when Westermann with his Marseillais and a raging mob made their way through the gate of the Tuileries and across the court the 650 Swiss under Captain Durler faced them on the great staircase, knowing only the orders of the night before that they were not to suffer themselves to be forced. Westermann, an Alsatian, tried to win them over by speaking to them in German, but it was not so that these men had learned duty. Some one fired a shot, and the struggle began. The Swiss had already driven back Westermann with about a hundred dead, when the king hearing the firing sent them orders to leave the palace. They fought their retreat across the gardens, while the mob swarmed into the palace and murdered a few wounded men they found there. Those under Durler made their way to the Assembly, were disarmed and placed in the neighbouring church of the Feuillants; but those who were posted in the corridors and rooms of the palace did not hear the order to retreat, and were speedily attacked, overpowered by the mob, and hunted to death. A few fought their way out across the gardens only to find the drawbridge up, whereupon they made for the Place Louis XV., formed a square under the statue of the king, and were cut to pieces where they stood. Few but those who found refuge in the church of the Feuillants survived that fatal day. Fifty-four were sent to the Abbaye and were among the first to perish in the atrocious September massacres. The heroism of the Swiss Guards was fittingly commemorated in 1821 by the great lion outside one of the gates of Lucerne, cut out of the rock after a model by Thorwaldsen.

See Pfyffer d'Altishofen's *Récit de la Conduite des Gardes Suisses* (Lucerne, 1824); Durler's *Relation* already quoted; vol. ii. (1891) of H. Morse Stephens' *History of the French Revolution;* also the article MERCENARIES.

Switchback, a term applied to a zigzagging, alternate back and forward mode of progression up a slope. A 'switchback railway' originally meant one where the ascent is up a steep incline simplified by curving the track backwards and forwards (and upwards) on the face of the slope. Afterwards the term came to be applied to a railway where (as at Mauch Chunk, q.v.) the movement of the carriages is largely effected by their own weight alone, the descents by gravity and the ascents by a stationary engine. (This railway, once used for carrying coal, was superseded in this capacity by a tunnel, and subsequently reserved for pleasure excursions.) Hence the application to the well-known apparatus for amusing the public at watering-places, fairs, and exhibitions: a short length of elevated railway with a series of rounded inclines, so that the car gains enough of momentum descending the first steep incline to ascend one or more smaller inclines till it gradually and more slowly works its way to the original level at the far end of the course. Thence it returns in the same way. Sometimes these switchbacks are made circular. Very similar were the so-called *Montagnes Russes,* elevated wooden frames with (wheeled) cars rushing down and up the slopes again, designed to represent Russian snow-slides, which were introduced into Paris as a popular amusement about 1815. The 'Flying Mountains' of St Petersburg had been described by Lord Baltimore in his *Gaudia Poetica* (1770). Thomas Moore's *Epicurean,* published in 1827, and based on some knowledge of the Montagnes Russes, describes very nearly the modern switchback.

Swithin, or SWITHUN, ST, Bishop of Winchester from 852 to 862. The 11th century Life attributed to Gotzelin may contain elements of historical truth, and according to it he was tutor to Egbert's son Ethelwulf, under whom he was made bishop. He was a devoted builder of churches, and a man of unusual piety and humility. He built a bridge at the east side of the city, and here he used to sit and watch his workmen. One day some of them broke an old woman's basket of eggs, whereupon the bishop miraculously restored them. He died in 862 and was buried in the churchyard of Winchester, having asked, says William of Malmesbury, to be laid where 'passers by might tread on his grave, and where the rain from the eaves might fall on it.' A century later he was canonised, and the monks exhumed his body to deposit it in the cathedral; but this translation, which was to have taken place on the 15th July, is said, though unfortunately not by contemporary chroniclers, to have been delayed in consequence of violent rains. Hence the still current belief that if rain fall on the 15th July it will continue to rain for forty days. Unhappily Professor Earle has exploded the ingenious legend about the saint's displeasure, and shown that a much more probable origin is to be found in some primeval pagan belief regarding the meteorologically prophetic character of some day about the same period of the year as St Swithin's. In France the watery saints' days are those of St Médard (8th June), and St Gervais and St Protais (19th June). The rainy saint in Flanders is St Godelieve (6th July), and in Germany among the saints' days to which this belief attaches is that of the Seven Sleepers (27th June).

SWITZERLAND

Switzerland. The republic of Switzerland is a confederation of twenty-two cantons, three being divided into half-cantons, situated in the centre of Europe between France, Germany, Austria, and Italy. The greatest length from east to west is 216 miles, the width from north to south being 137 miles; area, 15,981 sq. m. The population in 1850 was 2,392,740; in 1895, 2,986,848. The following table (arranged in alphabetical order) gives the results of the census of 1888. The ordinary name is put first, followed by the French name in the German cantons, and by the German in the French ones. F. or G. or F.G. indicates that the majority speak French, or German, or both. When neither P. nor R.C. is appended, it is to be understood that the canton is partly Protestant and partly Catholic.

Surface.—The area of Switzerland (15,981 sq. m., of which 11,443 are classed as 'productive' and 4538 as 'unproductive') is distributed over four river-basins—those of the Rhine, the Rhone, the Inn, and the Ticino, a tributary of the Po. The Confederation is bounded on the S. by a part of the main chain of the Eastern Alps, running from south-west to north-east, on the W. and NW. by the Jura, and on the N. by the Rhine. The Pennine Chain of the Alps lies to the south of the valley of the Rhone, on the north of which valley are the Bernese Alps extending from the Lake of Geneva to the Grimsel. East of the Bernese Alps is the St Gothard group, with its ramifications in the direction of Lucerne and Glarus. The Rhætian Alps are east of the Pennine Chain. A broad fertile plain extends from the Lake of Geneva to the Lake of Constance. The lowest level on Swiss territory is 646 feet on the banks of Lake Lugano; the highest is 15,217, the summit of Monte Rosa. Of the 4538 sq. m. of land classed as 'unproductive' 3229 are covered by rocks, moraine, &c., 711 by glaciers, 535 by lakes, and 63 by towns and villages. The largest lakes in Switzerland are those of Geneva and Constance; there are fifteen which cover an area of over 3 sq. m. each. There are numerous waterfalls, the highest (1002 feet) being the Staubbach in the Bernese Oberland. The Falls of the Rhine at Schaffhausen are upwards of 80 feet in height, and have been called a 'miniature Niagara.' There are about 470 glaciers, the largest being the Gross Aletsch, 15 miles in length. In Valais a greater surface is covered by glaciers than in any other canton; there are, however, no glaciers in eleven cantons. In the Central Alps the limit of perpetual snow varies from 9250 to 9020 feet.

Geology.—The geological structure, assisted by denudation, gives the country its picturesque character. In the south the chain of the Western and Central Alps consists of a series of crystalline masses lying south-west and north-east, covered on the northern slope by sedimentary rocks belonging to the Triassic, Jurassic, and Cretaceous formations. These coverings of sedimentary rocks are much folded, and overlap, forming limestone cliffs (Wetterhorn, Eiger, Jungfrau, &c.). To the north is the Jura range, a chain of regularly folded and anticlinal hills with longitudinal valleys often intersected by ravines. The wide plateau between the Jura and the Alps consists of tertiary deposits of sandstone and clay, partly lake and sea deposits; it is covered also by deposits of ancient glacier-moraines and gravels of the last glacial epoch. Few metallic deposits are to be found in Switzerland; those which exist cannot be worked owing to the irregularity of the veins. In Valais there are coal-formations metamorphosed into crystalline rocks, the coal being changed into anthracite of very irregular size. Salt is obtained in the valley of the Rhine at Rheinfelden. See ALPS, JURA, &c.

Climate.—In a country where the height above the sea-level is from 646 feet—where the almond, the fig, and the olive ripen in the open air—to 15,217, the region of perpetual snow, there is great variety in the climate. There is a variation of about 34½° in the mean temperature; at Bellinzona it is 54½° F.; at Geneva, 49½°; Interlaken, 48¼°; at the Hospice on the Great St Bernard it falls to 30°, and on the Theodule Pass to 20°.

Language.—The population is composed of four distinct ethnical elements. The language of 71·3 per cent. of the population (2,092,479) is German; of 21·8 (637,710), French; of 5·3 (156,482), Italian; of 1·6 (46,941), Romansch or Ladin.

Religion.—By the federal constitution liberty of conscience and belief is declared to be inviolable, and the free exercise of worship is guaranteed within the limits compatible with public order and decency. No bishopric can be established in Switzerland without the consent of the Confederation. There is no federal church, each canton has its own ecclesiastical constitution and organisation, and the majority of the citizens can dispose of the church funds (derived from a variety of sources) belonging to each canton. By the census of 1888, 1,724,869 (58·8 per cent.) are Protestants, 1,189,662 (40·5) are Catholics, 8384 (0·3) are Jews, and 10,697 (0·4) belong to other confessions.

Constitution and Government.—The republic of Switzerland became a federal state (*Bundestaat*) in 1848: previously it consisted of a league of semi-independent states or cantons. The present constitution, based on laws passed in 1848 and revised in 1874, was constructed with the view of satisfying both cantonal and national elements, and is therefore essentially a work of compromise. It is the first constitution which was entirely the work of the Swiss without foreign influence, although its authors studied that of the United States. The political structure of Switzerland is built up in three tiers—the Commune, the Canton, and the Federal Assembly. In the communes all local matters are administered by two governing bodies—the Communal Assembly (which is purely legislative), composed of all male citizens who have attained the age of twenty, and the Communal Council, the executive of the former body, by whom it is elected. Each canton has its own constitution and local government. The constitutions of the several cantons vary considerably, but

all are based on the principle of the absolute sovereignty of the people, subject to certain restrictions chiefly regarding military and legal matters imposed by the federal constitution: they are subject also to the ratification of the Confederation. In Uri, the two half-cantons of Appenzell, and in Glarus there still exists the ancient *Landsgemeinde*, an open-air gathering of all those possessing votes, who meet every spring to legislate on cantonal affairs. These cantons possess a representative power in their *Landrath*, and an executive power in the *Regierungsrath*. In other cantons the citizens elect representatives to the cantonal council from electoral districts. The citizen of a commune is *ipso facto* citizen of the canton in which his commune is situated, and therefore votes in the election of the cantonal council. In the majority of cantons this body choose from among their own number an executive, who superintend all cantonal affairs and the government of the communes; the members also transact business with the federal government and with that of other cantons. The supreme legislative authority of the Confederation is vested in a parliament of two chambers, the Council of the States (*Ständerath*) and the National Council (*Nationalrath*), which represent the supreme government of the country, under reserve of the *referendum* or vote of the people. The Council of the States consists of forty-four members, each canton having two representatives, and each half-canton one. The regulations as to their election and duration of term of office differ in each canton. The National Council consists of 147 members, elected in each canton in the proportion of one deputy for every 20,000 of the population. The electoral districts cannot be made up of parts of different cantons, and are fixed by the Federal Assembly after every census; the election takes place once every three years. Every male who has attained the age of twenty and possesses the rights of citizenship according to the constitution of his canton, is entitled to vote, and any voter other than a clergyman or an official appointed by the Federal Council is eligible for election as a representative. The sum of 16s. a day is paid during session to the members of the Council of the States and the National Council. These two chambers each elect a president and vice-president, and meet at Berne at least twice a year in June and December, together forming the Federal Assembly. This body controls the general administration of the Confederation; they alone can declare war, make peace, or conclude treaties with foreign powers. The executive authority of the Federal Assembly is deputed to the Federal Council composed of seven members, elected for a period of three years and each receiving a salary of £480 per annum, except the president, who receives £540. No canton can have more than one citizen in this council; its duties are divided among seven departments, one member being charged with the direction of each. The president of the Federal Council, who is also president of the Confederation, is chosen annually at a united meeting of the Council of the States and the National Council from among the members of the Federal Council. The president and the vice-president (who is chosen at the same time) are elected for one year, and cannot be re-elected within twelve months of the expiration of their term of office.

Referendum and Initiative.—These are two political institutions peculiar to Switzerland, the furthest developments of democracy yet attained. In 1831 an article was introduced into the constitution of St Gall, declaring 'the sovereignty of the people, who have the right not only to pass their own laws, but also to veto them.' This paved the way for the *referendum*, which has now spread throughout the whole Confederation, and by means of which all legislative acts passed in the Federal or Cantonal Assemblies may be referred to the people *en masse*. It is of two kinds, compulsory and optional, both as regards federal and cantonal matters. In those cantons where all laws adopted by the representative body of the canton must be submitted to the people it is compulsory; in those cantons where it may be demanded by a certain number of votes it is optional. With the exception of Freiburg, cantonal *referendum* exists in those cantons where there is no *Landsgemeinde*. In the majority of cantons 5000 signatures are required in order to obtain a *referendum* for cantonal laws. The compulsory *referendum* regarding federal legislation was established in 1848, but was then limited to the revision of the constitution. That of 1874 contains an article extending the exercise of the popular vote, when demanded by 30,000 citizens or eight cantons, to all laws and resolutions of a general nature passed by the Federal Assembly, this being the optional form of the federal *referendum*. Since the *referendum* was fully developed in 1874 it has been put in operation on an average once a year; the decisions have generally shown a conservative rather than a radical tendency on the part of the people.

Initiative is the exercise of the right granted to voters to initiate proposals for the enactment of new laws or for the alteration or abolition of old ones. By this means the 'sovereign people' have always the power to bring forward the discussion of legislative matters, even in the event of their representatives in the government being unwilling to do so. Fifty thousand signatures are required to obtain the initiative regarding federal legislation, and in the majority of cantons 5000 for cantonal matters.

Law and Justice.—With the exception of the Federal Bankruptcy Act, applicable throughout the whole of the Confederation, the procedure in civil and criminal matters varies in the different cantons. In the French cantons, with the exception of Geneva, the civil codes are based upon the *Code Napoléon*, while in the German cantons they differ considerably from each other, and are for the most part original. In Uri and Appenzell there exists not only a code, but customary laws, to which the court gives effect. In ten cantons representing twenty per cent. of the entire population capital punishment exists. By the federal constitution, 'no sentence of death can be pronounced for a political offence.'

Revenue and Expenditure.—The revenue is derived chiefly from the postal and telegraph services, the customs, powder manufactories, the tax for exemption from military service, and from the real property of the Confederation, the federal government having no power to levy direct taxes, as the separate cantons have. The budget of 1898 estimated the revenue at £3,635,000, and the expenditure at £3,573,600. Customs produce £1,840,000. The public debt in 1898 amounted to £3,355,665, but the state property, including railways, was valued at £7,522,528, leaving a large credit balance. The government agreed to subscribe £600,000 (by contributions from the cantons) towards the cost of the Simplon Tunnel (q.v.), to be finished in 1994. The proceeds of the federal alcohol monopoly, about £255,000 annually, are divided among the cantons. Each canton has its own budget of revenue and expenditure and debts. The combined debts of the cantons amount to about £10,000,000, which is covered by cantonal property, mostly in land.

Army.—The federal constitution forbids the maintenance of a standing army; still, it declares

that 'every Swiss is liable to military service.' The army is therefore essentially a citizen force drawn from all classes of the people, being intended only for defensive purposes and to secure the neutrality of the country. It is divided into three classes—the *Élite* or active army, in which all citizens are liable to serve from the age of twenty to thirty-two; the *Landwehr*, from thirty-two to forty-four; and the *Landsturm*, consisting of men from seventeen to fifty not incorporated in the two former classes. Every Swiss keeps his rifle and kit, and in the case of a cavalry soldier his horse, at his own home. Cavalry recruits provide their own horses, which they may use for agricultural or other purposes during the remainder of the year; one-tenth of the price is refunded annually by government. The total strength of the army, not including the *Landsturm*, is: *Élite*, 125,620; *Landwehr*, 80,715; total, 206,335. With the exception of the heads of the ordnance departments, the General Staff and the Corps of Instructors—about 200 in number—are the only officers permanently paid and employed.

Education.—Primary instruction is compulsory, unsectarian, and is provided gratuitously at the cost of each canton, whose officials control the administration and inspection of the schools; thus the details of organisation vary considerably in the different cantons. The period of compulsory attendance is usually from the age of five or six up to fourteen, fifteen, and even sixteen. In many cantons those children who do not enter the secondary schools must pass into the supplementary ones, which generally meet twice a week, the aim of the teachers being to help the scholars to retain what they have learned in the primary schools. There are five universities on the German model —Basel, Bern, Zurich, Geneva, Lausanne, and (for Catholics only) Freiburg; there is also an academy at Neuchâtel, which does not, however, possess the four faculties. The Polytechnic at Zurich is a technical college under the control of the federal authorities, attended by 900 students, the annual cost of maintenance being £20,000. The most important technical schools are the Technikum at Winterthur, those of silk-weaving at Zurich, watchmaking at Geneva, La Chaux de Fonds, Neuchâtel, &c., and wood-carving at Meyringen. Practical as well as theoretical instruction in agriculture is given in the farm-schools at Strickhof and Rütte, and during the winter months short courses of lectures are given gratuitously in the rural districts on horticulture, vine-growing, cattle-breeding, &c.

Agriculture, &c.—All the land in the Confederation is freehold, the cost of transfer in each canton being extremely moderate. More than one-half of the arable land is devoted to cereals; still in 1889 flour to the value of £3,907,550 was imported. Cattle-breeding is an industry of great importance. The Swiss possess two excellent breeds, the parti-coloured and the brown. The former are amongst the heaviest in Europe, the milk being admirably adapted for making cheese and butter. The brown race is a medium-sized breed, its headquarters in Schwyz, Lucerne, and Zurich. There are upwards of 5500 cheesemaking establishments, and the following are the exports in connection with this industry: cheese, worth £1,561,191, to France, Italy, Germany; condensed milk (£438,071) to Great Britain; and butter (£50,742) to France. Tobacco is grown chiefly in the cantons of Valais, Vaud, Freiburg, Bern, and Aargau; the quality is by no means good, but the exports (including cigars and cigarettes) amount to £90,000 a year. The vine flourishes best on the slopes surrounding the lakes of Geneva, Neuchâtel, Biel, and Zurich. The average annual production of wine amounts to 31,266,400 gallons; but about 15,400,000 gallons are annually imported, exceeding the exports by 11,000,000.

Commerce.—Little or no coal is to be found in the Confederation, there are no canals or navigable rivers, the country is situated far from the seacoast, and nearly the whole of the raw material and half-finished goods have to be imported. Still, in spite not only of these drawbacks but of the protective policy adopted by the neighbouring powers, there is a larger general trade per head of the population than in almost any other European country, amounting to over £13 for imports and £9, 13s. for exports. In 1895 the imports amounted to £39,204,600, and the exports to £28,177,000; while if we include the transit trade the totals are over £60,000,000 for imports and over £50,000,000 for exports. The trade for 1890 with the principal countries was:

	Imports	Exports.
Germany	£10,800,075	£7,384,249
France	10,492,092	5,691,241
Italy	5,632,130	2,057,434
Austria-Hungary	4,259,629	1,541,362
Great Britain	2,031,239	4,238,003

The textile industries are the most important, the chief centres being Zurich, Basel, Glarus, and St Gall, the total value of the goods exported being in 1897, £12,484,400, including silk, cotton, and linen fabrics, besides raw silk to the value of £1,468,000. Next comes the watchmaking industry, established at Geneva in 1587, which spread to the cantons of Neuchâtel, Bern, and Vaud. The annual value of the watches, &c., exported in 1895–98 amounted to £4,120,000, machinery to £1,360,000, and cheese to £1,520,000. Wood-carving, introduced in the Oberland about 1820, employs 4000 persons. In 1899 there were 2500 miles of railway. The gross amount of money brought annually by tourists into the 'Play-ground of Europe' is estimated at £4,000,000.

History.—The occupants of the Lake-dwellings (q.v.) were the first inhabitants known to us. At the time of the Roman invasion the two principal tribes in possession of the country were the Celtic Helvetii and the Rhætii (of doubtful affinities). In 58 B.C. the Helvetii were partially subdued by Julius Cæsar, but it was not till 15 B.C. that they were completely subjugated by Augustus. These became part of the Roman empire, and during the three following centuries trade was developed and military roads were constructed, e.g. the St Gothard, the Great St Bernard, and that crossing the Julier. The chief Roman settlements were *Aventicum* (Avenches), *Augusta Rauracorum* (Kaiser Augst) and *Vindonissa* (Königsfelden). After the conquest of Gaul Helvetia was invaded by the Burgundians and the Alemanni 450 A.D. The former took possession of western Switzerland, and the latter settled east of the Aar, in the district since known as 'La Suisse Romande.' In the 7th century, during the domination of the Frank kings of the Merovingian dynasty, order was restored, and Christianity preached by SS. Gallus, Columbanus, and others. About this period the great monasteries of Einsiedeln, Dissentis, St Gall, and Pfäffers were founded, which soon became centres of progress and learning. Much of what later became Switzerland then formed part of the Holy Roman Empire, for which it was ruled by wealthy abbots and nobles, among whom were the Counts of Zähringen. This powerful family became extinct in 1218, and the country was distracted by internal wars. In 1273 Rudolph of Hapsburg (whose castle was situated in what is now the canton of Aargau) was raised to the imperial throne; after his death (1291) a short period of anarchy ensued in the empire. The inhabitants of Uri,

Schwyz, and Unterwalden then felt the necessity of joining together in order to defend their common interests. The Confederates (*Eidgenossen*) did not, however, throw off their allegiance to the emperor; their hostility was rather directed against the despotic power exercised by the bailiffs or middlemen, some of whose acts of tyranny have been described in Schiller's *Wilhelm Tell*, which is founded on the legends belonging to that period (see TELL). Out of this defensive alliance sprang that pact which constituted the germ of the present Swiss Confederation, but which from 1291 to 1874 has passed through seven distinct phases—viz.: (1) The League of the Three Communities, 1291: (2) The Confederation of eight cantons, 1353; (3) The Confederation of thirteen cantons, 1513; (4) The Helvetic Republic, 1798; (5) The Act of Mediation, with nineteen cantons, 1803; (6) The Federal Pact, with twenty-two cantons, 1815; (7) The Federal Constitution of 1848, revised in 1874.

In 1307 it is stated that Werner Stauffacher of Schwyz, Walter Furst of Uri, and Arnold of the Melchthal in Unterwalden (representatives of the three leagued cantons) met together in the meadow of Grütli by the Lake of Lucerne, and took an oath to free their soil from the Austrian oppressors. They swore that they would be 'all for each, and each for all,' which still remains the motto of the Confederation. Five years later the Confederates were called upon to vindicate this oath, and defend their country against Leopold of Austria. In 1315, while marching at the head of a powerful army through a defile beneath the heights of Morgarten, he was surprised by the Swiss, who hurled down stones and trunks of trees, completely routing their opponents. In 1332 Lucerne joined the alliance of the Three Communities, and the League was increased to four Forest States or Cantons (*Vierwaldstätten*). Bern and Zurich had become imperial fiefs, and the growing importance of the former excited jealousy in western Switzerland, with the result that in 1339 a large force laid siege to Laupen, but were defeated by the Bernese under Rudolph von Erlach. By 1353 Bern, Zurich, Glarus, and Zug joined the Confederation, which thus attained its second phase of eight cantons. The Austrians were again routed at Sempach in 1386, and in 1388 at Näfels; and subsequently in 1393, with the view of strengthening the federal sovereignty, the confederates drew up the document known as the 'Convention of Sempach.' The Swiss were next engaged in a struggle on the French frontier with Charles the Bold; they defeated him at Grandson in 1476, again at Morat, and finally in 1477 before the walls of Nancy, where Charles himself was slain. The unequal distribution of the booty taken at Grandson and Morat occasioned much jealousy between the five rural states or cantons and the cities of Zurich, Bern, and Lucerne; the dissolution of the Confederation seemed imminent, but owing to the intervention of Nicholas von der Flüe an understanding was effected at the Diet of Stanz in 1481, laws were made as to the admission of new cantons, and separate alliances between them were prohibited. By 1513 Freiburg, Solothurn, Basel, Schaffhausen, and Appenzell were added to the Confederation, this being the third phase of its history. In addition to these were associated and protected states, as well as subject territories, belonging to one or other of the various cantons. Valais, the Grisons, Geneva, Biel, and Mühlhausen were republics. The principality of Neuchâtel, the lands of the Abbey of St Gall, and the bishopric of Basel were ruled by lay or ecclesiastical sovereigns.

The 16th century saw the rise of Protestantism. Zwingli led the van in Zurich, whence the Reformation spread, first to Bern and then northwards; the Forest Cantons, with Zug, Freiburg, and Solothurn, however, remained faithful to the Church of Rome. In 1531 war broke out between the Protestants and Catholics, and at the battle of Kappel, where Zwingli was killed, the Zurichers were defeated by the Forest Cantons. The episcopal and imperial city of Geneva, which had allied itself with Bern and Freiburg against the Dukes of Savoy, became a republic in 1535, and accepted a new civil and ecclesiastical legislation under Calvin. In the following year the Pays du Vaud, long subject to the Dukes of Savoy, was conquered by Bern; the inhabitants became Protestant, and the Reformed doctrines spread into western Switzerland. During the Thirty Years' War Zurich and Bern successfully helped to maintain the neutrality of Switzerland, and by the treaty of Westphalia in 1648 the country was acknowledged by the great powers as an independent state. Bern, since the conquest of Vaud, had become the most powerful canton; the wealthy inhabitants of that city constituted themselves into a close corporation or guild, to which no new members were admitted, and, as in Lucerne, Freiburg, and Solothurn, all official posts were in the hands of the patrician families.

Zurich, Basel, and Schaffhausen were 'semi-aristocratic' cantons, the burghers having a share in the elections, from which, however, the country-people were excluded. The remaining six cantons ruled themselves in the *Landsgemeinden* or popular assemblies. The internal state of the cantons, however, owing in many cases to a tyrannical administration, showed a need of reform. The subject-territories had particularly to complain of the arbitrary conduct of the bailiffs by whom they were ruled, as well as of the inequality which existed between the inhabitants of town and country. It only required the impetus imparted by the French Revolution to produce a wide-spread rising in Switzerland. In 1798 Vaud declared its independence against Bern, and a French army came to her aid. In other parts of Switzerland similar outbreaks occurred; the French routed the troops of the Forest Cantons and those of the Bernese under General von Erlach at Fraubrunnen and Grauholz, the city of Bern was taken, and the ancient Swiss Confederation came to an end.

Till 1798 there had simply been alliances between the different cantons; no real constitution existed, and the establishment of the Helvetic Republic (the fourth phase of the Confederation) was the first attempt at a federal constitution. It was extremely unpopular; not only was it imposed by foreign pressure, but it was against the traditions of the Swiss people. The whole country was torn by two hostile factions till 1803, when Napoleon summoned representatives from both parties to Paris, and gave Switzerland a new constitution, termed the Act of Mediation. St Gall, the Grisons, Aargau, Thurgau, Ticino, and Vaud were added, making nineteen cantons in all, this being the fifth phase of the Confederation. The downfall of Napoleon brought with it the destruction of his work in Switzerland, whose perpetual neutrality as well as the inviolability of her territory was recognised by the congress of Vienna in 1815. Valais, Neuchâtel, and Geneva, which had been annexed to France under the Directory, were added to the existing cantons, which thus became twenty-two in number; each of them was represented at a diet which met alternately at Bern, Zurich, and Lucerne. The decline of the Bourbons had, too, its echo in Switzerland; the patrician families lost the ascendency they had regained at the beginning of the century, and many of the cantonal constitutions were revised, with the result that the power of the people was greatly increased.

Basel, in spite of armed demonstrations, refused to grant proportional representation, with the result that the canton was divided into two half-cantons.

Religious troubles were added to these political disputes. In Aargau, where the grand council was composed of Protestants and Catholics in equal numbers, the constitution was altered upon a basis of popular representation by which the Protestants gained numerical advantages. In 1841 two thousand Catholic peasants took up arms, but were beaten by the Protestants at Villmergen; eight convents were suppressed, and much valuable property confiscated. The democrats gained ascendency in Geneva, and in 1842 the same party obtained the upper hand in Valais. In 1844 the grand council of Lucerne entrusted the Jesuits with the direction of public instruction, with the result that the town was attacked by bands of volunteers, who demanded the expulsion of the priests. In defiance of the Federal Pact, Lucerne called to her aid the Forest Cantons, Zug, Freiburg, and Valais, together forming what is known as the *Sonderbund*, whose members declared that they would preserve this 'separate league' till the convents were re-established and the question of the Jesuits abandoned. In 1847 after the deputies of the *Sonderbund* had left the Diet it was resolved to dissolve by force of arms this league of the Catholic cantons. The federal army under General Dufour consisted of 50,000 men, the Catholics brought about half that number into the field, and after a campaign of twenty-five days Freiburg was taken, Lucerne and the smaller cantons capitulated, and the struggle came to an end. No sooner had the *Sonderbund* been dissolved than it became necessary to revive the Federal Pact, and a constitution was adopted for the whole of Switzerland, this being the seventh phase. Owing not only to the development of commerce and industry, but to the difference between the legislature in the cantons, it became necessary in 1874 to revise this constitution, and since then it has been added to and altered.

See, besides works cited at ALPS, ALPINE CLUB, TELL, &c., and others in German or French on the country by Berlepsch, Hottinger, Kaden, Egli, Emminghaus, Wirth, Dierauer, &c., and on the history by Von Müller, Morin, Knonau, Daguet, Vuillemin, Dändliker, Strickler, &c.; Gremli, *The Flora of Switzerland* (Eng. trans. 1889); Victor Tissot, *Unknown Switzerland* (Eng. trans. 1889); Sir F. O. Adams and the present writer, *Swiss Confederation* (1889); W. A. B. Coolidge, *Swiss Travel and Swiss Guidebooks* (1889); B. Literature.—The literature of Switzerland, save the unimportant part that falls under Romansch (q.v.) or Italian, is included either in German or in French literature: Bodmer and Gessner are as certainly names of mark in German literature as Rousseau or Cherbuliez are in that of France. Here it may therefore suffice to give the names of Swiss writers treated in separate articles, and refer to them: thus to the German division belong Zwingli, Bullinger, Tschudi, Bodmer, Gessner, Zimmermann, Haller, Lavater, Pestalozzi, Johannes von Müller, Fuseli, and Bitzius ('Gotthelf'); to the French Bonivard, Rousseau, Vattel, Bonnet, Benjamin Constant de Rebecque, Bonstetten, Saussure, Sismondi, Necker (and by origin his daughter Mme. de Staël), Dumont, Töpffer, Vinet, and Cherbuliez. Calvin and Beza were Genevese by residence; as were Voltaire and Gibbon for many years. The Swiss-German of the country-people is a High German patois.

Swoon. See FAINTING.

Sword, a weapon of offence consisting of a blade fitted into a hilt or handle, with a guard, the blade being formed to cut or to pierce, generally to do both. The sword is the most highly honoured of all weapons, a symbol of military dignity and authority; and it is the instrument with which the monarch confers knightly honours. Its forms and modifications, and the names under which, in different shapes, it has been known in different lands, and in successive ages, are beyond computation. It is sufficient to say that the general term includes weapons so diverse as the short cutting and piercing daggers and poignards and the ponderous two-handed swords of the 15th century. The blade may thus vary in length from a few inches to four feet and upwards. It may be furnished with a cutting edge on one side only, or on both sides. It may be uniform in breadth throughout with a truncated end, or it may taper from the hilt to a fine point. The blade, moreover, may have a piercing point alone, as in the rapier, and it may be curved throughout its entire length, as in the oriental scimitar. The hilt, with its many forms of guard, grip, and pommel, similarly adds to the variations of the weapon.

The sword, of course, could not be a weapon of primitive man; but it is easy to trace its development from the forms of weapon in use in the stone and early bronze ages. The sword came into use only when men had attained considerable skill in casting and working bronze, and the ancient bronze swords, many of which have been found throughout Europe with two-edged blades measuring two feet in length, are well finished weapons (see Vol. II. p. 477). The early Greek sword (fig. 1, *a*) was merely a strong two-edged knife; but about 400 B.C. its form was improved and its size doubled by Iphicrates. The *gladius* of the Romans (fig. 1, *b*) was still of the same form—a straight two-edged blade, heavier and longer, however, than the Greek weapon. During the early middle ages there does not appear to have been much development in the form of the sword in Europe. As shown by the Bayeux Tapestry (q.v.) and other contemporary illustrations, it continued to be a short cutting weapon, with a blade of uniform breadth bluntly pointed, and to give it balance it was channeled from the hilt for about two-thirds of its length. The cross-guard, subsequently called the quillons, was short, projecting at right angles from the blade, but sometimes bent forward in the direction of the point. With the development of armour in warfare it became necessary to give much greater heaviness and strength to the sword; the blade was greatly lengthened and tapered from hilt to point, the guard and the hilt were also

Fig. 1.

lengthened, and in this way the two-handed sword —the distinguishing arm of the 15th century—was evolved. In Scotland several of these ponderous weapons are preserved, and traditionally associated with the names of Wallace, Bruce, and other contemporary heroes; but such swords were really not in use at so early a period, and so late as 1567 Lindsay proposed to meet Bothwell in single combat at Carberry, armed with 'the famous two-handed sword of Archibald Bell-the-Cat.' With the introduction of the two-handed sword, the use of a shield being no longer possible, the guard gradually became more complicated, so as to give greater protection to the hands of the swordsman, and from the use of shell-guards and ring-guards, &c. the basket-hilt, as applied to lighter swords, by degrees developed. The ordinary basket-hilt sword, such as is worn by officers of Highland regiments at the present day, is of Italian origin, and grew out of the Venetian *schiavone*. The rapier—a piercing weapon only, with a blade tapering to a fine point—came into use in the early part of the 16th century, and in the 17th century it became the weapon of fencing and duelling. From very early times Toledo, Seville, and some other Spanish towns had a high reputation for the excellence of the swords made by their armourers, and when to their own skill was added the perfect craftsmanship of their Moorish conquerors the renown of Spanish blades became supreme. In the North Italian towns also, as well as at Solingen and Passau in Germany, swords of famous quality were fabricated. In Scotland during the 17th and 18th centuries Ferrara blades were held in the highest esteem, and were a very common possession. Who the original maker of these famous blades was is not known, but in the 16th century there was a family of armourers named Ferrara (q.v.) in North Italy, one member of which, called Andrea, was born in 1555. It is, however, obvious from the long period over which the manufacture extended that 'Ferrara' became more a trade-mark than a maker's name. Many magnificently finished examples of swords from the Renaissance period downwards are preserved as art treasures in public and private collections. On the enrichment of these the highest efforts of artificers and artists have been expended, and they have been lavishly adorned with gold enamels and precious stones. Additional interest is given to some of these swords by the legends attaching to them, and by the historical importance of the personages to whom they belonged. Mythical stories are also numerous of craftsmen endowed with marvellous powers, and with whose blades unheard-of feats could be performed. In modern warfare the sword possesses little more than an honorary military significance.

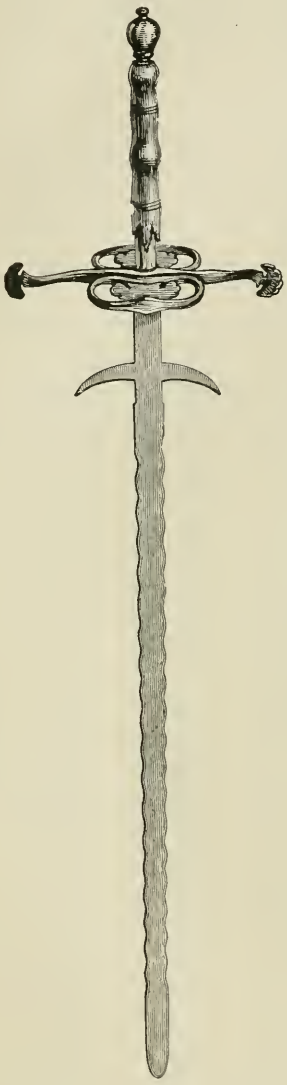

Fig. 2.—Two-handed Sword, preserved in Duff House.

See DAMASCENING, and, besides works cited at FENCING and DUELLING, James Drummond's *Ancient Scottish Weapons* (1881), Sir R. Burton's *Book of the Sword* (vol. i. 1884), Sir F. Pollock's *Oxford Lectures and other Discourses* (1891), Captain A. Hutton's *The Swordsman* (1891), and Vigeant's *Ma Collection d'Escrime* (1892).

Sword-fish (*Xiphiidæ*), a family of spiny-rayed Teleostean fishes, abundantly represented in tropical and subtropical seas. They are among the largest bony fishes, sometimes measuring 12 to 15 feet in length. The sword, which may be over 3 feet long, is formed from a compressed prolongation of the upper jaw, and is often strong enough to stab whales fatally, or less advantageously to pierce the bottom of a ship or the planks of a boat. The genus Xiphias is well represented by the common sword-fish (*Xiphias gladius*), abundant in the Mediterranean and in the warmer parts of the Atlantic and Pacific, and of rare occurrence on British coasts. They are found in schools, but never in close company; they feed on such fishes as mackerel, menhaden,

Common Sword-fish (*Xiphias gladius*).

and herring, which they kill with the sword, and also it seems on cuttle-fish. The flesh is somewhat oily, but is highly esteemed, both fresh and salted. With the regular sword-fish fishermen, harpooning is the mode of capture. The genus Histiophorus, the members of which are also called sail-fishes or bill-fishes, has a greatly developed dorsal fin or sail, and has long, compressed ventral fins which are absent in Xiphias. As in the true sword-fish, the young, with undeveloped swords, are very different from the adults. In summer Histiophorus occurs in the American seas as far north as New England, but it is strictly a tropical fish. Another form—the spear-fish—of similar distribution, is generally referred to a distinct genus, Tetrapturus. The bony sword-fishes must not be confused with the cartilaginous Sawfishes (q.v.) belonging to the Elasmobranch genera Pristis and Pristiophorus.

Sybaris, an ancient city of Magna Græcia, stood on the Gulf of Tarentum, and was founded about 720 B.C. by colonists from Achæa and Trœzene. The fertility of its soil and its liberal policy favoured commerce, and the city flourished and became very prosperous. Its citizens led such luxurious and self-indulgent lives that their name became a by-word amongst the peoples of antiquity. Quarrels between the democratic and oligarchic factions led in 510 B.C. to a war with the neighbouring colony of Crotona (q.v.), in which the forces of the Sybarites were totally routed, their city captured, and the site where it stood obliterated by the victors, who turned upon its ruins the waters of the adjacent river Crathis. See THURII.

Sybel, HEINRICH VON, German historian, was born at Düsseldorf on 2d December 1817. Perhaps the most eminent of Ranke's pupils, he became successively professor of History at Bonn (1841), Marburg (1846), Munich (1856), and Bonn again (1861), in Munich also filling the post of secretary to the Historical Commission of the Royal Academy of Sciences. At various times between 1848 and 1880 he sat in the parliaments of Hesse, the North German Confederation, and Prussia, as a National Liberal and an opponent of the Ultramontanes. In 1875 the Prussian government made him director of the state archives at Berlin; and as such he was instrumental in publishing the Political Correspondence of Frederick the Great, and in organising at Rome a 'Prussian station for Researches in German History,' besides assisting in the publication of the *Monumenta Germaniæ Historica.* Moreover he founded and edited the *Historische Zeitschrift.* Sybel's first book was a history of the First Crusade (1841), in which, applying the critical methods of his master, he destroyed the accepted opinions of centuries; his next the *Entstehung des deutschen Königthums* (1844). Then, after an interval of nine years, came his first masterpiece, *Geschichte der Revolutionszeit von 1789 bis 1795* (3 vols. 1853–58; 4th and greatly improved ed. 1877), a cool, sober, and dignified statement of the historic causes and consequences of that eventful period, based upon a critical examination of official documentary evidence. A second part or continuation, bringing the narrative down to 1800, was published in 2 vols. in 1872–74. His second great work is entitled *Die Begründung des deutschen Reichs durch Wilhelm I.* (5 vols. 1889–90; English trans., New York, 1891), exhibiting the same qualities. Von Sybel, who also published three volumes of *Kleine Historische Schriften* (1863–81), died at Marburg, 1st August 1895.

Sycamine, a tree mentioned in Scripture, and supposed to be the Black Mulberry (q.v.).

Sycamore (*Sycomŏrus*), a genus of trees of the natural order Moraceæ, regarded by many botanists as a mere sub-genus of Ficus (see FIG), and differing from the true figs only in the elongated, straight, thickened, and club-shaped stigma. The species are chiefly African, but the geographical range extends also into the west of Asia. Some of them attain a large size and a great age. The Egyptian Sycamore (*Ficus Sycomorus*), supposed to be the sycamore of the Bible, is a large tree, abundant in Egypt and in Syria and

Branch of *Ficus Sycomŏrus*; *a*, fruit.

other parts of the west of Asia, often planted near villages for the sake of its shade, its wide-spreading head sometimes covering a space 40 yards in diameter. The figs are top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well flavoured, and somewhat aromatic. The wood is light, porous, and of little value. Other species are found in Abyssinia, South Africa, &c.

The sycamore-tree of England is a species of Maple (q.v.), and in Scotland is usually called plane-tree (though neither plane nor sycamore). In some parts of North America the name of sycamore is given to the Plane (q.v.) of that country, *Platanus occidentalis.*

Sycosis, a pustular eruption on the scalp or bearded part of the face, due to Ringworm (q.v.), Acne (q.v.), or Impetigo (q.v.).

Sydenham, a district in Lewisham parish, Kent, 8 miles S. of London. It has become of world-wide celebrity in connection with the Crystal Palace, which, however, is really in the adjoining parish of Lambeth, Surrey, and which was erected in 1852–54, chiefly from the materials of the building of the Great Exhibition (1851), and under the superintendence of Sir Joseph Paxton. The cost of the erection and appointment of the Crystal Palace amounted to nearly £1,500,000. The building is 1608 feet long, 390 wide across the transept, and 175 feet high, the height of the two water-towers being 282 feet. The chief arts and sciences illustrated by the collections within the Palace and grounds are Sculpture, Architecture, Painting and Photography, Mechanics and Manufactures, Botany, Ethnology, Palæontology, Geology, and Hydraulics. There are two concert-rooms, within the larger of which on occasion of the triennial Handel festivals (since 1859) performances have taken place with 4000 vocalists and instrumentalists. Classical Saturday concerts are held during the winter season. The park and gardens occupy nearly 200 acres, and are adorned with sculptures, stone balustrades, &c., and fountains which are perhaps the finest in the world. Cricket and football matches and cycle and other sports are held in the grounds. On 30th December 1866 there was a fire in the north wing, doing damage to the amount of £150,000. The palace, whose finances have more than once been seriously embarrassed, is directly accessible from all the London suburban railways.

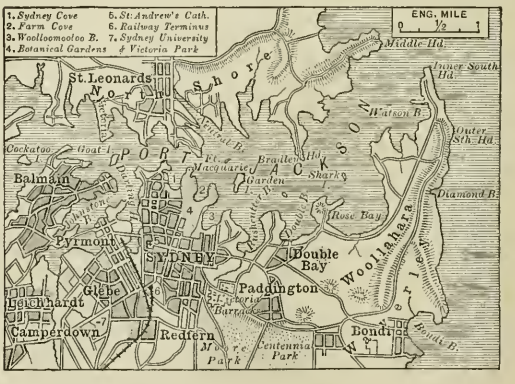
Sydenham, Floyer (1710–87), an amiable and accomplished man of letters, whose privations and miserable end brought about the foundation of the Literary Fund, graduated at Wadham College, Oxford (M.A., 1734), and in his fiftieth year began the publication, by subscription, of a complete English version of Plato's *Dialogues*, each to be prefaced by a critical introduction and illustrated with explanatory notes. The *Io* appeared first, and was followed by the *Hippias Major* and *Minor* and the *Banquet*. Superior in style and scholarship to the general run of 18th-century translations, its merits found scant appreciation from a world not yet ripe for Plato's philosophy; subscribers were few, and the public were not tempted by the low price of the book to purchase or interest themselves in it. Undaunted by this failure, Sydenham made another attempt at arousing a taste for Greek philosophy by his dissertation on Heraclitus (1775). This too, had no market, any more than his publication entitled *Onomasticon Theologicum* (1784). Three years afterwards he was arrested at the suit of a victualler for unpaid meals, and died in prison.

Sydenham, Thomas, the 'sommo Ippocratista inglese' (supreme English Hippocratist), as Puccinotti styles him, was born in 1624 at Winford Eagle in Dorsetshire, and died in London, 29th December 1689. That he belonged to one of the county families; that at eighteen he was entered at Magdalen Hall, Oxford; that his studies were, after two years, interrupted by his having to serve as an officer in the parliamentarian army; that his Oxford curriculum ended in 1648 when he graduated M.B., and shortly after became a Fellow of All Souls—is the sum of our knowledge as to his youth and early manhood. For the next fifteen years we lose sight of him, though he probably spent some of them at Oxford, if not also at Montpellier. We find him in London in 1663 as a licentiate of the College of Physicians, publishing his *Methodus Curandi Febres* in 1666; and ten years thereafter taking his M.D. at Pembroke Hall, Cambridge. With the College of Physicians, or even with Oxford, he seems to have had no subsequent connection; and all through his life he was not a *persona grata* with the faculty. The 'Iatro-physical' and 'Chemiatric' theories in fashion at the time he treated with scant consideration, and looked upon chemistry itself as a mere branch of the apothecary's business. But from his intimacy with John Locke and Robert Boyle we might infer his appreciation of the true philosopher and the true physicist, even if we did not know his profound mastery of the Hippocratic method and his perfect assimilation of the Hippocratic spirit. In 1668 he published a second edition of his book on fevers, adding to it a chapter on plague, with a fine poem in Latin elegiacs addressed to him by Locke. A third and enlarged edition, entitled *Observationes Medicæ*, appeared in 1676. In 1680 he published two *Epistolæ Responsoriæ*, the one 'On Epidemics,' and the other on the 'Lues Venerea.' His *Dissertatio Epistolaris* on confluent smallpox and hysteria (1682) was followed next year by his yet more famous *Tractatus de Podagra et Hydrope*. In 1686 appeared his *Schedula Monitoria de Novæ Febris Ingressu*, and in 1692 his last work, *Processus Integri*, an outline of pathology and therapeutics. An acute attack of gout carried him off in his sixty-sixth year, and he was interred in St James's Church, Piccadilly, where in 1810 the College of Physicians erected a mural tablet to his memory.

Sydenham's place in the history of medicine has already been given. Seemingly behind his age in science, he was really ahead of it in practice. The new-born anatomy and physiology had with premature confidence lent itself to theories, mathematical and chemical, which were utterly at variance with the phenomena of disease as noted at the bedside. He soon satisfied himself that it was hopeless to reconcile them, and that meanwhile, with practical English sense, it was his business to get his patients well. In acute disease he read the forth-putting of that activity by which nature sought to right herself—an activity to be watched and, when possible, to be assisted. Called in to a patient who had been deplorably reduced by lowering treatment, he reversed the practice and 'ordered a roast chicken and a pint of canary.' Chronic diseases he also viewed with the eye of Hippocrates, as due to habits or errors for which we ourselves are mainly responsible, and these he met by appropriate changes in diet and mode of life. The Hippocratic 'natural history method' of looking at and treating ailments of all kinds it was his great merit to have intelligently revived. Among special contributions to nosology he may be said to have first diagnosed scarlatina and classified chorea, while Puccinotti claims for him the title of 'restorer of the curative treatment of smallpox.' Gout was another ailment on which he left a memorable mark. It was as a practitioner, however, that his powers worked most freely and most felicitously.

See Puccinotti's *Storia della Medicina*, vol. iii.; Häser's *Geschichte der Medicin;* Dr W. A. Greenhill's admirably edited *Opera Omnia* of Sydenham, with Dr R. G. Latham's English rendering of the same (both published by the Sydenham Society, which was founded in 1843); Dr John Brown's *Locke and Sydenham;* and Picard, *Sydenham, sa Vie, ses Œuvres* (Paris, 1889).

Sydney, the capital of New South Wales, and the oldest city in Australia, is situated on the southern shores of Port Jackson, and was named after Thomas Townshend, first Viscount Sydney (1733–1800), who was then Secretary of State for the Colonies. The first party of British settlers that reached New Holland were landed at Botany Bay (q.v.) on January 20, 1788. The spot which they here selected being found ineligible, it was abandoned a few days afterwards, and the infant settlement was transferred to a point about 7 miles farther to the north, the place where Sydney



now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water being found there, flowing into the deep inlet known as Sydney Cove, one of the numberless bays into which the basin of Port Jackson is divided. This last-mentioned magnificent expanse of water, completely landlocked, and admitting vessels of the largest size, extends for some 20 miles inland, ramifying in every direction. Its bold and rocky shores, covered with luxuriant vegetation, present a succession of picturesque and beautiful landscapes. The hills which

form the general outline of the harbour often rise to a height of from 200 to 250 feet. In other points the coast presents a lower level, consisting of a series of terraces and smooth sandy beaches. Perhaps there are few positions on the habitable globe more obviously suitable for the foundation of a great metropolis than are the shores of Sydney Harbour. The narrow entrance of Port Jackson—through the 'Heads,' which are indicated by the Macquarie lighthouse, its electric light visible 30 miles at sea—might easily be made inaccessible to any hostile fleet; whilst the central position of Sydney makes it necessarily an emporium for many of the British dependencies in the southern hemisphere. The immense coal formation of East Australia extends north and south for some 500 miles, with a breadth of from 80 to 100 miles. Sydney stands nearly in the centre of this great carboniferous basin; and at various points within a radius of from 30 to 100 miles large quantities of coal are raised for colonial consumption as well as for export. The sandstone rock upon which the city is erected affords a valuable material for building.

Since the abolition of transportation the growth of Sydney has been rapid, the pop. in 1862 amounting to 93,596, in 1881 to 220,427, and in 1891 to 386,400. For many years Sydney enjoyed a monopoly of the commerce of these antipodean regions, but its trade has now become largely shared by Melbourne, Adelaide, Brisbane, and other colonial ports. It must, however, continue the principal outlet for the productions and commerce of extensive pastoral and mineral districts on the north-west, west, and south-west. The city, which has rapidly increased of late years, extends several miles inland from the waters of Port Jackson, the whole of the water frontages from Fort Macquarie, 8 miles from the 'Heads,' to the head of Darling Harbour, a distance of several miles, being occupied for wharfage purposes, those at Circular Quay being used by the vessels of the P. and O., Orient, and other large ocean steamship companies. In 1895, 1307 vessels, with an aggregate tonnage of 1,669,654 tons, cleared the port of Sydney.

The streets in the older parts of the town are narrow and irregular: in the newer portions care has been taken to avoid these defects; and several of the modern streets, from their breadth and the size and style of the buildings, are not behind those of the principal towns of Europe. The shops, warehouses, and private buildings in the leading streets present long and compact lines of well-built stone edifices, often assuming a very ornate and ambitious style of architecture. The chief thoroughfares are paved, and lighted with gas, several with the electric light, and a system of underground drainage has been carried out at a cost of nearly half a million sterling. There is also an abundant supply of pure water, considerably in excess of present requirements, obtained from the Nepean River, near Penrith, several miles from Sydney. There are numerous parks near the city. The Botanical Gardens, the finest in the colonies, cover 38 acres. Sydney has one shipbuilding establishment. The Fitzroy Dry Dock, originally intended for vessels of the Royal Navy, can take in vessels of the largest size, and has been supplemented by one of the most extensive graving-docks in existence. Steps have been taken to put the city in a state of defence, and forts and batteries armed with powerful Armstrong guns have been erected. Sydney is a first-class naval station and the headquarters of the Australasian fleet.

Amongst public buildings by far the most important edifice, not only in Sydney but in the whole of the Australian colonies, is the university (1852), which stands on a commanding height, and in the centre of a domain of about 150 acres. The principal façade is 500 feet in length, and is flanked at its western end by the Great Hall, the proportions of which are such that, were it in England, it would rank as the third in point of size. There are three affiliated colleges—Church of England, Roman Catholic, and Presbyterian, besides the Women's College. The university, erected out of public funds, has a subsidy of about £12,000 a year from the state; and each of the affiliated colleges receives aid towards the stipends of the warden and rector. Recently the university funds have become considerably augmented by munificent bequests, which have enabled the work of university education to become considerably extended. It is open to both sexes, and is empowered to confer degrees in arts, law, and medicine; but, so far as the university is concerned, instruction is limited to purely secular teaching. The metropolitan cathedral of St Andrew is a handsome building in the later Perpendicular style of architecture. The Roman Catholic cathedral of St Mary, burnt in 1865, and since rebuilt, is one of the finest ecclesiastical structures in Australia. Many of the city and suburban churches, upwards of 120 in number, are tastefully designed. There are numerous elementary, advanced, and technical schools, and a technical university and technological museum. Amongst the buildings devoted to secular purposes the most imposing and effective, in point of size and architectural design, are the museum, Colonial Secretary's office, lands office, post-office, customs office, town-hall (possessing the largest organ in the world), and public grammar-school. The neighbourhood of Sydney, especially the shores of the numerous bays and the Parramatta and Lane Cove rivers, is studded with elegant villas and snug cottages, surrounded by their park-like grounds, and gardens of orange-trees, bananas, and numberless semi-tropical plants. There are numerous industrial establishments, several on a most extensive scale, but Sydney is essentially a commercial rather than a manufacturing city. Sydney has several theatres, a free library, art-gallery, museum, hospitals, mechanics' institutes, and asylums. Here in January 1901 were held the ceremonies accompanying the inauguration of the Australian Commonwealth. (See AUSTRALIA, NEW SOUTH WALES.)

Sydney, a small town of Cape Breton (q.v.), with a large coalfield.

Sydney, ALGERNON. See SIDNEY.

Syene. See ASSOUAN.

Syenite, a rock composed essentially of orthoclase and hornblende. It is granitoid and wholly crystalline—i.e. it contains no non-differentiated mineral matter. Quartz is sometimes sparingly present, and other accessory minerals may occur, such as oligoclase, sphene, zircon, apatite, ilmenite, &c. *Elæolite-syenite* is characterised by the presence of elæolite—an altered variety of nepheline. Syenite is an igneous rock of deep-seated origin, occurring in the form of bosses and veins. It is not known in the British Islands, but is met with in various countries in Europe and in America.

Sylhet, or SILHET (*Srihatta*), a British district in the extreme south of Assam (q.v.), partly a rich alluvial tract, but to the extent of 32 per cent. uncultivable waste, has an area of 5413 sq. m. and a pop. of 2,000,000. The chief town, Sylhet, on the Surmá River, has a pop. of 15,000, and some trade and manufactures.

Sylla. See SULLA.

Syllabub, a culinary preparation, formerly much used, consisted of sugar and cream, flavoured

with brandy, sherry, and lemon rind and juice, worked into a froth, and served in glasses. White of egg and verjuice seem also at times to have been ingredients.

Syllabus, a term from the Greek usually applied to a compendium or abstract of a lecture or series of lectures, is specially used of the papal syllabus which accompanied the Encyclical (q.v.) *Quanta Cura*, addressed by Pius IX. to all Catholic bishops on 8th December 1864. This syllabus is a catalogue of eighty errors or heresies, and implicitly enjoins the opposite truths; and by Protestants has generally been regarded as a declaration of war against all freedom of thought, modern civilisation, and social progress, and a reassertion of the extravagant claims of the mediæval papacy to supreme authority on every subject. The syllabus is divided into ten sections, condemning (1) pantheism, naturalism, thorough-going rationalism; (2) milder rationalism; (3) latitudinarianism; (4) socialism, communism, secret societies, &c.; (5) errors as to the rights of the church; (6) as to the constitution of society; (7) as to ethics; (8) as to marriage; (9) as to the temporal power of the pope; (10) the errors of modern liberalism. The infallibility of the pope is indirectly asserted, as is the right of the Roman Catholic Church to exercise complete control over education, literature, and science. Catholics have debated amongst themselves whether the syllabus is an *ex cathedrâ* papal utterance, and so to be regarded as *de fide* and infallible, in terms of the Vatican decree.

See Mr Gladstone's *Vatican Decrees in their bearing on Civil Allegiance* (1875); Cardinal Manning's reply with the same date and title, and the *Letter to the Duke of Norfolk;* and, again, Mr Gladstone's answer in *Vaticanism* (1875). The text of the syllabus will be found in Schaff's *Creeds of Christendom*, vol. ii.

Syllogism. See Logic.

Sylphs, in the fantastic system of the Paracelsists, are the elemental spirits of the air, just as the salamanders are of fire and the gnomes of earth. They hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul, and when they die nothing is left. In form they are ruder, taller, and stronger than men, but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children and of simple harmless people; they even marry with our race, like the Undines and the Gnomes, and the children of such a union have souls and belong to the human race. In common usage the term sylph is applied to a graceful maiden—a change of meaning probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope the sylph that guards Belinda is masculine, yet the poet so refined and etherialised his spiritual agents that they soon came to be identical with ideas of feminine grace and beauty.

Sylt, a narrow island, 23 miles long, off the west coast of Sleswick, with a population of 3000, many Frisians. The chief town is Keitum.

Sylvester, name of three popes.—Sylvester I. (314–335) is claimed to have baptised Constantine the Great, and to have received from him the famous Donation. He was canonised, his day falling on December 31.—Sylvester II., whose name was Gerbert, was born at Aurillac in Auvergne about 950, and early acquired from his extraordinary attainments in philosophy, but especially in mathematics and chemistry, the reputation of being in league with the Devil. Made abbot of Bobbio by Otto II., he opposed the papal claims at the Synod of Rheims (991), but afterwards became reconciled with the pope, and was made Archbishop of Ravenna (998), from which he climbed into the papal chair in 999, which he filled till his death in 1003. His *Letters* were edited by Olleris (Clermont, 1867). See the works thereon by J. Havet (1889) and Boubnov (1889), and the studies by Werner (1878), Nagl (1888), and Weissenborn (1888).—Sylvester III. (1044–46), Antipope to Benedict IX., set aside at the Synod at Sutri.

Sylvester, James Joseph, mathematician, was born in London, 3d September 1814, studied at St John's College, Cambridge, and was successively professor in University College, London, in the University of Virginia, at Woolwich, in the John Hopkins University, and at Oxford (Savilian professor, 1883–94); and he published many memoirs, received many medals and honours, was LL.D., D.C.L., F.R.S., and fellow of many foreign academies. He died 15th March 1897. See the notice by Cayley in *Nature*, vol. xxxix.

Sylvester, Joshua, was born in 1563. His life was divided betwixt merchandise and poetry, but in neither did he achieve success. Of his original works the human memory retains no trace, save perhaps only in the title of the poem published about 1620, entitled *Tobacco Battered and the Pipes Shattered by a Volley of Holy Shot thundered from Mount Helicon;* but in virtue of the great though short-lived popularity obtained by his English version of the *Divine Weeks and Works* of Du Bartas he lives in literary history a kind of shadowy life. He led a somewhat wandering existence, and died at Middelburg in Holland in 1618. His Works (1641) were reprinted by Grosart in the 'Chertsey Worthies Library' (1878).

Sylviadæ. See Warbler.

Sylviculture. See Arboriculture.

Symbiosis (Gr., 'living together'), a biological term introduced by De Bary to denote certain kinds of physiological partnership between organisms of different kinds. Consortism is synonymous. As there are many kinds of organic association, it is convenient to restrict the term symbiosis to such intimate and complementary partnerships as exist between algoid and fungoid elements in lichens, or between unicellular Algæ and Radiolarians. In organic nature there is no isolation; no organism lives or dies to itself; there are countless vital associations, some very indirect and external—e.g. the mutual dependence of some flowers and insects—others very direct and intimate, as in the symbiosis of Algæ and Radiolarians. It often happens that two organisms live together without there being any apparent vital bonds between them; thus, Diatoms may be 'epiphytic' on Algæ; Algæ, lichens, mosses, ferns, orchids, &c. are often epiphytic on trees; many Algæ are 'epizoic' on animals—e.g. those which live among the hairs of sloths; and one animal may be epizoic on another, as sponges often are on zoophytes. Again, there may be external partnerships, such as those between pilot-fish and shark, or between beef-eater birds and wild cattle. These suggest cases of mutualism or Commensalism (q.v.), such as the partnership between certain hermit-crabs and sea-anemones. Probably the constant occurrence of colonies of the Alga Anabæna in the leaves of the aquatic plant Azolla is a similar

partnership. Alike in symbiosis and in commensalism the partnerships are advantageous to both of the associated organisms, and are therefore to be distinguished from Parasitism (q.v.), in which the benefit is all on one side. It is useful to distinguish these different grades of association, but it cannot be pretended that the distinctions are rigid.

Apart from lichens, the partnership of unicellular Algæ with Radiolarians is the best-known case of symbiosis. The partner Algæ—known for a long time as 'yellow cells'—used to be variously interpreted as reproductive cells, secretory cells, reserve stores, parasites, and so on; but the researches of Geddes, Brandt, and others demonstrated their algoid and truly symbiotic nature. They have a cellulose wall (except in the Acanthometridæ among Radiolarians), a nucleus, two pigments, of which one is at least closely analogous to the ordinary chlorophyll of plants; they are able to live and multiply after removal from their host or after its death; in sunlight they evolve oxygen and form starch; they multiply as do free unicellular Algæ. From his experiments Geddes inferred that the starch formed by the Algæ may be absorbed by the Radiolarians; that when they die the Algæ are digested by their partners; that during life they absorb carbonic acid and nitrogenous waste from the Radiolarians and in turn liberate oxygen which may accelerate the vital functions of their bearers. It seems that the partnership is distinctly advantageous, for the Algæ flourish and multiply, and those Radiolarians which are without Algæ are few and much less common than the vast majority which exhibit symbiosis. Brandt's results are for the most part in agreement with those of Geddes, though divergent on some points of details. The Algæ may belong to a distinct genus (Zooxanthella of Brandt, Philozoon of Geddes), or may be simply the swarmspores of various olive-green seaweeds.

Similar symbiotic Algæ occur in some Foraminifers, in several Cœlenterates, especially otherwise colourless sea-anemones, and, according to Geddes, in some species of the Turbellarian Convoluta. Brandt maintains that in the fresh-water sponge (Spongilla) and in the fresh-water Hydra there are symbiotic Algæ of the genus Zoochlorella, but Ray Lankester has shown to the satisfaction of most naturalists that the pigmented bodies in those animals are no more symbiotic Algæ than are the green corpuscles in the leaf of a buttercup. Many marine sponges are infested by various kinds of Algæ, but we do not know that they exhibit any real symbiosis.

In regard to some green Protozoa there is much dispute whether the green colour is due to chlorophyll bodies or to symbiotic Algæ. Some forms—e.g. *Stentor polymorphus*, *Coleps viridis*, *Ophrydium viride*, and *Vorticella chlorostigma*—also occur in a colourless state. Some observers regard the bodies as Algæ, others as chlorophyll corpuscles. 'Zoochlorellæ,' found in species of Paramœcium, Stentor, and Stylonichia, have been pronounced by good authorities symbiotic forms of the Protococcus-like Chlorella, which have also been discovered living freely. Thus it appears that, while many cases of symbiosis are indubitable, there are other cases in regard to which judgment must be for a time suspended.

See Commensalism, Epiphytes, Lichens, Parasitic Animals; O. Hertwig, *Die Symbiose* (Jena, 1883); Geddes, *Nature*, xxv. (1882); Brandt, *Archiv. f. Anat. u. Physiol.* (1882), and *Mittheilungen Zool. Stat. Neapel*, iv. (1883); Ray Lankester, *Nature*, xxvii. (1882).

Symbol (Gr. *symbolon*, 'a sign') is sometimes used of arbitrary or other conventional marks (as of letters of the alphabet, numbers, &c.) which greatly abbreviate methods of scientific expression, as in algebra and mathematics, and especially in chemistry (for chemical symbols, see Chemistry, Atomic Theory). Alchemy and Astrology (q.v.) raised a large crop of symbols; from the latter astronomy has derived not a few. But symbol is now usually almost synonymous with emblem—a concrete and visible figure standing for something moral, intellectual, or religious. A lion is the symbol of courage, a lamb of meekness, &c. Greek and Roman mythology produced a large number of symbols—the trident of Neptune, the peacock of Juno, &c. Early Christian symbolism—originating mainly in a Greek colony in Rome—may be traced in the Catacombs, and an outline of its development has been already sketched in the article Catacombs. The greatest number of symbols are those which represent Christ—some mere letters or combinations of letters, as the Monogram (q.v.), composed of A and Ω, of IX and ☧ (for *Christos;* see Cross), of IHΣ (initials of *Iesous*). Of another kind is the word IXΘΤΣ, the Greek work for fish, the several letters standing for the initial letters of the Greek words Ἰησοῦς Χριστὸς Θεοῦ Υἱὸς Σωτήρ. The symbol of a pictured fish is also used for Christ; and some contend that this symbol, for whatever reason, was in use before the acrostic word was invented or thought of. Then there are pictures of the Good Shepherd, the True Vine, &c. (see also Saint). So innumerable devices symbolised facts of Christian history, or aspects of Christian truth. In her ritual the Roman Catholic Church has given copious expression to religious symbolism. In architecture also symbolism appears in the cruciform shape of churches, in Orientation (q.v.), &c. In theological language it should also be noted that symbol sometimes means, like the Greek *symbolon*, a creed; hence symbolics is the study of the history and contents of Christian creeds.

On symbolism in art, see Mrs Jameson's *Sacred and Legendary Art*, the last volume, by Husenbeth, of Baring-Gould's *Lives of the Saints* (1872–92), Munter's *Sinnbilder* (1825), Auber's *Symbolisme Religieux* (1850), Tyrrwhitt's *Art Teaching of the Primitive Church* (1873), Miss Twining's *Symbols and Emblems* (1885), Clement's *Christian Symbols* (Boston, 1886), Miss Stokes's translation of Didron's *Christian Iconography* (1886), Allen's *Early Christian Symbolism in Great Britain and Ireland* (1887), Hulme's *Symbolism in Christian Art* (1891).

Syme, James, surgeon, was born, the son of a Fife lawyer, in Edinburgh, 7th November 1799, and received a thorough education in arts and medicine in the university of that city. Liston appointed him anatomical demonstrator. In 1818 he announced in *Annals of Philosophy* a method of making waterproof cloth by means of caoutchouc dissolved in coal-tar naphtha—a process for which a patent was taken out by Macintosh of Glasgow. From 1823 to 1832 he lectured on surgery, and, when refused a surgical appointment in the Edinburgh Infirmary, he established Minto House Hospital at his own expense, where he delivered a clinical course from 1829 to 1833. In 1831 appeared his well-known treatise on *The Excision of Diseased Joints;* and in 1832 his *Principles of Surgery*, which went through many editions, and which established his reputation as a teacher of the first rank. In 1833 he was elected to the chair of Clinical Surgery in the university, and in 1838 he was appointed surgeon in ordinary to the Queen in Scotland. In 1848 he gave up his Edinburgh chair to fill that vacated in London by the death of Liston; but collegiate misunderstandings induced him, after five months, to return to Edinburgh, where he was reappointed to his old chair. His life abounded in controversies. As an operator Syme had no superior; as a teacher he had no equal.

His innovations in the practice of his art were characterised by so much ingenuity, controlled by such scientific caution, that they were everywhere adopted. One of the best known of his pupils, Dr John Brown, terms him (*Horæ Subsecivæ*, i.) the 'best and ablest and most beneficent of men,' and the greatest surgeon Scotland ever produced. He further calls his spoken or written style 'the perfection of terse clearness.' Syme was a contributor to the *Monthly Medical Journal*, and was also the author of treatises on *Diseases of the Rectum*, on the *Pathology and Practice of Surgery* (1848), on *Stricture of the Urethra and Fistula in Perinco* (1849), on *Incised Wounds*, &c. He died June 26, 1870. See the *Memoir* by Dr Paterson (1874).

Symington, William (1763–1831), one of the inventors of steam-navigation. See Ship-building, Vol. IX. p. 402.

Symmachus, Quintus Aurelius, a distinguished Roman orator, who flourished from 340 till 402 A.D., was educated in Gaul, and became prefect of Rome in 384 under Theodosius the Great, consul in 391. He was sincerely devoted to the old religion, but his purity and nobility of character were worthy of the highest Christian type. His extant writings consist of ten books of Letters, three panegyrics on Valentinian I. and Gratian, and fragments of six senatorial orations. The fragments of the orations were first discovered by Cardinal Mai in a palimpsest, part of which is at Milan, part at the Vatican, and were successively published in 1815 and 1825. Many corrections were made in the collation made by O. Seeck, which were followed in the edition included in the *Monumenta Germaniæ Historica* (vol. vi. Berlin, 1883). See Morin's *Étude* (Paris, 1847).

Symonds, John Addington, English man of letters, was born at Bristol on 5th October 1840, was educated at Harrow and Balliol College, Oxford, won the Newdigate prize, and was elected a Fellow of Magdalen College in 1862. His first book, *Introduction to the Study of Dante* (1872), was a sort of commentary on the great Italian's poem; it was followed by a laudable endeavour to present in readable English the results of the investigations of scholars in Greek learning—*Studies of the Greek Poets* (2 vols. 1873–76). But his most notable achievement is *The Renaissance in Italy*, a history of an eventful period written in a highly polished style, with fairly good judgment, and an extensive knowledge of the actors and events of the epoch described. It embraces four parts and a couple of supplementary volumes—*The Age of the Despots* (1875), *The Revival of Learning* (1877), *The Fine Arts* (1877), *Italian Literature* (2 vols. 1881), and *The Catholic Reaction* (2 vols. 1886). *Shakespeare's Predecessors in the English Drama*, published in 1884, contains the results of thoughtful study in English literature. Symonds has written, besides the books named, two or three volumes of travel sketches in Italy and elsewhere; the monographs *Shelley* and *Sir Philip Sidney* for the English Men of Letters series and *Ben Jonson* for the English Worthies series; a translation of the *Sonnets of Michaelangelo and Campanella* (1878), one of Benvenuto Cellini's autobiography, and an interesting collection of students' Latin songs of the 12th century under the title of *Wine, Women, and Song; Mediæval Songs in English Verse* (1884); *Life of Michaelangelo* (2 vols. 1892); some volumes of verse; and an account of his enforced residence at Davos (1892). He died at Rome, 18th April 1893. See his *Miscellanies* (1895); and the biography by Horace F. Brown (1894).

Sympathy. See Antipathy; for the Sympathetic Powder, see Digby; for the Sympathetic System, see Nervous System.

Symphony, in Music, a form of orchestral composition. The name was originally applied to the purely instrumental portions of works primarily vocal, under it being included overtures to operas and oratorios as well as ritornelli and the introductions to choruses and arias. It received its first restrictive meaning towards the end of the 17th century when, under Lulli and Alessandro Scarlatti, the various instrumental pieces in the operas began to grow in importance: it was then reserved for the opening section or overture, which consisted of a series of contrasted movements without definite rule as to their number or arrangement. Subsequently a plan, attributed to Lulli and known as the 'ouverture à la manière française,' prescribed three movements, the first and third slow and the middle one quick and bright. Its place was eventually taken by the 'Italian overture,' in which the three movements were retained but in inverse order, the first and last being quick and the second slow. This form was identical with that of the clavier-sonata, to which, however, the overture long remained inferior in respect of the internal structure of its movements, few composers caring to show themselves at their best in pieces to which talkative audiences paid little heed. As a further result of such inattention it seemed to be forgotten that the overture should fitly foreshadow the work which it preceded: its material, consequently, became distinct and independent, so that it was only natural that the best examples should in course of time find their way into the concert-room, where they met with a more courteous reception. A new outlet being thus provided, original works were soon forthcoming; and with the liberation of the symphony from its operatic surroundings its development as an abstract form of art may be said to have begun. Meanwhile the reinforcement of the ordinary stringed orchestra by certain wind-instruments introduced fresh possibilities of expression which reacted on the material of which the movements were composed. In some of Stamitz' symphonies a fourth movement is also found in the shape of a minuet and trio; and with this the external outline reaches completion. It was not, however, until 1788, the year in which Mozart wrote his greatest examples, that the symphony attained the rank of an important work of art. In these three works, the E flat, G minor, and C major symphonies, an extraordinary advance is visible both in expression and in richness of instrumental effect. Haydn, though born nearly twenty years before Mozart, wrote his most important symphonies during the eighteen years he survived his younger contemporary. But the symphony was brought to its most perfect stage of development by Beethoven. Not only did he determine the constitution of the orchestra and expand and elaborate the existing features of the different movements (see Beethoven, Vol. II. p. 40), but to all this he added in his subject-matter a depth of human emotion such as hitherto had never come within the scope of musical expression. The essential qualities of his music are nobility of thought allied to perfection of detail, and a true balance between material and form. The *Eroica*, C minor, and A major stand as the most perfect examples of the classical symphony, and also mark the close of the classical period. For, as the perfection of the symphony was due to the increased value of the subject-matter, it was natural when the emotional domain of music became still more extended that composers should find themselves somewhat circumscribed by the limitations of the old form. Beethoven himself is an instance of this, for in the 9th Symphony he substitutes for the usual *finale* an elaborate choral setting of one of Schiller's odes. Succeeding writers have mostly

aimed at a compromise between their poetical instincts and their regard for conventional rule. Among such may be mentioned Schubert, Spohr, Berlioz, Raff, and Schumann, the work of the last being the most important. Mendelssohn was content with the true classical form. The same may be said of Brahms, who, however, has enriched it with so many interesting and characteristic features as to constitute an important departure. See the article by Dr C. Hubert H. Parry in Grove's *Dictionary of Music*.

Symptoms. See DIAGNOSIS, MEDICINE.

Synagogue (Gr. *synagōgē*, 'assembly,' or 'place of assembly,' answering to Heb. *keneseth* or *beth-hakkeneseth*), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, through Ezra's instrumentality, the ancient order of things was restored in Judea, synagogues were established in all the towns for the benefit of those who could not take part oftener than three times a year in the worship of the temple at Jerusalem, and a special ritual of readings and prayers was instituted. From the time of the Maccabees we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; there were short services also on Mondays and Thursdays; and the synagogues contributed more than anything else to the people's steadfast adherence to their religion and liberty. At the same time they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Erected out of the common funds or free gifts of the community, the synagogue had also to be supported by taxes and donations. All profane doings were strictly prohibited in it; even as to dress the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle; the faces of the congregation were turned towards Jerusalem. At the extreme eastern end was the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. Not far from this was suspended the ever-burning lamp. On a raised platform in the middle of the synagogue was the place of the reader or preacher. The women sat separated from the men by a low partition. The affairs of the synagogue were administered by a board of 'ancients' or 'elders,' at whose head stood a chief or principal (*Rôsh hakkeneseth*; Gr. *archisynagogos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. There was an officiating minister (*sheliach tzibbur*), whose office it was to recite the prayers aloud. The beadle, or *chazzan* (sometimes translated 'minister'), had the general charge of the sacred place and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the week-days he had to teach the children of the town or village. This name of chazzan, however, at a later period came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons collected and distributed the alms. It need hardly be pointed out that the organisation, rites, and modes of worship of the Christian church in many respects closely resembled, if they were not modelled on, those of the synagogue.

'The Great Synagogue' (*keneseth haggedolah*) was long the current name for an assembly or synod, supposed to have been founded and presided over by Ezra, consisting of 120 men, said to have been engaged in remodelling the national and religious institutions of the Jews after the return from Babylon. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence completely, or, with Kuenen, to identify it with the temporary convocation of the people recorded in Nehemiah viii. It is, however, certain that Ezra and Nehemiah did a certain amount of work which they could not have done without being assisted by eminent collaborators. It was probably this body, however constituted, to which certain vital ameliorations in the administration of justice are ascribed; they developed public instruction, fixed and enlarged the Mosaic laws by certain rules of interpretation, and, according to the tradition, collected and redacted the sacred books.

See the articles JEWS, SANHEDRIM, RABBI; and Schürer's *History of the Jewish People in the Time of Christ* (Eng. trans. 5 vols. 1886–90).

Syncline. See ANTICLINE.

Syncope. See FAINTING.

Syncretism, a term derived from the habit attributed to the ancient Cretans of fighting fiercely amongst themselves, but combining resolutely against common external enemies, came to be used of theological compromise—between Catholics and Protestants, between Lutherans and Reformed. But the great syncretistic controversy was within the pale of the Lutheran Church, syncretism being applied by the High Lutheran party headed by Calovius to the principles of Calixtus and his school. Calixtus and the university of Helmstädt were held so far from Lutheran orthodoxy in the direction of the Calvinist theology as to be little better, or even rather worse, than the Reformed leaders themselves. The bitterness and rancour of the controversy were incredible, and were maintained with short truces till the death of Calovius (q.v.). See also CALIXTUS.

Syndic (Gr. *syn*, 'with,' and *dikē*, 'justice'), a name which has at different times and in different countries been given to various municipal and other officers. The accredited legal representative of a corporation, society, or company was in many cases designated by this title. In Geneva the chief-magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents; the various trading companies in Paris and the university had also their syndics; and in the university of Cambridge the name is still applied to special committees of the senate.

Syndicate in the commercial world is used to indicate an association of merchants or others for the purpose of carrying through some great or important enterprise, or for securing a kind of artificial monopoly in the production or supply of some commodity. See MONOPOLY, STOCK-EXCHANGE, and the *Contemporary Review*, March 1899.

Synergism (Gr. *syn*, 'together,' and *ergon*, 'work'), that deviation from the Augustinianism of Luther and the first stage of the Reformation which was regarded as a form of Semi-Pelagianism (see PELAGIUS). Melanchthon, who latterly taught expressly that the human will has 'the power of seeking grace,' and that in the work of grace there is co-operation between the Holy Spirit and man's will, was the chief representative of synergism.

Synesius, Bishop of Ptolemais in the Libyan Pentapolis, acted also the various parts of soldier,

diplomatist, orator, philosopher, and poet. Born at Cyrene about 375 A.D., the contemporary of Augustine, he took pride in tracing his descent from the Heraclidæ, the royal family of Sparta, who first colonised the Pentapolis, and inherited wealth and estates in the interior. He studied at Alexandria under Hypatia (q.v.), whose influence over him proved a dominant and lifelong one. He used to turn to her for advice when in difficulty, and for sympathy when in trouble. He also studied in Athens, which disappointed him; and he returned to the Pentapolis, resolved to spend his life in study and in the pursuits of a country gentleman. Of hunting in particular he was passionately fond. About 399 he was appointed by his fellow-citizens a delegate from Cyrene to bring certain grievances before the Emperor Arcadius at Constantinople. He remained in that city for three years. In his speech 'On Kingship' Synesius warns Arcadius sternly of the perilous nature of the times, and points out the duties of a good king. During his stay at Constantinople a revolution took place, Arcadius was driven out by the Scythian general Gainas, and Aurelian, leader of the national party, banished. While waiting for an audience Synesius wrote a curious book entitled *Concerning Providence*. In the form of an allegory he describes the contest between Aurelian and Gainas, under the veil of a conflict between Osiris and Typhon, who personify Good and Evil; and deals with the question why God permits evil, and delays so long to interfere. In a few weeks Gainas fell, Synesius attained the end of his mission, and sailed for home. The voyage from Alexandria was a perilous one, which Synesius describes in a long and delightful letter. The next eight years were a time of peace and happiness for Synesius; 'books and the chase,' he writes, 'make up my life.' About 403 he married a wife belonging to Alexandria. During these years he wrote his treatise *Concerning Dreams*, a half-burlesque essay, *The Praise of Baldness* (he was bald himself), his *Dion, or on Self-discipline*, setting forth his ideal of the philosopher, the second part of his book on Providence, several *Hymns*, and a great many letters. This peaceful period was interrupted by war. The Libyan nomads made raids upon the fertile Pentapolis; there were no soldiers at Cyrene, but Synesius raised a troop of volunteers. The helpless governor Cerealius fled; Cyrene was besieged, and Synesius had to organise and direct the defence of the city.

Up to this time Synesius appears before us as a man of letters, steeped in Greek literature and philosophy, and standing quite outside of Christianity. Doubtless the horrors of war and barbarian invasion forced upon his mind the weakness of Neoplatonism. In 409 the people of Ptolemais, fearing the appointment of a corrupt governor, fixed on Synesius as their bishop. Synesius was most unwilling; in *Ep.* 105 he tells his difficulties and scruples; but at last he yielded, and was consecrated at Alexandria in 410. From this time to his death his life was burdened and weighed down by constant private troubles and public calamities. On his return to Ptolemais he found the new governor Andronicus playing the tyrant, boldly excommunicated him, and secured his recall. As a bishop Synesius acted with great prudence and decision, yet his conscience troubled him, and he felt he had been presumptuous in undertaking such an office. The Ausurians invaded the country, and Synesius had again to spend his nights on the ramparts and direct the defence. His only surviving child died. Synesius was broken with troubles, and both his philosophy and his religion appeared to fail him in his need. The city was relieved, but he fell ill; and about 413 he died. His last letter was written to Hypatia, who retained all his old affection and reverence. His last *Hymn*, with its humble prayer for deliverance from indwelling sin, contrasts strongly with the Neoplatonic doctrines of the earlier hymns. Hypatia's name for him, 'the good of other people,' indicates the unselfishness of his nature. His 156 letters reveal to us a character fascinating in many ways, a man open-eyed, of high spirit and awake to every call of duty, sound and healthy in body and mind, passionately fond at the same time of intellectual pursuits and of sport, not without vanity, but with no sensual element. In many ways he reminds us of Charles Kingsley. The *Hymns* show Synesius as the poet of Neoplatonism; their keynote is the longing of the soul to rise to intellectual communion with God.

See editions by Turnebus (1553), Migne (text inaccurate; 1859), German trans. by Krabinger, accompanied by revised text and notes (1825–50), and books on Synesius by Druon, *Sur la Vie et les Œuvres de Synesius* (1859), and Volkmann (1869). In T. R. Halcomb's article (Dr Smith's *Dictionary of Christian Biography*) his philosophical and religious belief, and in Miss A. Gardner's book (S.P.C.K., 1886) his relation to the history of the time, are excellently described.

Synod. See COUNCIL, PRESBYTERIANISM.

Synovial Membrane, which facilitates the gliding of a tendon of a muscle or of the integument over a projection of bone; see JOINTS, p. 350.

Synthesis (Gr. *synthesis*, 'a putting together'), in Chemistry, is a term applied, in contrast to Analysis (q.v.), to the building up of compound substances from the elements they contain or from other compounds usually of less complexity than themselves. The term was formerly applied more particularly to the 'artificial' formation by the ordinary processes of the laboratory of substances which were at one time only obtainable as themselves products of the vital processes of plants or animals, or as derivatives from such products. Later the term was especially applied to the building up of complex carbon compounds; the greater part of modern organic chemistry consisting of such synthesis of new compounds of carbon. In the latest work on the synthetical methods for the preparation of organic compounds (that by Elbs, see below) the signification of the term has been still further restricted by the author (quite arbitrarily, however) to those operations only which give rise to compounds resulting from a new union of carbon with carbon.

Syntheses of new organic compounds are frequently the result of chance discoveries of new reactions, but a very large number of such reactions of more or less general applicability have been studied and classified, so that a new synthesis may be the result of a deliberate attempt to produce a new compound of a definite composition. Similarly the constitution of an important compound occurring in nature, such as, for instance, an alkaloid, is often known with tolerable certainty from the products yielded by it in a series of decompositions, and the information which has been gained from these decompositions indicates the lines upon which an attempt at synthesis may be made with a fair prospect of success. The mode of procedure indicated in the foregoing sentence has resulted in the synthetical or artificial production of numerous substances useful in the arts, in medicine, for domestic purposes, &c. As instances of substances naturally occurring in, or obtainable from, plants or animals, which have also been prepared synthetically, the following may be mentioned: indigo; alizarine, the colouring matter from madder; vanilline, the flavouring principle of the vanilla pods; citric acid, the acid of lemons; urea; uric acid, &c. Amongst the most

familiar of synthetically prepared compounds not known as occurring naturally are a large number of the so-called coal-tar colours, saccharine, and many other coal-tar products, &c.

For further information, any large text-book of chemistry may be consulted; for instance, Roscoe and Schorlemmer's *Treatise on Chemistry*. Special works on organic synthesis are Lellmann's *Principien der organischen Synthese* (1887) and Elbs's *Synthetische Darstellungsmethoden der Kohlenstoff-verbindungen* (1889-91).

Syntonin (also called Muscle Fibrin), a substance akin to fibrin, which is an important constituent of muscular tissue. See MUSCLE, p. 354, FIBRIN, PROTEIDS, and ANIMAL CHEMISTRY.

Syphilis is a markedly contagious, infective, and inoculable disease. It gains entrance at a wounded spot, and from thence gradually infects the body. It may manifest itself during the whole of the patient's life, and is capable of being transmitted to the offspring. It has many analogies with the exanthemata, and may be regarded as one of the most important of that group. Syphilis (other than hereditary) can only be propagated by direct contagion or by the transmission of the virus through some vessel or medium which has recently been contaminated. It is most commonly caused by impure sexual intercourse. As the result of this, after a symptomless incubation period of about three weeks, there forms at the point of infection a single painless ulcer, with a hard cartilaginous base and scanty secretion known as the *Primary Sore—Hard Chancre.*—Associated with this a change is seen in the nearest glands into which the lymphatics of the ulcerated spot discharge, and this change extends to all the lymphatic glands of the body. They are enlarged, bullet-like, painless, and do not become matted together as in ordinary inflammations. The sore and glandular enlargement constitute the *primary stage* of syphilis, and last from the date of inoculation for about eight weeks. This is followed by the *secondary stage.* It may be preceded by malaise, headache, and fever, and is characterised by skin eruptions, variable in kind and duration, which are symmetrical, do not itch, fade, and leave no trace. Amongst the first is a brownish-pink evanescent mottling—*Roseola*—on the chest, abdomen, and flanks. This is succeeded by a papular rash, which in its turn frequently assumes a more scaly appearance—*Psoriasis.* Similar changes are seen in the mouth, on the tongue, and about the anus, in the form of mucous patches, cracks, fissures, shallow ulcers, and condylomata. The hair is frequently shed, and crusts form on the scalp. Syphilitic inflammations of the eye (*Iritis*), ear, testes, and periosteum also occur.

The secondary symptoms go on for about a couple of years, become more irregular in duration and character, and gradually cease as the period of the *tertiary stage* develops. This may show itself long after the cessation of secondary symptoms. The disease is no longer contagious, but the lesions which arise are much more serious to the patient. Masses of cells of low vitality, known as gummata, non-vascular, with a pronounced tendency to break down and ulcerate, may arise in any of the tissues. They are asymmetrical and are specially prone to affect the connective tissue, skin, bone, muscle, and viscera. They frequently simulate malignant tumours, and are a fertile source of many of the diseases of the brain and spinal cord, giving rise to epilepsy and various forms of paralysis. In some instances tertiary syphilis is lifelong, and resists treatment most obstinately.

The precise nature of the syphilitic virus is at present unknown. There is reason to believe that a micro-organism similar to that of tubercle is the cause. This would seem to proliferate in the primary sore, to be carried along the lymphatics, and so to infect the whole of the tissues. Attempts to excise the sore have not met with success in preventing the disease. Syphilis is one of the most frequent causes of abortion, and the infants of syphilitic parents show the manifestations of secondary syphilis in the form of skin eruptions. In more advanced life hereditary syphilis is recognised amongst other things by the irregular and peg-shaped teeth, the depressed broken-like nose, and traces of inflammation of the cornea. It is noteworthy that the mother sometimes displays no evidence of the trouble, her children cannot infect her, while they may readily infect their nurse and other healthy people with whom they are brought in contact.

The treatment of syphilis requires that one should aid the elimination of the disease, combat the anæmia caused by it, antagonise the tendency to the formation of gummata, and prevent the spread of the infection. It is necessary to warn the patient that during the whole of the primary and secondary stages he is a cause of danger to others, and that, while his normal evacuations are innocent, the discharges from any sore or abraded surface and his blood are most virulent. Hence the utmost care must be taken to avoid contagion through the medium of the utensils he uses at meal-time, &c. He should lead a regular life, taking due exercise and avoiding strains and excess of all kinds. The anæmia and the syphilitic virus itself are met by the administration of mercury. This should be given in small doses over a prolonged period, say of twelve to eighteen months, with frequent short breaks. By this means the secondary symptoms are alleviated, and the tertiary stage may be prevented.

In later secondary eruptions iodide of potassium may be combined with the mercury, and in tertiary conditions the iodide alone is indicated. Large doses of iodide—10 or 15 grains thrice a day—are frequently required in cerebral and spinal syphilis. The patient who suffers from syphilis should not be allowed to marry until he has passed six months without showing any evidence of secondary mischief, and that too without taking mercury. At least two years should have elapsed since he contracted the disease.

In the event of a mother producing syphilitic children she alone should be allowed to nurse them. As a rule syphilis is very amenable to treatment, provided the patient be otherwise strong and leads a regular life. Syphilis is a disease of remote antiquity, and is found all over the globe. It is now probably becoming much milder in its effects, although occasionally local outbreaks do occur which display all the malignancy which characterised it during the middle ages.

The extraordinary prevalence of this disease during the latter part of the 15th century led to the unfounded belief that it had come from the New World with the Spanish navigators, though the name *Morbus Gallicus*, or the Neapolitan Disease, was that now commonly given. It seems probable that at an earlier date, when its cause had not been recognised, it was often confounded with other diseases, such as leprosy. The word was borrowed from the name of a hero in Fracastoro's poem *Syphilidis Libri III.* For its history and treatment (including *Syphilisation*, a suggested method of securing a mild form of the illness and subsequent prevention by inoculation), see Häser, *Geschichte des Medicins;* Rosenbaum, *Die Lustseuche im Altertum* (1888); and the Manuals by Lancereaux (1869), Lee (1875), Cooper (1884), Hutchinson (1887), and Von Zeissl (New York, 1887).

Syra (Gr. *Syros*), the most important, though not the largest of that group of islands in the Ægean Sea known as the Cyclades (see GREECE). It is about 10 miles long by 5 broad, has an area of 42½ sq. m., and is bare, rocky, and not very

fertile. Its prosperity is of quite modern growth. During the War of Independence Syra remained neutral, hence many fugitives of commercial enterprise flocked thither from Chios and other parts of Greece. Pop. of island, 33,000. The capital, *Syra*, or *Hermoupolis* (pop. 23,000), is situated on a bay on the east side of the island. It rises terrace-wise from the shore, is well built, and is the seat of government for the Cyclades, and the seat of a Roman Catholic bishop. This port is the chief commercial entrepôt of the Ægean. Every year it imports, principally manufactured wares (one-third of total), hides, grain and flour, yarns, timber, iron, salt-fish, rice, and coal to the average valne of £1,210,500 (£685,650 supplied by Great Britain), and exports tobacco, emery-stone, valonia, sponges, and fresh vegetables to the average valne of £103,280.

Syracuse, anciently a famous city of Sicily, situated on the south-eastern coast of the island, 80 miles SSW. of Messina, was founded by Corinthian settlers about 733 B.C. The colonists seem to have occupied the little isle of Ortygia, which stretches south-east from the shore. The settlement rapidly rose to prosperity, and towards the end of the 6th century B.C. sent out colonies of its own. Little is known of the early political state of Syracuse; but about 485 the ruling families, probably descendants of the original colonists, were expelled by the lower classes of citizens. Gelon (q.v.), despot of Gela, restored the exiles, and at the same time made himself master of Syracuse. He increased both the population and the power of his new state, and won the highest prestige by a great victory over the Carthaginians at Himera. In his time Achradina, a triangular tableland north of Ortygia and on the adjoining mainland, was built upon. This ultimately became the most extensive and populous quarter: it contained the Agora, a temple of Zens Olympius, the Prytaneum, with a splendid statue of Sappho and fine monuments to Timoleon and the elder Dionysius (q.v.), &c. At a later date, and possibly thus early, there were two other quarters in the city—Tyche, occupying a plateau to the west of Achradina; and Neapolis (New City), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the Great Harbour, a spacious and well-sheltered bay to the south-west of Ortygia. This islet, however, contained the citadel, which overlooked the docks in the Lesser Harbour on the north.

Hiero (q.v.), the successor of Gelon, was celebrated throughout the Greek world as a patron of the fine arts and of men of genius, as Æschylus, Pindar, &c. In 467 B.C. the democracy again got the upper hand—Thrasybulus, Hiero's brother and successor, a 'tyrant' of the baser sort, being expelled; and for sixty years a free and democratic government was enjoyed, under which Syracuse flourished more than it had ever done. During this period occurred the great struggle with Athens (415–414 B.C.), and the celebrated siege by the Athenian armament, a contest in which the Sicilian city came off victorious. Nine years later Dionysius (q.v.) restored the 'tyranny' of Gelon, and during a reign of nearly forty years greatly increased the strength and importance of the city (see SICILY). It was he who constructed the docks in the Greater and Lesser Harbours, and surrounded the city with fortifications. His fierce war with Carthage (397 B.C.) raised the renown of Syracuse still higher. The reigns of the younger Dionysius (q.v.) and of Dion, the friend of Plato, were unsettled; but after the restoration of public liberty by Timoleon (343 B.C.) a brief season of tranquillity ensued. In 317 B.C., twenty years after the death of the noble Timoleon, Agathocles, a rude soldier of fortune, once more restored the despotic form of government, which continued, with scarcely an interruption, through the reign (fifty years) of the enlightened Hiero II., the friend and ally of Rome, down to the conquest of the city by the Romans after a siege of two years, in which Archimedes perished (212 B.C.). This event was occasioned during the Hannibalic war by Hieronymus, a rash and vain young man, abandoning the prudent policy of his grandfather, Hiero (q.v.), breaking the alliance with Rome, and joining his and their foes, the Carthaginians. Under the Romans Syracuse slowly declined, though with its handsome public buildings and its artistic and intellectual culture, it always continued to be the first city of Sicily. It was captured, pillaged, and burned by the Saracens in 878 A.D., and after that sunk into complete decay. For ancient Syracuse, see Freeman's *History of Sicily*.

The modern city (*Siracusa*) is confined to the original limits, Ortygia, which, however, is no longer an island, but a peninsula. The streets, which are defended by walls and a citadel, are, with few exceptions, narrow and dirty. Syracuse has a cathedral (the ancient temple of Minerva), a museum of classical antiquities, a public library, with some curious MSS., numerous churches, monasteries, and nunneries, the ancient fountain of Arethusa (its waters mingled with sea-water since the earthquake of 1170), and remains of ancient Greek and Roman temples, aqueducts, the citadel Euryalus, a theatre, an amphitheatre, and quarries, besides ancient Christian catacombs. The people manufacture chemicals and pottery, and trade in fruits, olive-oil, wine (exports), wheat, timber, and petroleum (imports) to the annual value of a quarter of a million sterling. Pop. 19,389.

Syracuse, an important city of central New York, seat of Onondaga county, lies in the beautiful Onondaga valley, stretching along Onondaga Creek to the head of the lake of the same name. It is on the Erie Canal, and is a terminus of the Oswego Canal; by rail it is 148½ miles E. of Buffalo and 147½ W. of Albany. Syracuse is the seat of a Methodist Episcopal university (1870), open to both sexes. It carries on extensive manufactures, the most notable being salt, of which some 6,000,000 bushels annually is produced. The city possesses rolling-mills, Bessemer steel-works, foundries, blast-furnaces, boiler-factories, and manufactories of engines, farming implements, furniture, doors and blinds, picture-frames, silver-ware, musical instruments, saddlery, boots and shoes, flour, beer, &c. The salt-springs were visited by French missionaries as early as 1654, and began to be worked by white men in 1789; the city was incorporated in 1847. Pop. (1880) 51,792; (1890) 88,143.

Syr-Daria. See JAXARTES.

Syria, a country of western Asia, embracing the regions that lie between the Levant and the Euphrates from Mount Taurus in the north to the southern border of Palestine, or even to the peninsula of Sinai. The eastern boundaries south of the Euphrates are not clearly defined or marked off from the wide expanse of the Arabian desert. The physical conformation of Syria is throughout simple and uniform. A range of mountains, split in the north into two parallel chains—Libanus and Anti-Libanus—fronts the Mediterranean, ranging in height from 6000 feet in the north up to 10,000 feet in the central parts, but falling again in the south to 3500 feet. Behind these mountains lies a tableland, that gradually falls away eastwards to the desert. The separate districts of Syria have

been already described in geographical detail in the articles LEBANON, PALESTINE, PHŒNICIA, BASHAN, HAURAN, DEAD SEA, JORDAN. The prevailing winds being westerly, the slopes of the mountains next the Mediterranean and the valleys ensconced among them, together with the immediate seaboard, get a tolerably plentiful supply of moisture during the rainy half of the year (October to May); snow even falls on the highest summits of the mountain-ranges. The climate on the platean is generally dry, and in certain localities hot. The valley of the Jordan is remarkably hot. The soil is in many parts possessed of good fertility, and in ancient times, when irrigation was more extensively practised, yielded a much greater return than it does at the present time. Damascus is noted for its gardens and orchards. Hauran produces excellent wheat. Northern Syria is the home of the olive. The vine grows in nearly all parts of the country. Fruit (oranges, figs, &c.) is cultivated on the coast plains. Sheep and goats are the most important of the domestic animals. The principal exports are silk (£405,000 to £665,000 annually), cereals (£150,000 to £300,000), wool, olive-oil, lemons and oranges, soap, sponges, sesame, liquorice, cottons, and tobacco. The total value is about 1 to 1¼ million pounds sterling. The imports reach pretty nearly the same figure; but all the statistics affecting Syria are very imperfect. Manchester goods (£768,000 to £944,000) constitute the chief item in the imports. Besides these there are woollens, rice, copper and iron, sacking, timber, and hides. The chief port is Beyrout, and to it must be added Acre, Caiffa (Haifa), Tyre, and Tripoli. Railways, to connect Damascus with Acre and with Beyrout, and Tripoli with the interior, are projected. The population is estimated at 2,677,000 and at 1,450,000, and again at about 2,000,000. The bulk of the inhabitants are Mohammedans, but do not all profess the orthodox Sunnite creed: for instance, there are the Druses (q.v.), certain sects of Shiites, and others. The Christians make up about one-fifth of the total (see below). The principal ethnic elements in the population are descendants of the ancient Syrians (Aramæans) and Arabs, these last both settled and nomad; besides there are Jews, Turks, and Europeans.

The earliest historical records that treat of Syria are those that relate the histories of the Hittites (q.v.), the Phœnicians (q.v.), and the Hebrews (see JEWS). The first named were for several centuries supreme in northern Syria, and at times stretched their authority southwards as far as the hills of southern Palestine. Yet they had most formidable rivals on both sides of them in Assyria and Egypt, from both of which countries their subjects derived no small share of their skill in manufacturing industry, and in the arts and manners of life. The other two peoples mentioned occupied the most prominent place in southern Syria. Nevertheless at different periods we read of flourishing Aramæan (Semitic) principalities, such as Damascus, Hamath, Zobah, and similar petty states. These, as well as most of northern Syria, were conquered during the 8th century B.C. by the kings of Assyria; the Jewish kingdoms experienced the same fate at the hands of the Babylonian kings in the 7th and 6th centuries. As previous to the 9th century B.C. Syria had been the battle-ground of the Egyptian and Hittite armies, so after that period it was, as a province of Assyria (Babylonia), involved in the struggle between that great empire and Egypt. (The Greeks first knew this region as a province of Assyria; hence the contracted name Syria.) Towards the end of the 6th century B.C. Syria fell under the dominion of the Persian empire; and two centuries later it was conquered by Alexander of Macedon. When his empire broke to pieces the Seleucidæ (q.v.) made Antioch the capital of their empire of Syria. From the Seleucidæ it passed, through the hands of Tigranes of Armenia, to the Romans, for whom it was won by Pompey in 64 B.C. Under these new masters the country flourished and became celebrated for its thriving industries, its commercial prosperity, and its architectural magnificence (see BAALBEK, PALMYRA; also NABATÆANS). On the division of the Roman world Syria became part of the Byzantine empire, and of it remained a province until its conquest by the Mohammedan Arabs in 636. It still continued to be prosperous under the Arabs and their successors the Egyptian sovereigns, in spite of the unsettled period of the Crusades (q.v.). The first severe blow it suffered came from the Mongols in 1260, and its ruin was completed when in 1516 it passed from the Egyptians to the Ottoman Turks, its present rulers.

See Burton and Drake, *Unexplored Syria* (2 vols. Lond. 1872); Lady Burton, *Inner Life of Syria* (1875); Von Südenhorst, *Syrien und seine Bedeutung für den Welthandel* (Vienna, 1873); Lortet, *La Syrie d'Aujourd'hui* (Paris, 1884); Baedeker's *Palestine and Syria* (by Professor A. Socin); C. R. Conder, *Heth and Moab* (1883); De Vogué, *Syrie Centrale; Architecture Civile et Religieuse du 1er au 7me Siècle* (Paris, 1865–77); and books quoted under the various articles cited above.

The *Church of the Syrian Rite* was that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch and (after that of Jerusalem obtained a distinct jurisdiction) partly in the patriarchate of Jerusalem. The Syrian Church of the early centuries was exceedingly flourishing; before the end of the 4th century it numbered 119 distinct sees, with a Christian population of several millions. The first blow to its prosperity was the fatal division which arose from the controversies on the incarnation (see EUTYCHES; GREEK CHURCH, Vol. V. pp. 397–399). The Eutychian heresy, in one or other of its forms, obtained wide extension in Syria; the Moslem conquest accelerated the ruin thus begun; and from the 7th century downwards this once flourishing church declined into a weak and spiritless community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of its utterly fallen and contemptible condition. In Syria there are now, beside the dominant Moslems and the Druses (q.v.), Orthodox Greeks, United Greeks, United Syrians, and Maronites (q.v.)—the three latter in communion with the Roman Catholic Church (q.v.), besides Protestant missions. See also NESTORIANS; THOMAS (CHRISTIANS OF ST); LITURGY (p. 661); SEMITIC LANGUAGES; BIBLE (p. 126); and O. H. Parry, *Six Months in a Syrian Monastery* (1895).

Syringe (Gr. *syrinx*, 'a pipe'), a hydraulic instrument, consisting of a cylinder of metal or glass, having a conical nozzle at one end, and the other fitted with an air-tight piston. The nozzle being inserted in a liquid, the retraction of the piston draws the liquid into the cylinder, on the principle of the Pump (q.v.), and by its forward pressure the liquid is expelled from the nozzle in the form of a jet. See CLYSTER.

Syrtis, the ancient name of two gulfs of the Mediterranean Sea, on the north coast of Africa. The Syrtis Major, now called the Gulf of Sidra, lies between Tripoli and the tableland of Barca, and forms the most southern part of the Mediterranean. The Syrtis Minor, now called the Gulf of Cabes, lies between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands.

Syrup (Fr. *syrop*, Span. *xarope*, Arab. *shurâb*, 'a beverage,' 'wine,' 'syrup.' *Shrub* is a doublet; and *sherbet*, Arab. *sharbât*, is from the same root), in its simplest meaning, a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar and many flavoured liquids, treated in the same way. Generally speaking, the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the Continent to mingle with water for drink, and are very wholesome. The 'golden syrup' of the grocer is the uncrystallisable finally separated in the manufacture from crystallised sugar (see SUGAR). Medicinal syrups contain with the sugary element some therapeutic agent. Parrish's Syrup contains the phosphate of iron with the phosphates of lime, potash, and soda, dissolved in dilute phosphoric acid, sugar being added. Easton's Syrup has in it phosphate of iron, with the phosphates of quinine and strychnine. There are syrups of the hypophosphites, and many others.

Syrus, EPHRAEM. See EPHRAEM SYRUS.

Syrus, PUBLIUS or PUBLILIUS, a Roman writer of mimes who flourished about 43 B.C., and was most probably a Syrian slave brought to Rome in early youth, educated, and freed by some indulgent master. After Laberius he reigned supreme on the stage, and his mimes, being as full of shrewd epigrammatic wit as broad humour, did not altogether perish with him. About two hundred apophthegms are still extant, under the title *Publilii Syri Mimi Sententiæ*. One of these supplied the motto for the *Edinburgh Review*, although Sydney Smith admits that none of the young collaborators knew anything further of its author: 'Judex damnatur cum nocens absolvitur.'

Syzran, a town of Central Russia, a few miles from the right bank of the Volga, and 90 miles S. of Simbirsk. Laid out in 1685, it has tanneries and noted market-gardens, and a large trade in grain, timber, salt, and manufactured goods. Pop. 28,624.

Syzygy (Gr. *syzygia*), a term used indifferently either for the Conjunction (q.v.) or opposition of the moon.

Szabadka, or MARIA-THERESIOPEL, a royal free town of Hungary, stands on the plain that lies between the Danube and the Theiss, 106 miles S. by E. of Budapest by rail, and is the centre of a rich agricultural district, with a trade in cattle, skins, wool, corn, fruit, tobacco, &c. Pop. (1881) 61,367; (1890) 73,526.

Szarvas, a town of Hungary, on the river Körös, 80 miles SE. of Budapest. A good breed of horses is cultivated here. Pop. (1890) 24,391, mostly Slovaks, who, however, speak Hungarian.

Szathmar-Nemethy, a town of Hungary, on the Szamos, 68 miles by rail NE. of Debreczin, with a Roman Catholic cathedral, and a trade in wine. Pop. (1890) 20,613.

Sze-chwan, the largest province of China, 185,000 sq. m. in area, is situated in the west, having Tibet on the north-west and Yunnan on the south-west; the remaining boundaries are conterminous with various provinces of China. It is traversed and watered by the Yang-tsze-Kiang and its affluents, is hilly throughout, mountainous in the west, and rich in natural products, including coal, iron, and other minerals. Opium, silk, salt, sugar, medicines, tobacco, hides, musk, rhubarb, and white wax (produced by an insect) are exported to the annual value of £5,000,000; and European cottons and woollens are imported to the value of £3,000,000 annually. The capital is Ching-tu, the chief commercial town Chungking, on the Great River, which was opened to British trade in the end of 1889. Ichang (q.v.) was thrown open to foreign trade in 1877. Pop. (1895) 71,000,000, a prosperous, peaceful, and contented people. See A. Hosie, *Three Years in Western China* (1890).

Szegedin, a royal free town of Hungary, stands at the confluence of the Maros with the Theiss, 118 miles by rail SE. of Budapest. This town was almost completely destroyed by a terrible flood in March 1879, out of 6566 houses 6235 being overwhelmed. Since then it has been rebuilt, and now possesses very handsome public buildings, including a town-house, post-office, law-courts, theatre, barracks, &c., and is protected against inundations by a double ring of embankments. The Theiss is spanned by a couple of railway bridges and a fine suspension bridge (1940 feet long), designed by Eiffel. Szegedin manufactures soap, spirits, matches, soda, tobacco, coarse cloth, &c., and carries on an extensive river-trade in wood, corn, and wool. A speciality of the place is *paprika*, a kind of capsicum. From 1526 to 1686 it was occupied by the Turks. Close by Haynau defeated the Hungarians on 3d August 1849. Pop. (1880) 73,675; (1890) 87,410.

Szenta. See ZENTA.

Szentes, a town of Hungary, 30 miles N. of Szegedin, near the left bank of the Theiss. Pop. (1880) 28,712; (1890) 30,758, chiefly engaged in the wine-culture.

Szolnok, a town of Hungary, on the Theiss, 66 miles by rail E. by S. of Budapest, with a lively trade in tobacco, timber, and salt. Pop. (1880) 18,247; (1890) 20,640.

T

the twentieth letter in our alphabet, is derived from the Greek letter *tau*, which corresponds in position, name, form, and value to the Semitic letter *tau*, a name which denoted the 'sign' or 'cross' used in marking the ownership of cattle. Whether, like most of the other letters, it was derived from the Egyptian hieroglyphics is uncertain. If so it must be referred to the hieroglyphic picture usually called the lasso or noose, but which is probably the picture of a tongue (see ALPHABET). The oldest Semitic forms are ×, which appears in the 9th century B.C. on the Moabite Stone, and †, found about a century earlier in the Baal Lebanon inscription. This earlier form was transmitted to the Greeks unaltered, save that, even in the earliest inscriptions, those from Thera, we have the form ⊤, the vertical stroke not projecting above the horizontal bar. The Romans retained the Greek form of the letter, and it was not till the 12th century A.D. that in the minuscule (t) we have a reversion to the older form.

The sound of *t* is that of the hard dental mute, and is produced by the tip of the tongue being brought into contact with the base of the upper teeth, or, as in *tranee*, with the front of the hard palate. The difference between *d* and *t* is that the first is voiced or soft, and the second voiceless or hard. By Grimm's Law (q.v.) a primitive *t* becomes *th* in Low German and *d* in Old High German. Thus the Latin *tu* and *tres* become *thou* and *three* in English, and *du* and *drei* in German. A primitive *d* becomes *t* in Low German, and *z* in Old High German. Thus the Latin *duo*, *decem*, and *dens* become *two*, *ten*, and *tooth* in English, and *zwei*, *zehn*, and *zahn* in German. A primitive *th* (*dh*) becomes *d* in Low German, and *t* in Old High German. Thus the Greek *thugatēr* is *daughter* in English, and *toehter* in German.

A final *n*, *s*, or *r* often attracts an intrusive *t*, as in the words *tyrant*, *parchment*, *cormorant*, *ancient*, *pheasant*, *against*, *amongst*, *amidst*, *behest*, or *thwart*. A final *t* sometimes disappears, as in *anvil* or *petty*. A *t* followed by *i* or *y* may lapse into the sound of *sh*, as in *nation;* or if followed by *u*, sounded as *iu*, it may become *tsh*, as in *nature*. A final *c* may also become *teh*, as in *thatch* or *watch*. A *t* may become *d*, as has happened with the words *proud*, *bud*, *diamond*, and *eard;* or *d* may become *t*, as in *elot*, *abbot*, and *partridge*. In Latin a *t* is assimilated before *s*, as in *missi* from *mitto*, and at the end of a word only one *s* is retained, thus giving *virtus* for *virtut-s*, *sors* for *sort-s*, or *compos* for *compot-s*. English, Welsh, Spanish, and Greek are the only languages which possess the difficult aspirated sound of *th*. In French loan-words, as *thé* and *théologie*, the *th* is pronounced as *t*, and the same is now the case in German, as in the words *thal*, *thier*, and *thun* (now often spelt *tal*, *tier*, *tun*).

Tabard (most probably, like *tippet*, ultimately from Lat. *tapete*, 'hangings'), a heavy outer coat of rough cloth once worn by poor people; also a loose cloak without sleeves worn by knights over their armour, usually embroidered with their arms —Chaucer's *cote-armour*. The latter use survives in the distinctive coat with short sleeves, worn by heralds and pursuivants, emblazoned with the royal arms.

Tábari, a Moslem historian. See ARABIAN LANGUAGE, Vol. I. p. 365.

Tabasheer, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration. The powder is often chewed with betel in order to renovate the constitution. There are several varieties of tabasheer, one of which, of very rare occurrence, is extremely beautiful, of a delicate azure colour by reflected light, and of a faint yellowish hue by transmitted light, easily crushed between the fingers, and of 'an aerial and unsubstantial texture, which we look for in vain in any other solid.' Other varieties are yellowish, white, and much like some varieties of opal. Tabasheer is very porous, and absorbs water and oil very rapidly; effervescence taking place when it is plunged in water. By absorption of oil the opaque varieties become transparent. When the greater part of the oil is expelled by heat the structure of the tabasheer becomes apparent; it is beautifully veined, the veins being sometimes parallel and sometimes curved. The optical properties of tabasheer are remarkable. Of all known substances it has the lowest refractive power.

Tabernacle (Lat. *tabernaculum*, 'tent'), the portable tent in which the Ark of the Covenant (q.v.) was conveyed, and as such the sanctuary of Israel. It seems (1 Sam. iii. 3) to have been superseded by a more permanent building at Shiloh before David's time. See TEMPLE.—In Roman Catholic churches the name is given to the receptacle in which the consecrated elements of the Eucharist are retained. It is commonly a small structure of marble, metal, or wood, placed over the high altar, and appropriated exclusively to the reservation of the Eucharist, no other object whatever being allowed to be kept in it. See PYX, and the illustration at ALTAR; and for the Feast of Tabernacles, see FESTIVALS.

Tabes Dorsalis. See LOCOMOTOR ATAXIA.

Tabes Mesenterica. See MESENTERY, and TUBERCLE.

Tablature, a method of musical notation, principally employed in the 15th and 16th centuries for the lute, but also used occasionally for other instruments. In tablature the lines of the stave indicate the strings on the instrument, the upper line representing the first string, the second line the second string, &c. The notes are expressed either by Arabic numerals or small letters, which

denote the semitones of the chromatic scale, or the frets at which the fingers ought to be placed to stop the strings—*a* indicating the open string, *b* the first fret, *c* the second fret, and so on. The duration of the sounds is expressed by minims, crotchets, quavers, &c. placed above the stave, over the letter or letters which they are meant to affect, and each of the musical notes is held to apply to the letters immediately following, making them of the same length as the first, until some new note occurs. The method of tuning the lute must be ascertained before any particular tablature can be deciphered, as the pitch of the notes produced by the use of the frets will depend upon that of the open strings. One of the best-known tablatures is that given in the famous Skene manuscript in the possession of the Faculty of Advocates, Edinburgh, written at various times up to 1635.

Tableaux Vivants ('living pictures'), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Madame de Genlis, when she had charge of the education of the children of the Duke of Orleans. They were long common in theatres, as they are now in private circles.

Tablelands, or PLATEAUS, are extensive elevated regions with a plain-like or undulating surface. They may be bordered by steep declivities falling more or less suddenly from the level of the plateaus to the sea or the adjacent low grounds; or they may slope down imperceptibly and thus gradually merge with the lowlands. The tableland of the Spanish Peninsula is a good example of a plateau that rises abruptly from the sea. The 'Great Plain' lying east of the Rocky Mountains, on the other hand, is a plateau that sinks gradually from a height of 6000 feet down to the low prairie lands of the Missouri. Some high tablelands are surrounded by lofty mountains, such as those of Quito, Titicaca, and Uspallata in the Andes, and that of the Pamir in Asia; while others constitute elevated platforms upon which mountain-ranges stand. Two types of tableland are recognised: (*a*) *plateaus of accumulation* and (*b*) *plateaus of denudation*. The former are built up of horizontal or approximately horizontal strata, while the latter are composed of disturbed strata which have been planed down to one general level (see MOUNTAINS). The chief tablelands are in Europe, central Spain; in America, Oregon, the great salt plain of Utah, the north and centre of Brazil; in Africa, the interior of Barbary; while in Asia almost the whole of the south and centre of the continent consists of plateaus, which rise terrace above terrace till they culminate in that of Tibet. Of the Asiatic plateaus the principal are those of Asia Minor (3280 feet above sea-level), Armenia (7000), Persia or Iran (3000), Mysore (4000 to 5000), Deccan (1500 to 2000), Tibet (12,000 to 17,000), and Chinese Tartary (3000 to 4300).

Table Mountain. See CAPETOWN.

Table-turning, a phenomenen attributed, with other more eccentric movements of furniture, to the agency of spirits (see SPIRITUALISM), but practised also in America and Britain from about 1850 as a kind of social pastime; the motion of a table under the finger-tips of a closed circle of 'believers' standing round the edge of the table being referred to a mysterious or occult origin, and not, as by the more sceptical, to the collective but involuntary muscular action of the circle of friends.

Taboga, see PANAMÁ.

Taboo, or TABU, a Polynesian term (probably from *ta*, 'to mark,' and *pu*, expressing intensity) that has supplied a useful verb to the English tongue. The origin of the notion is based on a fundamental religious conception of animistic religion about the natural relations between the gods and certain physical things; it means properly 'sacred,' 'consecrated,' but by a natural transference of meaning by association of ideas has also become equivalent to 'accused,' 'unholy.' The idea of a thing being sacred involves a sense of prohibition, just as a temple or church may be a sanctuary where the safety of a fugitive is respected. And such restrictions enforced by the dread of supernatural penalties become rules of conduct for the regulation of a man's relations to the divine, and thus lead naturally up to ideas of holiness of more advanced religions. Among the Maoris and Polynesians such prohibitions were included within the signification of the word *tabu*, embracing both traditional rules binding on chiefs and people alike, and special prohibitions imposed like the interdict of a modern court of justice, from time to time. Thus the notion could be utilised as a method of protection to life or property—a rudimentary police system and discipline of character, but based upon spiritual even more than on temporal terrors (cf. Judges, xvii. 2). Some things, as idols, the persons and property of chiefs or priests, were always *tabu*, as well as some kinds of food, as the pork denied to women in Hawaii, the water that might not be brought within the house in the Marquesas Islands. Special taboos might be interdicts laid on a house or a road, or an obligation to abstain from some of the ordinary pleasures of life during the sickness of a chief or the time before a battle or a special religious ceremony. This special consecration of the person before battle seems to be fairly made out also as a Semitic custom, by comparing Deut. xxiii. 9–14 with 1 Sam. xxi. 4–6. Again, taboos varied in intensity—during the stricter none went outside his house save the priests, and no fire was lighted. The usual length was forty days, and the fact was intimated by such marks as a white cloth hung up on the thing tabooed. Again, many things were naturally taboo—women after childbirth or menstruation, the bodies of the dead, the head and hair of a chief, and the like—usages which touch the ceremonial uncleanness of Leviticus and some the distinctive characteristics of Nazarites. Elaborate ceremonies were fixed for the removal of the interdict of taboo, and the penalty for its violation was death, in New Zealand usually indiscriminate spoliation of the property of the offender. In New Zealand also there was a development of the system by which a man could reserve something to himself by a kind of private taboo—a system which would readily lend itself to dishonest ends like the *Corban* by means of which unprincipled New Testament Jews wriggled themselves out of their natural obligations. Anything formally devoted or consecrated to a god is inalienable, and contact with it is forbidden under supernatural penalties. Such a ban is merely a taboo, and we find the full significance of such wide-spread restriction in such passages as 1 Kings, xvi. 34; Deut. vii. 26; Josh. vii.; Job, xv. 28. It is obvious that ecclesiastical Excommunication (q.v.) is itself a form of taboo, as also the infamous 17th-century Letters of Intercommuning issued by the Scottish Privy-council against holding any intercourse with the persons therein named, as well as the too notorious boycotting of later days in Ireland.

It only remains to say that a similar distinction between the ceremoniously clean and unclean will be found in the religious rituals of every primitive people. Holy and unclean things are alike in this, that both lay restrictions on man's use of and contact with them, the former because they pertain to the gods, the latter because they are hateful to the

gods and therefore not to be tolerated by their worshippers. Uncleanness is treated like a contagion, to be washed or purified away. The prohibitions against eating certain animals are closely parallel to the taboos which totemism lays on the use of sacred animals as food. Certain garments also become taboo by contact with holy places, and the worshipper must put off his ordinary clothes (1 Sam. xix. 24) or put on special garments (cf. Ex. xix. 10, Gen. xxxv. 2). And herein we may find the key to many such wide-spread phenomena as fasts, special abstinences, periods of continence, injunctions against eating special things or naming certain names.

See the works on Polynesia or New Zealand, by Ellis, Turner, Waitz-Gerland (vol. vi.), Shortland; the admirable article by J. G. Frazer in *Ency. Brit.* (vol. xxiii. 1888), and Notes C and D to Prof. Robertson Smith's *Lectures on the Religion of the Semites* (1889).

Tabor, a dome-shaped, oak-clad hill of northern Palestine, 7 miles E. of Nazareth, rising solitarily in the north-eastern part of the plain of Esdraelon to a height of about 1000 feet. In the 2d century it was regarded as the Mount of Transfiguration, and the ruins of a crusading church on the summit commemorate this event. Tabor is not named in the New Testament.

Tabor, a small drum like a timbrel or tambourine without jingles, usually played with one stick and in combination with a fife.

Taborites. See Huss, Vol. VI. p. 16.

Tabriz (also spelt *Tabreez*, *Tebris*, and *Tavris*), a great and ancient city of Persia, capital of the province of Azerbijan, 40 miles E. of Lake Urumiah, and on the Aji, which flows south-west into that lake. The interesting ruin, Kabúd Masjid, or 'blue mosque' (dating from 1450), is in part covered with blue tiles beautifully arabesqued. The citadel is a spacious edifice of burned brick, the walls of which have been cracked in many places by earthquakes. Tabriz is the seat of a varied industry, in which leather, silk, and gold and silversmith's work alone are notable; it is also the emporium of an extensive transit trade. The imports have been estimated at £750,000 a year, and the exports at £350,000—but there is much smuggling carried on. The chief imports are cotton fabrics, sugar, woollen cloth, and wines and spirits. The chief exports are drugs and spices, dried fruits, shawls, carpets, and raw silk. The opening of the Russian railway between the Black Sea and the Caspian, and Russian tariff legislation have injured the overland trade by Tabriz. The Anglo-Indian telegraph line passes through the city. There has been much debate about the identification of the city with an ancient *Tauris;* it was reputed to have been refounded in 791 by one of the wives of Harûn-al-Rashid. In 858, 1041, 1721, and 1854 it was devastated by earthquakes, and it has been besieged, taken by Turks, Turcomans, and Persians in succession. Pop. 170,000, very many of them Turks, and 3000 Armenians.

Tacahout, an Arab name for the small gall formed on the Tamarisk tree, and used as one source for obtaining Gallic Acid (q.v.).

Tacamahaca. There is a good deal of confusion in botanic and commercial circles as to the trees which produce this resin, for Elemi (q.v.) and other resins are often confounded with it, most of these being produced in Brazil by different species of Icica. The fragrant bitter resin from Brazil is chiefly yielded by *Icica tacamahaca*, but other species, as *I. heptaphylla*, *I. icicariba*, &c., furnish a similar resin, known locally as 'almaceja,' which is used in medicine and the arts, and burned as incense in the churches. One Tacamahaca, from *Elaphium Jacquinanum*, sells in Mexico at a dollar a pound, and is called Caricarilo in Venezuela. *Calophyllum calaba* yields East Indian tacamahaca, which somewhat resembles species of olibanum, and gives off a similar odour when heated. The Mexican tacamahaca is usually called shell-tacamahaca, but is better known as *Elemi*. *Populus balsamifera* is termed the Tacamahac poplar, but it yields little or no resin, the leaf buds only being used in ointments to prevent rancidity.

Tachylite, a black opaque natural glass, which results from the rapid cooling of molten basalt. It occurs as a thin selvage to dykes and veins of intrusive basalt—the latter having cooled rapidly from contact with the adjacent rocks. In Hawaii it appears as a scoriaceous or a compact crust, 2 inches or less in thickness, upon the basic lavas of that region. Tachylite never forms lava-flows like the acidic glasses (Obsidian). See Basalt.

Tacitus, the historian, is known to us chiefly from autobiographical touches in his own writings and from allusions in Pliny's letters. His full name is matter of doubt—Cornelius Tacitus being his nomen and cognomen; but whether his prænomen was Publius or Gaius can only be conjectured. Born perhaps at Rome (less probably at Terni) under the Emperor Claudius between 52 and 54 A.D., we infer that his family was respectable from his education, his profession, and his marriage. He studied rhetoric in Rome under M. Aper, Julius Secundus, and, likely enough, Quintilian; rose to eminence as a pleader at the Roman bar; and in 77 or 78 married the daughter of Agricola, the conqueror and governor of Britain. To this alliance he doubtless owed the accelerated promotion which, beginning with a quæstorship under Vespasian, made him prætor in 88 A.D. and a member of one of the priestly colleges. Next year he left Rome, probably for Germany, where, doubtless as governor, he must have acquired his knowledge of the features, natural and social, of the country; and he did not return till 93, when he found his father-in-law had recently died. We know him to have been an eye-witness of Domitian's reign of terror, almost blaming himself, as a senator, for complicity in that monster's judicial murders of such exemplary citizens as Helvidius and Senecio, and we have his own testimony as to the blessed change wrought by the accession of Nerva and Trajan. Under the former emperor he became consul suffectus, succeeding the great and good Virginius Rufus, on whom he delivered in the senate a splendid *oraison funèbre*. In 99 A.D., conjointly with the younger Pliny, he prosecuted the political malefactor, Marius Priscus, and the 'characteristic dignity' with which his share of the prosecution was conducted won him the thanks of the senate. After this we lose sight of him, but may assume it as certain that he saw the close of Trajan's reign, if not the opening of Hadrian's. The high reputation he enjoyed in life is attested by the eulogistic mention of him repeatedly made in Pliny's letters, and in the third century the Emperor Tacitus, proud to claim kinship with him, built in his honour a tomb which was still standing in the later decades of the 16th century, when it was destroyed by Pope Pius V. The same emperor also issued an edict by which the works of his namesake were to be copied out ten times yearly for presentation to as many public libraries.

In spite of this multiplication of copies we possess but a moiety of what he wrote. His earliest work, the *Dialogus de Oratoribus*, treats, in conversational form, of the decline of eloquence following on the change for the worse in the education of the Roman youth under the empire. This, published in 76 or 77, was for some time suspected to be from

another pen, but is now included in every edition of his works. It has reached us entire. Next comes the *Agricola*, the literary character of which it is difficult to define. Quite a library has accumulated on the question whether it is a 'laudatio funebris,' or an 'apologia' written to shield the memory of Agricola from the charge of servility, or a historical panegyric framed for political ends. As biography it has grave defects, while it cannot be brought under any of the three above-named heads without serious deductions. But it will always be read for its elevation of style, its dramatic force, its invective and its pathos. For English readers its interest is unique. The third work, the *Germania*, or *De situ, moribus, et populis Germaniæ*, is a monograph of the greatest value on the ethnography of Germany. Faulty in geographical detail, it becomes characteristically strong wherever human interest emerges. Fourth in order are the *Historiæ*, or the history of the empire from the accession of Galba in 69 A.D. to the assassination of Domitian in 97. Of the twelve books originally composing it only the first four and a fragment of the fifth are extant. Tacitus is at his strongest in this narrative. His material was drawn from contemporary experience; and though the imperial archives were closed to him, he had at command the personal information open to a man of his position, to say nothing of correspondence (as of Pliny), the 'laudationes funebres,' the 'acta diurna' (what we should call the 'gazette'), and the 'acta Senatus,' the Roman equivalent for Hansard. He had no sympathy with the empire, as indeed we gather from his earliest work. He yearned for the return of an aristocratic oligarchy—the Rome of the Scipios and the Fabii. He is, on this account, a partisan, but is able to justify the most trenchant contrasts between the greatness of Republican and the deterioration of Imperial Rome, which latter he contrasts disadvantageously with the freedom and simplicity of even barbarian Germany. To his peculiar satirical gift which often makes him a 'Juvenal in prose' he gives free rein from time to time; though even in his bitterest moods he never forgets he is a Roman—a certain *chauvinism* betraying itself in his tendency to minimise the defeats of his compatriots and even the number of their slain. He had no appreciation of the higher qualities of the Jews, and his attitude to the growth of Christianity is that of a prejudiced, if cultured Roman, who, recognising an overruling providence or supreme 'Necessitas,' will not stoop to weigh the evidence to which the new religion appealed. The qualities conspicuous in the *Historiæ* are maintained in his last work, the so-called *Annales*, a history of the Julian line from Tiberius to Nero (14 A.D. to 68). Of their sixteen books only eight have come down to us entire, four are fragmentary, and the others lost. In these, as in all his writings, his avowed aim was a noble one, to perpetuate virtue, and to stigmatise baseness whether in word or deed. It is for its direct encouragement of the latter and persecution of the former that he constitutes himself so severe a censor of the imperial system; though he is not blind to the shortcomings of the later republic, under which the provinces, he admits, were worse off than under the empire. Among the more obvious defects which lower his value as a historian are his weakness in geography and his carelessness as to strategic details: he is, as Mommsen calls him, 'the most unmilitary of authors,' though Sallust or Livy run him hard. His style is the most strongly marked of antiquity—statuesque in outline, rich if somewhat too sombre in colouring, effective in antithesis, not seldom obscure from sheer condensation. But the more trouble the reader takes with it the greater his reward.

Editions: Orelli; Ritter; but best of all for the text, Halm; and for the interpretation, Nipperdey and Heräus. English editions are, of the *Annals*, by Frost, but especially that by Furneaux (2 vols. Oxford, 1883–91); of the *Histories*, by Spooner (1891); of the *Germania*, by Furneaux (1895), also by Stephenson and Davis. There is an admirable translation by Church and Brodribb. See also the short studies by Donne (1873), and Church and Brodribb (1881). M. Philippe Fabia in *Les Sources de Tacite* (1895) has sought to prove that Tacitus is overrated, that he makes bad omissions, and that he copies sentence after sentence from older authorities—in the *Histories* from Pliny the elder, in the *Annals* from Aufidius Bassus and Cluvius Rufus.

Tack, a Scots law-term for Lease (q.v.).

Tacna, a southern province of Peru taken possession of by Chili for ten years in 1883 (see PERU, p. 82), but it was not till 1898 that the restoration was finally agreed to on payment of an indemnity by Peru. Area, 8685 sq. m.; pop. (1895) 29,523. Sheep and alpacas are reared, and copper, gold, and silver mined. The capital, Tacna, 38 miles by rail N. of Arica (q.v.), has a pop. of (1895) 9418.

Tacoma, the second city of Washington state, stands on the east side of Puget Sound, by rail 145 miles N. of Portland, Oregon, and 18 S. by W. of Seattle. In 1880 Tacoma was a village with only 1098 inhabitants; in 1890 it was a flourishing city, with trams, cabs, water, gas, and the electric light, miles of wide streets, large wholesale stores, numerous mills and factories, and a busy port. In the district around are coal, iron, precious metals, lumber, farms of wheat, hops, fruit, and vegetables; it has extensive railroad connections, and a trade direct with Japan, forwarding tea to the eastern states by rail. Yet there are traces of the earlier condition of the locality, in the forest close at hand, and in the numbers of Indians seen in the streets from the reservation across the bay. Pop. (1890) 36,006. Behind the city an open valley runs towards where the beautiful volcano Tacoma (or Rainier) rises, from a ridge of snow-covered mountains, to a height of 14,444 feet.

Taconic System, a term applied by Professor Emmons to certain azoic and palæozoic rocks occurring in the state of New York and adjoining districts. These he believed to be the equivalents of the Cambrian rocks of England. Subsequent investigations have shown that Emmons misread the geological structure of the regions studied by him, and his arrangement of the strata has therefore been set aside. The subject has given rise to much discussion amongst American geologists.

Tactics, MILITARY, the science which enables one of two opposing bodies of troops to be stronger than the other at every crisis of an engagement. This may be due to superior numbers, favourable ground, better arms, a higher state of discipline and training, or anything else that, if used to the best advantage, will produce greater strength at the point where and time when it is most essential.

Strategy (q.v.), which has precisely the same objects, merges into tactics as the enemy comes within striking distance, and the latter science is therefore sometimes defined as the strategy of the battlefield. Modern writers use different terms for the various branches of tactical science: *grand tactics* and *manœuvre tactics*, for the marshalling of large masses (30,000 and upwards) of men on the battlefield; *minor tactics*, for the conduct of small bodies, such as advanced and rear guards, outposts, patrols, &c.; *fighting tactics*, for the combat whatever the numbers of the force; *fire tactics*, for the best use of guns and rifles, the massing of their fire, and the selection of the target; and the special *tactics of cavalry, artillery, or infantry, combined tactics, siege tactics*, and *mining tactics*.

It would be impossible to enumerate all the

schemes and devices which go to make up this science, varying as they must with the arms in use and the manœuvring power of the troops employed, but some illustrations may be given from ancient and modern history. In Judges xx. we read of a favourite and dangerous manœuvre, the Israelites feigning to retreat before the Benjamites, so as to draw them on until their flanks and rear were exposed to the 'liers in wait.' Hannibal at Cannæ and William the Conqueror at Hastings were among the many successful imitators of these tactics. Others, like the Duke of Burgundy in 1476 at Granson, lost their armies through attempting it with unsteady troops. Frederick the Great owed his victory at Mollwitz to the rapid fire and steady discipline of his men, and the former was chiefly due to the introduction of iron ramrods. His later battles give us good examples of manœuvre tactics. At Leuthen he engaged the Austrians, immovable in their chosen position, with his advanced guard, while his main body, under cover of some hills and foggy weather, marched in open column of companies round their flank, wheeled into line, and rolled up their army. At Rossbach he showed how to defeat this manœuvre when the enemy put it in practice. Sending his cavalry and artillery to check the head of their marching columns, he threw his main body upon their flank and inflicted a crushing defeat. At Kolin his *linear tactics* failed because the rear of his column wheeled into line too soon, leaving the head to continue the march, so creating a wide gap in the line when formed up. At Waterloo Napoleon showed an example of *combined tactics* on a large scale. By cavalry charges he obliged the British infantry to form squares, which then became targets for his massed artillery. When under stress of this 'hard pounding' they opened out into line, a renewed charge of cavalry obliged them to take the denser formation again. At Gravelotte the German armies (some 240,000 men) showed an unparalleled instance of *grand tactics* by marching to their positions across country in seven large masses, each consisting of one complete army corps. The *minor tactics* employed by advanced or rear guards and outposts are to a certain extent stereotyped. Their object is to prevent the main body—in the first case a column, often several miles long; in the second a large camp, cantonment, or bivouac—from being attacked before it can get into fighting order. Therefore a series of small parties of two to six men lead the way, or stand sentry, some four miles in front of the main body, while larger bodies support them at a little distance, followed in their turn by still larger units, so that the enemy meets with an ever-increasing resistance until he finds himself confronted by the main body drawn up in a carefully chosen position. *Fighting tactics* must depend chiefly upon the arms in use. The mail-clad horsemen of the 15th century never succeeded in defeating the solid phalanx of pikemen opposed to them by the Swiss Confederation until the employment of artillery prevented the latter retaining such a massive formation. The English archer, protected in front by palisades and on the flanks by spearmen, destroyed the chivalry of France at Cressy and Poitiers, but at Bannockburn was ridden down by the Scottish cavalry, because the flanking spearmen had been omitted. Gustavus Adolphus, by employing cartridges, enabled his infantry to fire more quickly than his opponent and so to form on a wider front. The invention of the bayonet, doing away with the necessity for pikemen to protect the musketeers, still further increased the fire-power of infantry. The British two-deep line overthrew, by its enveloping fire and charge, the column formation of the French in the Peninsula and of the Russians at the Alma, though in this battle its defects are shown in the confusion caused by moving to the attack over broken ground. In the battles of the Franco-German war of 1870–71 it was found impossible to advance against the fire of modern breech-loading rifles except by rushes of comparatively thin lines of skirmishers, constantly reinforced by supports and reserves in rear. The magazine rifle and smokeless powder of to-day still further complicate the problem, presented to the assailant, of how to get to within 500 yards of the enemy without being destroyed. No rules can be laid down except that the attacker's first line must move in three portions, skirmishers, supports, and reserves, followed by a second line to assist in the assault, and a third to complete the success or cover a retreat.

In warfare against savages large numbers, fanatical courage, and rapid movements have to be met by special tactics. Thus the crescent-shaped enveloping attack of the Zulus and the rapid attacks of the Soudanese Arabs were received in the impenetrable square formation or by forming 'laagers:' a reproduction of the wagon tactics by which the Hussites of Bohemia defeated the German cavalry in the 15th century, opposing a material obstacle to the onslaught of an enemy unprovided with artillery.

Cavalry tactics, apart from the exceptional use of dismounted men, are much the same as in the time of the Byzantine empire. Cavalry fight by shock action only, and the power of man and horse has not altered. The Byzantine *Turma*, like the British cavalry brigade, attacked in two lines, with a reserve, flanking parties, and reconnoitring groups, manœuvring in column and attacking in line. *Artillery tactics* consist in massing the fire of every gun as soon as possible upon important points, and overwhelming the enemy's guns and infantry with projectiles at ranges of two miles or more, not shunning closer quarters if the necessity arises.

Siege tactics belong to fortification, but follow the same general course as other combined tactics. Thus in defence the guns oblige early deployment and co-operate with the infantry in repelling the advance, while in the attack they destroy the material defences and keep down the fire of the place so as to enable the assault to be delivered. During the siege *mining tactics* (see MINES, MILITARY) will be made use of on both sides. The functions of the cavalry are first to try to drive off the enemy's cavalry and effect reconnaissances on both sides; then on the attacker's side to complete the investment, and afterwards secure the besieging troops against surprise.

Tactics, NAVAL, may be defined as the art of manœuvring ships and fleets for the purposes of battle. Naval strategy, on the other hand, is the science of combining and employing fleets or single ships in order to carry out defined operations at sea or against an enemy's coast, for obtaining command of the sea or certain portions of it. Although fleets had existed and battles at sea been fought from the earliest periods, it was not until towards the close of the 16th century, in the reign of Queen Elizabeth, that naval war began to assume definite form. The discovery of the New World and the occupation of its richest territories by Spain, the opening up of the route to the East Indies by the Cape of Good Hope, and the efforts which English merchants began to make at this time to push their own trade gave a marvellous impetus to the sea-borne commerce of the world, which carried with it as a necessary consequence the building of larger and more seaworthy ships than had previously existed. War at sea at this time does not appear to have been carried on on any definite plan, and consisted principally, if we

except the attempt of the Great Armada, of raids on the enemy's commerce and coast-towns. According to Admiral Colomb, in his excellent work on *Naval Warfare*, the first organised attempts to obtain command of the sea as a distinct aim of the operations carried on are to be found in the three wars between the Dutch and English of 1652, 1665, and 1672. Both parties made desperate attempts to destroy the trade of the other, but in the second war Holland, considering the command of the sea the more important object, temporarily gave up her commerce, Dutch merchant-ships being forbidden to put to sea. The net result of the three wars was to leave the honours pretty evenly divided between the two combatants. Several efforts were made by the French, between 1690 and their crushing defeat at Trafalgar, to obtain the command of the sea in order to effect the invasion of England. The first of these attempts, affording one of the best examples of the value of a thorough grasp of strategical principles, was foiled by the Earl of Torrington. An experienced seaman and profound strategist, the earl was forced against his better judgment, by direct orders from the queen and council, to attack the vastly superior forces under Tourville, and accordingly he gave battle (30th June 1690) off Beachy Head. He was defeated, but skilfully drew off and fell back under shelter of the Gunfleet Shoals at the mouth of the Thames. Here, although 'beaten, inferior, and shut up behind sandbanks,' yet from the strategic position it now held this fleet still remained such a 'power in observation' as to paralyse the action of the victorious and superior force; and the French admiral, after some ineffective attempts at landing, returned to Brest. During the Napoleonic wars, the English fleets having more or less complete command of the sea, the strategy of the commanders seems to have resolved itself into blockade of the enemy where possible, or a close observation of his movements with a view to prevent any junction of his scattered forces; and if he ventured to put to sea, into efforts to bring him to action as soon as possible. Steam may be said to have revolutionised naval strategy and tactics; whereas the best-laid schemes were often frustrated by foul winds and gales, now the great steam-power of battle-ships and cruisers renders them independent of wind and to a great extent of bad weather. As a set-off, however, to this, the coal endurance of ships and the replenishing of their supplies of fuel become important factors in deciding upon their movements. The two principal objects of Great Britain's naval strategy must be the command of the Channel with the seas round her coasts, and the protection of the great trade routes. For this purpose a fleet of battle-ships strong enough to meet any hostile combination, supplemented by a proportionate number of fast cruisers, is indispensable. Neglect to provide an adequate number of both classes of ships would almost certainly land the country in disaster; a deficiency in battle-ships might cause her to lose command of the seas round the coast, and would endanger her very existence as a nation; while a poverty of cruisers would mean a sweeping of the country's trade from the sea—such as happened to the United States during the last great civil war—and deprival of breadstuffs and most of the raw materials required for her manufactures. Eighty per cent. of the sea-borne trade of the world is carried in English bottoms, and a few hostile cruisers, if not immediately hunted down, would in a short time work incalculable havoc, as was proved by the operations of the *Alabama* (q.v.) and other Confederate cruisers. On the question whether blockade is any longer possible the opinions of experts are divided; but the majority hold that blockade has become impossible, or is attended with so many risks as to make it highly inexpedient. The experience gained during the civil war in America and the naval manœuvres of late years would seem to show that a perfectly effective blockade is out of the question; on dark nights or in thick weather vessels will almost certainly be able to slip out unobserved, and the danger of attacks from torpedo boats will prevent the blockading squadron from keeping very close in land. The blockading ships must always have their steam ready for full speed; this entails a large consumption of fuel, and after a few days tubes and fires require cleaning. If this is not done a great falling off of speed is the result; in addition to which allowance must always be made for the absence of ships which are recoaling and readjusting their machinery. The ships blockaded labour under no such disadvantages, and have only to choose their own time for breaking out. Observation of the enemy's ports will therefore probably take the place of blockading; this being carried out by a chain of swift cruisers in touch with the main body of the fleet. The distance at which the main body should remain from the enemy's ports, and whether it should keep the sea or lie at anchor at some favourable base, are questions which the practical experience of war alone can solve. One important factor in favour of Great Britain in a naval war lies in the fact that she holds all the important Coaling Stations (q.v.), now all efficiently fortified.

A more or less formal tactical system in naval battles has existed from a very early period. The triremes or galleys of the ancients were armed with formidable iron or brass beaks; propelled by oars they were formed for attack with their bows pointing to the enemy, the aim being to destroy by an oblique blow the oars on one side of the enemy, and then ram and sink her. The earliest great battle in which the superior tactics of a numerically inferior fleet inflicted a crushing defeat on a vastly superior force was that of Salamis (480 B.C.), between the Greeks and the Persians. According to Æschylus, the Greeks were drawn up in one line, while the Persians were in three, but so crowded together that the ships had not room to manœuvre properly; the attack of the Greeks was so impetuous that the front line of the Persians was driven back, throwing the other two lines into hopeless disorder.

In the battle of Sluys, fought 24th June 1340, the English fleet completely defeated the French. The secret of tactical success is to throw an overwhelming force, if possible, on some point of the enemy's line, and destroy him in detail. And this appears to have been done by King Edward III., who, according to Professor Laughton, successfully manœuvred to bring his line obliquely across the right wing of the French, and completely crushed it. On the 7th October 1571 was fought the celebrated battle of Lepanto, between a combined Christian fleet under Don John of Austria and the Turks, in which the latter were completely defeated, mainly by the skilful tactical arrangements of Don John. Acting under the advice of Don Garcia de Toledo, he divided his fleet into three squadrons, which were formed in line abreast, with sufficient room between each for manœuvring; in rear was a reserve squadron ready to give assistance where required. The bulk of the two fleets was composed of galleys; but the Venetian admiral had with him six galeasses (see GALLEYS), and before the action commenced these were placed about half a mile in advance of the fleet, two in front of each of the three divisions; the fire of these vessels, owing to their heavy ordnance, effectually broke the shock of the Turkish onset. Taking advantage of their confusion, Don John pierced their centre, and the

rout of the Turks was complete, although the commanders of both the Turkish wings displayed considerable tactical skill. The Christian left wing was for a time outflanked and placed between two fires, while the Turkish left wing passed through the Christian line, and, but for the reserve squadron by which it was immediately attacked and driven back, might have altered the fate of the day. Lepanto was the last great battle in which galleys took a prominent part. With 'great ships,' dependent on their sails alone, having their guns mounted on the broadside, a new method of organising fleets for battle came into being. It was not, however, until the wars between the Dutch and English of 1652–72 that the tactical formation of a fleet in 'line of battle' was devised. Previous to this, fighting at sea appears to have been carried on in rather an indiscriminate fashion, although from the first the obtaining of the weather-gauge seems to have been recognised as the great aim for which to manœuvre. Sir W. Monson, a distinguished sea-captain of Queen Elizabeth's time, writes: 'For the greatest advantage in a sea-fight is to get the wind of one another; for he that has the wind is out of danger of being boarded, and has the advantage where to board and how to attempt the enemy.' According to Admiral Colomb, the 'line' was first introduced by the Dutch as a means to weaken the power of fireships, and to bring the fleet under better control. The line of battle consisted in a fleet of ships being extended in a straight line either ahead or abreast one ship of another, keeping as close together as weather permitted, so that at all times every ship should be ready to sustain and relieve one another. It was directed that each ship in the line should keep within half-a-cable's length (about 50 fathoms) of one another. It was introduced into the English navy by Sir William Penn. According to Père Hoste, it was the formation taken up by both English and Dutch in the battle of the 29th July 1653, and by the Duke of York in the battle off the Texel in June 1665. But it was dropped again by Albemarle in the battle of June 1666; and, by the way Sir W. Penn speaks of it (see Pepys), it seems clear that there was still controversy as to whether a line was or was not the best formation for a fleet for fighting purposes. So, although the line was established on paper as the fighting formation soon after the outbreak of the first Dutch war, it probably did not get firm hold until the third Dutch war. However, as a recognised order of battle it was embodied in the Duke of York's fighting instructions issued in 1665. These instructions were modified by Admirals Russell and Rooke at the end of the 17th and the very beginning of the 18th century, and Rule XIX. ran: 'If the admiral and his fleet have the wind (or weather-gauge) of the enemy, and they have stretched themselves in a line of battle, the van of the admiral's fleet is to steer with the van of the enemy's, and there to engage him, each ship from van to rear successively.' It was for acting contrary to this rule that Admiral Matthews was tried by court-martial and cashiered after his indecisive action with the French off Toulon on the 22d February 1744. His fault, for which he was condemned, was breaking (or quitting) his own line with the signal for the line of battle still flying; having formed his line, he broke it himself by running down to attack the French and Spanish centre. Admiral Lestock, the second in command, refused to obey. Both were tried, and Lestock was acquitted. These instructions were still in force in 1781, when Admiral Graves fought his action off the Chesapeake on the 5th September. And on the 5th July 1782 Sir Edward Hughes, in the East Indies, tried to engage the French fleet under Suffren according to Rule XIX. when he had the chance, but failed. According to Professor Laughton, they were not issued after that time. Admiral Rodney on the English side and Suffren on the French had shown that it might be better to leave a commander-in-chief free to act as the occasion required. These instructions also made no provision for engaging from the position to leeward. It would seem that the idea in Russell's and Rooke's minds was that the fleet to windward, whichever it was, was to engage. As a matter of fact, the French never engaged in that way, and as a rule utilised the position to windward to avoid action, as in Admiral Keppel's action in 1778, and in Rodney's two actions with Guichen in May 1780. The system of tactics put in practice by Sir George Rodney in his action with the French under the Comte de Grasse on the 12th April 1782 was by a curious coincidence used on the same day by the French admiral Suffren against the English squadron under Sir E. Hughes in the East Indies, the result of which was to free British admirals' hands, leaving it to their discretion how best to attack the enemy. This was simply concentrating the attack on a part of the enemy's fleet instead of dispersing it along the whole; there was nothing new in this or in the manœuvre by which it was effected, which was cutting through the enemy's line.

The honour of having been the first to demonstrate fully the principles on which the manœuvres of an attack against fleets to windward or to leeward depend is generally ascribed to John Clerk (q.v.) of Eldin, who published the first edition of his *Essay on Naval Tactics* in 1782, and it has been asserted that Clerk had in conversation communicated to Sir C. Douglas (Rodney's flag-captain) his whole system of tactics in the year before the action with the Comte de Grasse. This has, however, been disproved by Sir Howard Douglas in his *Memoir on Naval Evolutions*. As a matter of fact, it is well known that the manœuvre of cutting the enemy's line was several times performed by English commanders since the middle of the 17th century. In an action with the Dutch in 1652 Sir George Ayscue is said to have pierced the enemy's line from to leeward; and again in 1665 the Earl of Sandwich cut through the centre of the Dutch line and caused the disorder which ended in its total defeat. Again, in May 1672 Sir J. Jordan having the weather-gauge cut through the Dutch fleet and threw it into confusion. But it was unquestionably Rodney's important victory over the French in 1782 which gave the manœuvre such notoriety. From the account of the circumstances under which on this occasion the French line was broken, it appears that the idea of the manœuvre was at the moment suggested to the admiral by Sir Charles Douglas on perceiving an opening between two of the ships near its centre. The opportunity was seized of passing through: so narrow was the opening that the admiral's ship almost touched the French ships on each side; the ships astern followed him closely, and these kept up a powerful raking fire against the ships in the rear division of the enemy's fleet, which, being driven to leeward as the van of the British passed through, broke up and made sail before the wind to escape. At the battle of the Nile (1798) Nelson doubled on the van of the French line and attacked it on both sides, while the other ships of the line, the whole fleet being at anchor, could afford no assistance; but at Trafalgar, where his brilliant career terminated with a decisive victory, he broke the enemy's line in two places, bearing down upon it in two columns. Many persons even among naval officers have an idea that not only was Nelson no tactician,

but that he despised tactics altogether; the real truth being that he was certainly the greatest tactician of his day. Before each of his great actions he had thoroughly digested and arranged the best disposition of his forces, having carefully considered every possible position in which the enemy could be found, and he made a point of discussing the different situations with his captains, so that they were all acquainted with his plans and knew what was expected of them. Steam and armour-plating have since revolutionised the conditions under which naval battles must be fought; but with the one exception of the battle of Lissa in 1866, the only action in Europe in which ironclads have been pitted against each other, there has been no naval action which affords fresh data. The Italian fleet, consisting of eleven ironclads, four frigates, and some small vessels, was bombarding Lissa, when on the morning of the 20th July 1866 the Austrian fleet was reported approaching. Persano, the Italian admiral, formed his ironclads in line of battle, standing to the north-east, nearly at right angles to the course on which the Austrians were advancing. Albini, his second in command, receiving no orders, fell back on a sort of general understanding that wooden ships should not unnecessarily engage armoured ships, and, keeping well to the rear, practically took no part in the action. Tegethoff, the Austrian admiral, advanced at full speed; his seven ironclads were formed in a double quarter line (a double oblique line), his flagship, the *Ferdinand Max*, leading and forming the apex of the wedge. Following in the same formation, at a distance of about 1000 yards, came seven wooden ships, an old line-of-battle ship, the *Kaiser*, leading in the wake of the flagship; in rear of these again came seven gun-vessels. Tegethoff's plans had all been made and explained to his captains, and as he approached the enemy he made the signal, 'Ironclads to rush against and sink the enemy.' For some reason at the last moment Persano, whose flag had been flying on board the *Rè d'Italia*, determined to go on board the *Affondatore;* so he stopped for this purpose, and, as the van in the meantime held on their course, a gap was formed in the Italian line through which the Austrians passed, the Italian rear being at the same time attacked by the Austrian wooden ships. Their centre was exposed to the concentrated attack of the seven Austrian ironclads, so that, as the result of Persano's want of skill, with a fleet of twelve ironclads against seven, the actual condition of the fight was that three were opposed to the seven and annihilated by them, one, the *Rè d'Italia*, being rammed and sunk, while another, the *Palestro*, was blown up. Had Persano's subordinates been men of energy, in spite of the disaster to their centre the Italian van and rear would have destroyed the Austrian wooden division. As it was, with the exception of the *Kaiser*, the Austrian ships suffered but little.

It is impossible to forecast what the issue of the next great naval action will be, or what tactics will be employed. All battle-ships are armed with formidable rams, and in the opinion of many officers ramming will be one of the features of future battles; some ships may and probably will be rammed. But on the whole it is doubtful if ramming will be so generally resorted to, as there is always the possibility of the ship ramming being herself disabled by the shock; if she misses her aim, the ship attempting to ram will probably only succeed in putting herself into position for being rammed in turn; and if an enemy's ship is disabled, to sink her will not merely be to cause a wanton loss of life, but will also be to destroy what otherwise might be a valuable prize. It is, however, certain that the ships which can open an effective fire from their secondary batteries first will have an immense advantage; and whatever the formation for attack may be, to obtain the first fire will undoubtedly be one of the objects aimed at. For the rest, the formations of a modern fleet remain pretty much what they were at the beginning of the century. A fleet is organised in two or more divisions, and each division in two subdivisions. The principal formations are single column in line ahead (the old line of battle) and in line abreast, columns of divisions in line ahead and in line abreast, and quarter or bow columns. Some years back a new formation was tried, which for a time found great favour, but has now been given up; it was called the group system, and consisted of forming ships in groups of three; each group then became a tactical unit for manœuvring purposes.

H. Colomb, *Naval Warfare* (1891).

Tacuarembo, the largest department of Uruguay (q.v.), in the north centre, bounded S. by the Rio Negro, and devoted to stock-raising.

Tadcaster, a market-town in the West Riding of Yorkshire, occupying the site of the Roman *Calcaria*, on the Wharfe, 9 miles SW. of York. At Towton, 2½ miles S., on Palm Sunday, 29th May 1461, the Yorkists gained a great victory. Pop. 3000.

Tadema. See ALMA-TADEMA.

Tadmor. See PALMYRA.

Tadpole. See FROG.

Tael, a money of account in China, is equivalent to a tael weight of pure silver, or to about 1250 of the copper coin known as 'cash.' The value of the Haikwan tael or customs tael is about 4s. 9d. English, varying with the price of silver. In 1890 it was superseded by the new dollar, equal to that of the United States.

Tænia. See TAPEWORM.

Taffety, or TAFFETA (Persian *tâfta*), a term formerly applied to all plain silks simply woven by regular alternations of the warp and weft. Modifications have, however, been introduced, by varying the quality of the warp and weft, and by the substitution of various colours for the single one of the original taffety. It has therefore become a sort of generic term for *Plain Silk*, and even for some combinations of silk, wool, &c.

Tafilet. See MOROCCO.

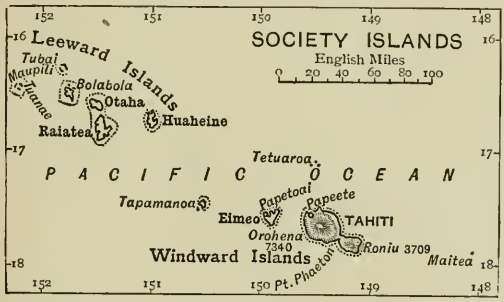
Taganrog, a seaport of Russia, in the government of Ekaterinoslav, on the north shore of the Sea of Azov, 15 miles W. of the mouth of the Don. The port is shallow, and the harbour unprotected; but there is a large export trade in wheat, as well as linseed, hempseed, skins, wool, butter, and tallow. The imports are mainly wine, machinery, and fruit. There are many handsome public buildings. Founded by Peter the Great in 1698, the town was bombarded during the Crimean war by an Anglo-French fleet. Pop. 56,047.

Taglioni, MARIA, a celebrated *danseuse*, born at Stockholm, 23d April 1804, of Italian parents, her father (Filippo Taglioni, born at Milan, 1777; died 1871) having been successively ballet-master at several opera-houses in different parts of the Continent. Mademoiselle Taglioni made her début in Paris in 1827, where she created a perfect furore, and was at once recognised as the first of ballet-dancers. Her success was equally great at Berlin, London, and other European capitals. She married Count de Voisins in 1832, and retired from the stage

with a fortune, afterwards lost. She died at Marseilles, 23d April 1884. Her brother Paul and her niece were also famous dancers.

Tagus (Span. *Tajo*), the largest river of the Spanish Peninsula, rises on the frontier of the provinces of Guadalajara and Teruel, on the western slopes of the Muela de San Juan. It first flows north-west, then curves to the south-west, and flows mainly in that direction past Aranjuez, Toledo, and Alcantara, and in Portugal, Abrantes, Santarem, and Lisbon, entering the Atlantic about 10 miles lower down. Below Salvaterra it divides into two arms, the western Tejo Novo and the eastern Mar de Pedro, which form a delta, the Lezirias do Tejo. Both fall into the noble Bay of Lisbon, which turns to the west and joins the sea by the Entrada do Tejo. It is navigable to Abrantes, from Santarem for steamers, even ocean-going vessels. Its total length is 566 miles; its drainage area includes 31,700 sq. m.

Tahiti, an island giving name to a small archipelago, also called Society Islands, in the middle of the Pacific, more than 2000 miles NE. of New Zealand and some 3400 SSW. of San Francisco. The islands consist of Tahiti, which embraces 450 sq. m. out of a total of 640 for the entire archipelago, and a number of smaller ones, the chief being Raiatea and Eimeo (q.v.). The group is divided into two clusters, called respectively the Windward



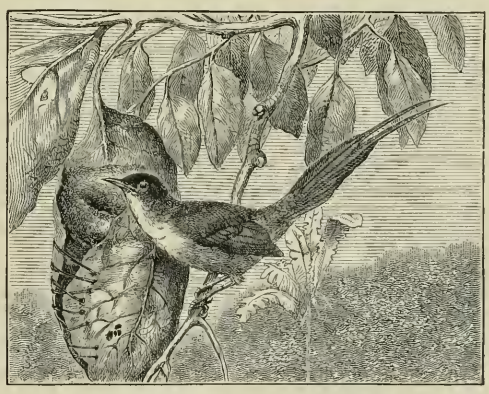
and the Leeward Islands, and stretches for about 200 miles in a north-west and south-east direction. They are composed of volcanic rocks, are mountainous (Orohena on Tahiti is 7340 feet high), and well wooded, with belts of low fertile soil along the shores. Coral-reefs encircle the separate islands, some of which are atolls, and numerous cascades foam down the mountain-sides. The scenery is magnificent, the chief island being often called 'the Garden of the Pacific.' The climate is very moist and hot (range 70° to 84° F.), but equable and healthy. Cocoa-nuts, oranges, vanilla, and all kinds of fruit are grown, as well as some cotton and sugar. Besides these things mother-of-pearl (the most valuable of all), cocoa-nut fibre, and trepang are exported. The imports (tissues, flour, wine, live-stock, sugar, coffee, coal, timber, soap) reached £116,958 in 1896, and the exports £130,795. The people cultivate for their own sustenance the bread-fruit, taro, yam, sweet potato, &c. There are several good harbours behind the shelter of the reefs; the most important is Papeete, the capital of the archipelago, which stands on the north-east of Tahiti, and has a Roman Catholic cathedral, an arsenal, and a population of 3500. The population of all the islands together, though more than half are wholly uninhabited, was 11,750 in 1895. The people, a handsome race of the Polynesian stock, are light-hearted, polite, and gay, but very immoral and untrustworthy; formerly, before they became so thoroughly Europeanised as they are now, they were notorious for their cruelty. The group was discovered by the Spanish navigator De Quiros, but first accurately described in detail by Cook (1769–77). He gave the name of Society Islands in honour of the Royal Society of London on the occasion of his first visit; at that time the population numbered nearly a quarter of a million. The London Missionary Society commenced work in these islands in 1797. But they have had unusual difficulties to contend against, and in 1812 they had to flee for a while to Australia. In 1842 the French forced a protectorate over the eastern (Windward) cluster, subsequently extended to the whole group, and in December 1897 a bill passed the French Chamber declaring them a French colony.

See Cook's *Voyages;* Desgraz, *Îles Taiti* (1844); Ellis, *Polynesian Researches* (1829); Williams, *Missionary Enterprise in the South Sea Islands* (1839); Pritchard, *Polynesian Reminiscences* (1866); and Dora Hort, *Tahiti: the Garden of the Pacific* (1891).

Tail, and **Tailzie.** See ENTAIL.

Taillandier, SAINT-RENÉ (properly René Gaspard Ernest), a French writer, born at Paris, 16th December 1817, studied at Paris and Heidelberg, and had already filled chairs at Strasburg and Montpellier, when he was called in 1863 to succeed Saint-Marc Girardin at the Sorbonne. He was admitted to the Academy in 1873, and died February 24, 1879. His chief work was to open up the art and literature of Germany to his countrymen in such books as *Histoire de la jeune Allemagne* (1849), *Études sur la Révolution en Allemagne* (1853), *Allemagne et Russie* (1856), and a translation of the Goethe-Schiller letters (1863). He contributed long to the *Revue des Deux Mondes,* and other of his works are *Scot Érigène et la Philosophie scholastique* (1843), *Histoire et Philosophie religieuse* (1860), *Écrivains et Poètes Modernes* (1861), *Drames et Romans de la Vie Littéraire* (1870), and *Études Littéraires* (1881), besides works on the Countess of Albany (1862), Marshal Saxe (1865), Philippe de Ségur (1875), and King Leopold and Queen Victoria (1878).

Tailor-bird (*Orthotomus sutorius* or *Sutoria sutoria*), a bird belonging to the family Sylviidæ. The male is about 6½ inches long; the general colour is olive-greenish; wings brown, edged with green; the two central tail feathers are long. It



Tailor-bird (*Orthotomus sutorius*).

is common in gardens, hedgerows, orchards, and low jungle in India, Burma, and China, being found usually in pairs, but sometimes in small flocks. The name tailor-bird is derived from the way in which the nest is formed. Two or three leaves are stitched together by means of silk from cocoons, thread, wool, or vegetable fibres, the necessary

holes being made by the bill. In the cup thus formed the nest is made, and consists of cotton-wool with a few horse hairs and some fine grass. The eggs are three or four in number, and are of two distinct types, the ground of the one being reddish white and of the other pale bluish green. The latter type is the rarer, and the two kinds of eggs are never found in the same nest.

Tain (Scand. *Thing*, 'a place of assembly'), an ancient royal burgh of Ross-shire, near the south shore of the Dornoch Firth, 44 miles NNE. of Inverness by the Highland Railway (1864). A ruined chapel marks the birthplace of St Duthac (*c.* 1000–65), whose body was brought back from Armagh in 1253; within it Bruce's queen was taken captive for Edward I., and James IV. did yearly penance here. There are also a collegiate church (1471; restored 1849–82), a court-house (1849), a public hall (1876), and an academy (1812). Pop. (1861) 2319; (1891) 2080, of whom 1632 were in the police and parliamentary burgh, Tain uniting with the four other Wick burghs to return one member. See the Rev. W. Taylor's *History of Tain* (1882).

Taine, Henri, French critic, so styled first through a whim of the editor of the *Revue des Deux Mondes*, his real name being Hippolyte Adolphe Taine, was born at Vouziers in Ardennes, 21st April 1828. He studied at Paris at the Collége de Bourbon and the École Normale, but his religious opinions barred the way to a scholastic career commensurate with his abilities. He filled minor parts at Toulon, Nevers, Poitiers, but soon threw up the state educational service to return to Paris, where after a short time of struggle he conquered fortune by the sheer strength and originality of his literary work. He took his *Doeteur ès Lettres* in 1853, writing for the occasion, besides the regular thesis, a treatise on Lafontaine's *Fables*—a masterpiece of critical analysis which established his reputation. Here at twenty-five he had reached the critical method which was to dominate him throughout life. His method is to make a searching investigation into the race, social conditions, and antecedents of the individual, his environment, the special tendencies of the age and their bearing upon him. These supply the key to the fundamental quality—the *faculté maîtresse*—of the author, which, once grasped, the critical judgment is complete and unassailable. But unfortunately *race*, *period of time*, and *environment* give completely different combinations to the reading of different observers, and with the help of all these it is only possible to see what one wishes or expects to see. The individuality is a subtle essence which eludes all this pretentious analysis, and these vast generalisations remain mere preconceived theories and foregone conclusions, the process the very opposite of the objective, the scientific, the certain. In 1854 Taine won the Academy's prize for an essay on Livy—an audacious application of the same critical method to a period of which he did not possess adequate knowledge. His *Voyage aux Eaux de Pyrénées* (1855) and *Voyage en Italie* (1866) are books that stand almost first of their class. In 1863 Taine was appointed to an examinership at St Cyr; in October 1864 he became professor of Æsthetics and the History of Art at the École des Beaux-Arts in Paris, thus finding a motive for his well-known subtle and paradoxical books on the Philosophy of Art, the Ideal in Art, and the Philosophy of Art in Italy, in Greece, and in the Netherlands. Already an Oxford D.C.L. (1871), was elected to Loménie's chair in the French Academy in 1878; he died 5th March 1893. Some of his maturest critical work is to be found in the *Essais de Critique et d'Histoire* (1857) and the *Nouveaux Essais* (1865); his most vigorous polemic in *Les Philosophes Français du XIX. Siècle* (1856), an attack on Cousin, Jouffroy, &c. The *Notes sur l'Angleterre* (1861) is perhaps his best book of its class, spite of its cleverness a warning example of the folly of splendid inductive theories without adequate knowledge. His famous *Histoire de la Littérature Anglaise* (5 vols. 1863–64; Eng. trans. by H. Van Laun, 4 vols. 1872–74) excited a clerical storm in France which cost him the Academy's prize of 4000 francs. The work is marred by sins of omission and commission alike, and by no means justifies its title—Sainte-Beuve suggested as an alternative, 'Histoire de la race et de la civilisation anglaises par la littérature.' But it remains the best work of the kind done by a foreigner, full of sympathetic insight and subtlety, and admirably written. Taine's greatest work, however, is his study of the Revolution, its causes and its issues, *Les Origines de la France Contemporaine* (*L'Ancien Régime*, 1875; the Revolution itself, in three sections, 1878–81–85; *Le Régime Moderne*, vol. i. 1890). As a psychological history of the greatest event in modern history this work stands absolutely alone. The first part is a patient and accurate study of the social state of France for a hundred years, proving the inevitableness of revolution and of its violence alike. Sheer love of truth has carried him through portentous labours in dusty archives, deeds, letters, and memoirs; and the results are set forth with unfailing exactitude and clearness, the only fault being that sometimes the reader feels that breadth of vision has been sacrificed to detail, and that he can scarcely see the wood for the trees. The treatment of the Revolution itself is original, courageous, and creditable in the highest degree to Taine when we consider his liberal antecedents and prepossessions. It constitutes the strongest attack yet made upon the men and the motives of the Revolution, the conclusion being much the same as that reached by Burke in his *Reflections*—to Taine 'a masterpiece and a prophecy,' although to Michelet a 'miserable piece of declamation.' He held before himself a lofty aim, and it must be said that this end he has attained—'J'ai tracé le portrait [of revolutionary France] sans me préoccuper de les débats présents; j'ai écrit comme si j'avais eu pour sujet les révolutions de Florence ou d'Athènes. Ceci est de l'histoire, rien de plus.'

See his *Derniers Essais de Critique et d'Histoire* (1895) and his *Carnets de Voyage* (1897); also Katscher in *Nineteenth Century* for July 1886; Bourget, *Psychologie Contemporaine* (1887); and the monograph by G. Monod, *Les Maîtres d'Histoire: Renan, Taine, Michelet* (1895).

T'âi-P'ings was the name given by foreigners to the followers of Hung Hsiû-ch'wan (S'eiw-tseuen), who raised the standard of rebellion in China in 1851, the enterprise not being finally suppressed till 1865. Hung was born in 1813 in a poor agricultural village of the district of Hwâ, in Canton province. His only chance of rising in the world being by literary distinction, he became a diligent student, but he never succeeded in taking the first degree at the provincial capital. Through his visits to Canton, however, he had obtained a bundle of Christian tracts, and gained, we must believe, some knowledge of foreign missions. Returning home from another disappointing competition in 1837, he fell into a long illness, in which he saw visions, and conceived the idea of changing the religion of the empire, and subverting the ruling Manchâu dynasty. When he got better he began to disseminate his new views, and could soon boast of two converts. These were like him-

self teachers of village schools, who by-and-by lost their pupils and came into angry collision with their neighbours. In 1844, in company with the elder of the two converts, Hung went into the adjacent province of Kwang-hsî, where they made many converts, and gathered them into communities which they called 'Churches of God.' Hung began also to give forth arrangements and decrees as revelations communicated to him by 'the Heavenly Father,' and the 'Heavenly Elder Brother.' The Heavenly Father was 'the Great God,' and the Elder Brother was 'our Lord Jesus Christ.' Meanwhile progress of organisation proceeded. A strictly moral conduct and the keeping of the Sabbath were enjoined on the congregations; all idolatrous practices and the use of opium were forbidden; proffers of union from leaders of the Great Triad Society, pledged to the restoration of a native Chinese dynasty, were rejected.

After some years of uncertain struggle with the official authorities, the insurgents (for such they were now) took possession of the district city of Yung-an. There they hailed their leader as emperor of the dynasty of T'âi-P'ing (Grand Peace), and adopted T'ien Kwo (Kingdom of Heaven) as the name of his reign. He was himself also styled T'ien Wang (Heavenly King), and some half a dozen of his oldest and most trusted followers were appointed by him his lieutenants, with the title of Wang (Kings). After being kept for some time in a state of siege in the city by their opponents, on the night of 7th April 1852 they burst forth, scattered their besiegers, and commenced their march to the north. Their number was only a few thousands, and they had no artillery, but full of enthusiasm they pressed on. We can only account for their success by recognising the unpreparedness and supine cowardice of the imperial officers and their troops. They passed from Kwang-hsî into Hû-nan, got command of the river Hsiang, and before the end of the year had reached the great Yang-tsze River. Launching forth on it, and taking on the way the capitals of Hû-pei and An-hûi, they encamped before Nanking on the 8th March 1853. Within ten days it had fallen into their power, and every man of the Manchâu garrison been put to the sword. Their host, grown in the twelve months from under 10,000 probably to more than 100,000, proclaimed the T'âi-P'ing dynasty anew, and swore fealty to the Heavenly King. In a few months a large force was despatched northwards to terminate the contest by the capture of Peking. This expedition did wonders, traversed the two provinces of An-hûi and Ho-nan, then marched west to Shan-shî, from which, turning east again, it penetrated into Chih-lî, and finally occupied an entrenched position only about 20 miles from T'ien-tsin. But the rebellion had there reached the limit of its advance. Though the expedition met with no great defeat, sufficient reinforcements did not reach them, and the leaders were obliged to retreat towards Nanking in 1855.

From this time the rebel cause began to decay. The moral enthusiasm which had distinguished it in Kwang-hsî disappeared. Dissensions arose between the kings, who strove and fought among themselves, and passed from the stage one after another. Hung created new kings to supply their places, but his name had ceased to be a word to conjure with. He secluded himself from public view, and was unable to institute any system of good order or administration in the extensive provinces subject to his control. The promise of Christian institutions died away. The imperial government, moreover, rallied its forces, and a desperate struggle ensued between them and the rebels. Some of the new kings proved to be men of great ability. Sû-châu and Nang-châu, the capitals of Chiang-sû and Chih-chiang, were both reduced and held by them for a time. How the struggle would have ended was still uncertain, when the imperialists began to call in the assistance of foreigners. A body of men of different nationalities entered their service under an American adventurer known to us from his taking this command as General Ward. He was a very capable man, and did the imperialists good service till he was killed in 1862. Then the British authorities at Shanghâi were prevailed on to organise a more effective force, and to put the whole auxiliary movement under the direction of Colonel Charles ('Chinese') Gordon (q.v.). The T'âi-P'ings fought with the courage of despair, but they could not long protract the final issue. Nanking was invested by the imperialists, and taken at last on the 19th July 1864. Hung himself, it is supposed, had taken poison a few weeks before, and so escaped capture. His son, a lad of sixteen years, fled under the protection of two of the kings, but they were all three soon taken and executed. What remnants there were of the fighting men made for the south in different bodies, but they gradually melted away, and were finally extinguished in Canton province in the following year.

Meadows, *The Chinese and their Rebellions* (Lond. 1856); *Pamphlets issued by the Chinese Insurgents at Nanking*, &c., compiled by W. H. Medhurst (Shanghâi, 1853); Andrew Wilson, *Gordon's Chinese Campaign and the Tai-Ping Rebellion* (1868); S. Wells Williams, *The Middle Kingdom* (revised edition, 1883); A. Egmont Hake, *Events of the Taeping Rebellion* (1892).

Tait, ARCHIBALD CAMPBELL, Archbishop of Canterbury, was born at Edinburgh, 22d December 1811, and was educated at the Edinburgh Academy and Glasgow University, whence he passed as a Snell exhibitioner to Balliol College, Oxford. In due time he became fellow and tutor, and was one of the four tutors who in 1841 protested against Newman's Tract 90. In 1842 he was appointed successor to Dr Arnold as head-master of Rugby, in 1849 became Dean of Carlisle (where he lost five little girls at once by scarlet fever), and in 1856 Bishop of London, as successor to Blomfield. Here he did much to bring the teaching of the church home to the people, instituting evening sermons in St Paul's, and encouraging open-air preaching; whilst the 'Bishop of London's Fund' for building schools, churches, and parsonages attained by his efforts to the amount of £350,000. A friend of compromise, though a foe to needless innovations, he showed much tact and personal kindliness in dealing with various controversies as to vestments and confession; condemned the Essays and Reviews, but promoted moderate measures; and though strongly hostile to Colenso's views, intervened to secure him fair-play. The same love of the *via media*, which caused him now to be accused of bigotry and now of indifference, he manifested when (having declined the Archbishopric of York in 1862) he was in 1868 made Primate of all England by Mr Disraeli. He assisted in composing the strifes raised by the question of Irish disestablishment, but was less successful with the Public Worship Regulation Act and the Burials Bill. He took a keen interest in missions, and greatly helped to extend and improve the organisation of the church in the colonies. The Lambeth Conference of 1878 took place under his auspices. He lost in 1878 both his only son, the Rev. Craufurd Tait, and his wife, a daughter of Archdeacon Spooner, whom he had married in 1843; and he himself died 3d December 1882.

See the Life by his son-in-law Bishop Davidson and the Rev. W. Benham (2 vols. 1891), and the Memoir of Catharine and Craufurd Tait by Benham (1879).

Tait, Peter Guthrie, natural philosopher and mathematician, was born at Dalkeith, April 28, 1831. He was educated at the Edinburgh Academy, and, after a year's study in Edinburgh University under Professors Kelland and Forbes, proceeded to St Peter's College, Cambridge. He was senior wrangler and first Smith's prizeman of 1852. In 1854 he was elected professor of Mathematics in Queen's College, Belfast, and in 1860 professor of Natural Philosophy in Edinburgh University. While in Belfast he assisted Dr Andrews in experimental researches into the nature of ozone. Subsequently he was associated with Balfour Stewart in experiments on the heating of a disc rotating in vacuo. His most important experimental work has been on thermo-electricity, on the pressure errors of the *Challenger* thermometers, on the effect of pressure on the maximum density point of water, on thermal conductivity, and on impact. To mathematical physics he has contributed several valuable memoirs, of which those on *Mirage* and on the *Kinetic Theory of Gases* and those involving quaternionic treatment call for special mention. These are all published in the *Transactions* of the Royal Society of Edinburgh, of which Tait has been general secretary since 1879. In pure mathematics his papers on *Knots* and on *Quaternions* are best known. He is recognised as the successor to Hamilton in the development of the calculus of Quaternions (q.v.), his *Elementary Treatise* (3d ed. 1890) being still the best working book for the student. The *Dynamics of a Particle*, by Tait and Steele, originally published in 1856 (6th ed. 1889), still holds its place as a text-book in Cambridge and elsewhere. In conjunction with Sir W. Thomson (q.v.; in 1891 made Lord Kelvin) Tait wrote the well-known *Treatise on Natural Philosophy* (vol. i. 1867; new ed. in two parts, 1879). *The Unseen Universe*, by Stewart and Tait (17th ed. 1890), and *Paradoxical Philosophy* (1878), a sequel to the former, have an interest for other besides scientific minds. Tait also took an important part in the preparation of the biographies of Principal Forbes, Professor Rankine, and Professor Andrews. Of his other writings we may mention *Lectures on some Recent Advances in Physical Science* (3d ed. 1885) and his text-books on *Light* (2d ed. 1889), *Heat* (2d ed. 1891), and *Properties of Matter* (2d ed. 1890); and two volumes of his *Scientific Papers* were published in 1898 and 1900. A tractate upon *Newton and the Laws of Motion* appeared in 1899. Various prizes and medals of the Royal Societies of Edinburgh and London have been awarded to him. His health failing, Professor Tait resigned his professorship in the spring of 1901.—His son, Lieutenant Fred G. Tait (1870–1900), the famous golfer, was shot in a reconnaissance near Koodoosberg in South Africa.

Tai-wan, once the capital of the island of Formosa (q.v.), still under its Japanese masters a large trading city, is on a plain about 3 miles from the south-west coast, with a pop. of above 60,000.

Takow. See Formosa.

Taku. See Peiho.

Talavera de la Reina, a picturesque but dirty old town of Spain, in the province of Toledo, beautifully situated on the Tagus, 75 miles SE. of Madrid by rail. It still manufactures pottery, and keeps up its famous fair in August. Here, on July 27–28, 1809, Sir Arthur Wellesley, with 19,000 men and 34,000 useless Spaniards, defeated 50,000 veteran French troops under Joseph Bonaparte and Marshals Jourdan and Victor. Pop. 10,497.

Talbot, a kind of dog deriving its name from the family of Talbot, who had a dog in their coat of arms. The talbot seems to have been the same as that also called the St Hubert's breed, the oldest of the slow-hounds and perhaps the original stock of the Bloodhound (q.v.).

Talbot, a historic English family, traces its descent from Richard de Talbot, named in *Domesday*, whose descendant, Richard, was made a baron (died 1306). The sixth baron, Sir John Talbot, Lord-lieutenant of Ireland, was the famous champion of English arms in France during Henry VI.'s reign, and is familiar to readers of Shakespeare. The hero of some forty victories, he was checked at Orleans by Joan of Arc, and routed and taken prisoner at Patay (1429). Created Earl of Shrewsbury (1442), he fell fighting against France in the eightieth year of his age (1453). The sixth and seventh earls are dealt with at Sheffield. The twelfth earl held prominent office under William III., Anne, and George I., as Lord-lieutenant of Ireland, and Lord High Treasurer and Lord Chamberlain of Great Britain. He was made Duke of Shrewsbury in 1694; but the dukedom died with him (1718). The senior male line of earls died out in 1856, and, after a disputed succession, the title passed to Henry John Chetwynd, third Earl Talbot, who became eighteenth Earl of Shrewsbury, and was the grandfather of the present earl. The Lords Talbot de Malahide are a distinct house, and represent a family settled in Ireland in the days of Henry II.

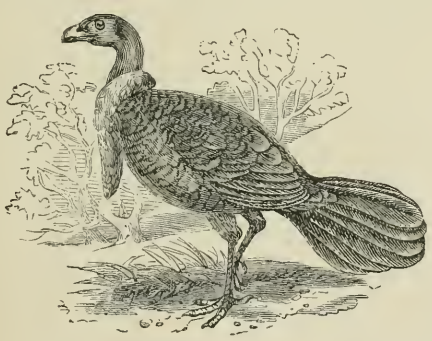
Talbot, William Henry Fox, celebrated in connection with photography, was born at Lacock Abbey, near Chippenham, on 11th February 1800. He passed from Harrow to Trinity College, Cambridge, where he graduated as twelfth wrangler and obtained the junior Chancellor's Medal in 1821. In the first reformed parliament Talbot sat for Chippenham; but scientific investigation being more to his taste, he gave up politics and devoted himself to the problem of fixing shadows. His principal services to photographic art, which in 1842 secured him a Royal Society medal, are described at Photography. Others lay in photoglyphic and 'photoglyphic' engraving. Latterly he devoted himself to the study of general physics and to philological and miscellaneous researches, and was one of the first decipherers of the cuneiform inscriptions from Nineveh. He died at Lacock Abbey, 17th September 1877. His *Pencil of Nature* (1846), one of the first works illustrated by photographs, describes his great invention. Amongst his works are *Hermes, or Classical and Antiquarian Researches* (1838–39); *Legendary Tales* (1830); *Antiquity of the Book of Genesis* (1839); and a work on *English Etymologies* (1846).

Talc, a mineral composed almost entirely of silica and magnesia, in the proportions of 63·5 silica and 31·7 magnesia, with 4·8 water. Its colours are silvery-white, greenish-white, and green. It has a pearly or semi-metallic lustre, and is unctuous to the touch, in which it differs from mica. It cleaves easily into thin flakes which are transparent and flexible, but not elastic. Its hardness = 1, hence it is readily scratched with the finger-nail. It usually occurs compact and not in good crystalline forms, but belongs either to the rhombic or the monoclinic system. It is also found massive, in beds associated with mica-schists, gneiss, and serpentine. Talc frequently occurs in rocks as an alteration-product, especially of magnesia minerals that contain little or no alumina.

Hence it frequently replaces enstatite, augite, hornblende, &c. It is found in Scotland, Tyrol, the Pyrenees, and various parts of the United States, and is or has been used like Mica (q.v.) for stoves and ovens, for slate-pencils, for surfaces exposed to acids, for stoppers of chemical bottles, &c.—A kind called *Indurated Talc*, or *Talc Slate*, has a curved slaty structure, and is not separable into laminæ like common talc. It approaches in character to steatite, and is used for similar purposes.

Tálchyr Beds, a group of strata occurring at the base of the Gondwána series of India. They probably occupy the same geological horizon as the Permian System of Europe, but owing to the rarity or absence of marine fossils their exact correlation with their European equivalents is somewhat uncertain. The beds are remarkable for the occurrence in them of numerous small and large erratics, some of the latter measuring 15 feet in diameter. In the neighbourhood of the Godavari the included blocks of foreign and transported rocks are smoothed, polished, and striated in the same manner as glaciated stones. Moreover, the hard Vindhyan limestone which underlies this Tálchyr boulder-bed is similarly smoothed and scored in long parallel lines.

Talegalla, or Brush Turkey (*Talegallus*), a genus of Gallinaceous birds, in the same family (Megapodidæ) as the mound-building Megapodes. Of the four species the Australian *Talegallus lathami* is best known. It is a large bird, almost the size of a female turkey, with blackish-brown plumage, pink-red head and neck, and yellow wattle. It inhabits the thickly-wooded parts of



Brush Turkey (*Talegallus lathami*).

New South Wales, and when pursued endeavours to escape by running through the thickest *brush*, or by leaping to the lowest branches of a tree, from which it ascends higher and higher, branch by branch. It thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting sleepily under shelter of the branches of trees. The Talegalla is generally seen in small flocks, and they make their nests together, the males heaping up, by means of their feet, mounds of several cartloads of earth and decayed leaves, which are used from year to year, new materials being added annually. The eggs are hatched by the heat of the sun and of the fermenting mound, each egg being separately buried. The parent birds partially uncover them during the day. It is said that nearly a bushel of eggs may sometimes be found in one heap. The flesh of the bird is excellent, and the eggs are also very delicate and eagerly sought after. It is thought that this bird might be added to the list of domestic poultry.

Talent (Gr. *talanton*, from a root 'to balance or weigh') was the heaviest unit of weight among the Greeks. The word is used by Homer to signify indifferently a balance and a definite weight of some monetary currency. Silver coin was first struck in Hellas proper in the island of Ægina, and the Æginetan standard was apparently adapted to the Babylonian gold standard. The Babylonian commercial talent seems to have been either 65 lb. 5 oz. or 66 lb. 5½ oz., and its value in silver from £340 to £400. Derivatives of this (containing 3000 shekels) were in use in Phœnicia and Palestine; but there was another silver talent, and a gold talent worth $\frac{4}{3}$ths of the commercial talent. The Euboic talent was of smaller monetary measure and weight than the Æginetan. Its use was mostly confined to Athens, Chalcis, and the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. About the middle of the 6th century B.C. the Attic standard arose, and it is impossible henceforth to distinguish the history of the Euboic from that of the Attic talent. These several talents were similarly subdivided into 60 minæ, the mina into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are Æginetan talent : Euboic talent : Attic talent :: 39 : 26 : 27, the weight and English money value of the first being 83¾ lb. avoir. and £303, 2s. 6d., of the second 55⅝ lb. and £203, 2s. 6d., and of the third 57$\frac{9}{7}$ lb. and £210, 18s. 9d. Besides the Attic talent there were other talents in use at Athens for weighing various articles. One of these was the Commercial or Emporic, which was identical with the Æginetan standard for coins and corresponded in use to our weight avoirdupois, being the ordinary weight in use in the market.

Talfourd, Sir Thomas Noon, was born at Doxey, near Stafford, 26th January 1795. The son of a Reading brewer, he was educated at the grammar-school there under Dr Valpy, and in 1821 was called to the bar at the Middle Temple. He became a serjeant-at-law (1833), Whig member for Reading (1835–41 and 1847–49), and a justice of Common Pleas (1849), at the same time being knighted. He died of apoplexy during Stafford assizes, 13th March 1854. Talfourd is remembered by his four nearly forgotten tragedies, of which *Ion* (1835) was brought out by Macready at Covent Garden; by his Copyright Act (q.v.) of 1842; and by his writings on Charles Lamb.

Taliacotius. See Rhinoplastic.

Ta-lien-wan, a port in Manchuria (q.v.), at the extremity of the Liáo-tung peninsula, was, with Port Arthur (q.v.), in 1898 leased by China to Russia nominally for twenty-five years.

Taliesin. See Wales (*Literature*).

Talisman (through Spanish from Arabic, but thence from the Gr. *telesma*, 'mystery,' 'initiation'), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms Talisman and Amulet (q.v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. A species of talisman which has acquired considerable celebrity is the Abraxas (q.v.). Another historic talisman is the Lee-penny, a heart-shaped, dark red jewel, now set in a shilling of Edward I., with a silver chain and ring attached, supposed to have been obtained in Spain by Sir Simon Lockhart, who set

out with Sir James Douglas to bear Bruce's heart to the Holy Land. So late as 1824 water in which it had been dipped was used to cure cattle bitten by a mad dog. A species of talisman at present in use in Asia is a piece of paper on which the names of the Seven Sleepers and their dog Kitmer are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons. Phylacteries (q.v.) were used as talismans; and in Christian Byzantium phylacteries were made bearing the figure of Solomon, the compeller of demons. See ASTROLOGY, DIVINATION, INCANTATION, MAGIC; and Pettigrew's *Medical Superstitions* (1844).

Tallage (from Fr. *tailler*, 'to share or cut out a part'), a name applied to those taxes to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject.

Tallahassee, the capital of Florida, 166 miles by rail W. of Jacksonville, has a state-house and cotton-factory; pop. (1890) 2933.

Tallegallus. See MOUND BIRDS.

Tallemant des Réaux, GÉDÉON, the Brantôme of his century, was born at La Rochelle about 1619. At nineteen he visited Italy in company with the future Cardinal de Retz, and at an early age married his cousin Elisabeth Rambouillet, daughter of a farmer of revenues, whose ample fortune enabled him to give himself to letters and to society. About 1650 he bought for 115,000 livres the seignorial estate of Plessis-Rideau in Touraine, and was permitted to change its name to that of Des Réaux. He was still living in 1691, but was certainly dead by 1701. His famous work, the *Historiettes*, was written from 1657 to 1659, and is invaluable as a complete picture of the society of his time. The most finished group of these portraits in miniature is that of the famous circle of the Hôtel de Rambouillet. There were many mortifications in that stately and ceremonious age to those sprung from the bourgeoisie, and these without doubt coloured the style and tone of Tallemant. He takes a malignant pleasure in setting forth the vices of the great, but, indeed, his mordant tone is a characteristic note throughout. He shows a relish for a scandalous story, and indeed often outrages the proprieties; but it should be remembered that he wrote only for his own diversion and that of a small group of intimate friends. His short characters, as printed by Monmerqué, are 376 in number, in no case finished biographies, rather collections of illustrative anecdotes, throwing strong light from behind the scenes on the leading figures of three-quarters of a century. And still more, those portraits may generally be accepted as sound and truthful, if some allowance is made for the natural maliciousness and personal prejudices of the writer.—His brother, the Abbé Tallemant (1620–93), was a man of wit and an academician, but his *Vies de Plutarque* (1663) brought him little credit.—His cousin, Paul Tallemant (1642–1712), early began to scribble verses, at eighteen wrote his *Voyage de l'Île d'Amour*, an ingenious commentary on Mdlle. de Scudéry's famous 'Carte de Tendre,' and entered the Academy in 1666.

The *Historiettes* of Tallemant des Réaux were first published, from the MSS. of the author, by MM. Monmerqué, the Marquis de Châteaugiron, and Jules Taschereau (6 vols. 1834). The second and more perfect edition was by Monmerqué alone (10 vols. in 5, 1840).

Talleyrand de Périgord, CHARLES MAURICE, Prince de Bénévent, the most inscrutable and resolutely self-regarding of modern politicians, was born at Paris on 2d February 1754. His father, Charles Daniel, Comte Talleyrand de Périgord (1734–88), was an officer in the army of Louis XV. during the Seven Years' War. An accident early in life, followed by an act of legal injustice, seems to have had a determining influence—for evil and not for good—on Talleyrand's character and career. By this accident he was lamed for life, and, in consequence, his rights of primogeniture were transferred to a younger brother, while he himself was, to his regret, educated not for the army but for the church. He threw himself, however, at the Collége D'Harcourt, at the Séminaire de St Sulpice, and at the Sorbonne, which he subsequently attended in succession, into the work of gratifying his ambition. He made himself a fair scholar, and cultivated the character of a rake and a cynical wit. His promotion, considering his well-known immorality, was rapid. He obtained the abbacy of St Denis in 1775, and five years later he was appointed *agent-général* to the French clergy; finally, Louis XVI. appointed him Bishop of Autun in 1789. Meanwhile he had been watching the signs of the times in France, and carefully studying politics. In 1789 the clergy of his diocese elected him to represent them in the States-general; and on this occasion he delivered a speech which at once stamped him as a political leader. He now became an authority on constitutional, financial, and educational questions, and the friend of men of such widely different gifts as Mirabeau, Sieyès, and Lally-Tollendal. He was one of the members of Assembly who were selected to draw up the Declaration of Right. He took a cynical delight in attacking the profession to which he still nominally belonged. It was he who in 1789 proposed the measure for the confiscation of the landed property of the church. He had rightly calculated that nothing could make him more popular with the rank and file of the revolutionaries in the Assembly; and on the 13th February was elected its president for the usual period. In November he took the oath to the new constitution, and in the beginning of 1791 he consecrated two new bishops—those of Aisne and Finisterre—declaring at the same time his sincere attachment to the holy see. It was now, however, open war between it and Talleyrand. In April he was excommunicated by the pope; he retaliated by giving up the clerical career altogether. About this time he was appointed director of the department of Paris in succession to Mirabeau. His most remarkable achievement, however, as a member of the National Assembly was his preparation of a report upon public instruction. This document was greatly in advance of the times, and was undoubtedly the model followed in all the great changes that subsequently took place, when France reorganised her educational system.

Talleyrand, although a favourite in Paris, had never been in sympathy with the fiercer spirits of the Revolution, and indeed was at heart a believer not in the Republic but in a constitutional monarchy. He was heartily glad, therefore, to leave France for London on an unofficial diplomatic mission early in 1792, and did his best to reconcile Pitt to his country, but failed. In December of the same year his connection with the Revolution was brought to a close by his being placed on the list of *émigrés*. He remained in exile in London till the end of January 1794, when he was compelled to leave under the provisions of the Alien Act. He had made many friends in London, and Lord Lansdowne having given him an introduction to Washington, he sailed for the United States. After the fall of Robespierre the sentence of proscription on him was recalled, and he returned to Paris in 1795. He attached himself to the party of Barras, and in 1797 he was called by the public opinion of the country to the post of foreign minister under the Directory.

Talleyrand was for a time the first man in

France, Barras being simply his tool. But he had already recognised the genius of Bonaparte, and established intimate relations with him. For a short period, however, he was in disgrace, the fact having been revealed that he had indicated his willingness to sell his services in connection with the conclusion of a treaty between Great Britain and the United States for money. But on the establishment of the Consulate he was restored to his former position as foreign minister, and for many years was closely associated with the fortunes of Napoleon. He had no genuine love for his master, but simply made him a means towards his own aggrandisement and enrichment. Gambling was his chief pleasure, and laid the foundation for an enormous fortune. Among the more odious of the acts of Napoleon with which Talleyrand will always be associated are the kidnapping and murder (March 1804) of the Duc d'Enghien. It is virtually beyond doubt that it was by his instructions that the crime was consummated in spite of the vehement opposition of Josephine, whose opposition led her to denounce him as a *maudit boiteux*. He was greatly instrumental in consolidating the power of Napoleon first (1802) as consul for life and then (1804) as emperor. When in the following year Great Britain, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of Talleyrand that it was partially broken up. To him as much as to Napoleon was owing the organisation in 1806 of the Confederation of the Rhine. Napoleon and he were thoroughly at one as regards the foreign policy of France till the conclusion of the peace of Tilsit in July 1807. After his creation as a prince of the empire under the title of Prince de Bénévent, he withdrew from the Ministry. The failure of Napoleon's designs in Spain was, however, the occasion of the first real rupture between him and Talleyrand.

Although Talleyrand was an advocate of the Austrian marriage, his voice was on the whole for a policy of wisdom during the later years of the first empire. In particular he was opposed to the invasion of Russia; and this gives some justification for his desertion of Napoleon in 1814. That desertion was complete and, from his own point of view, successful. He became the leader of the anti-Napoleonic faction; and through him communications were opened both with the allies and with the Bourbons. He dictated to the Senate the terms of Napoleon's deposition; and he became minister of foreign affairs under Louis XVIII., whom, indeed, he had placed on the throne. In his country's distress Talleyrand was now as much its good genius as was Thiers at a later and even darker period of its history. He negotiated the treaties by which the allies left France in possession of the boundaries which had been established in 1792, and in the congress which met in Vienna in September he successfully vindicated her rights to be heard in the readjustment of European arrangements. He had not calculated on the Hundred-Days, however, and offered no help to Louis, who, on Napoleon's escape from Elba, had retired to Ghent. Yet the allied powers insisted on his being taken back into royal favour, and after the second restoration he became prime-minister. He remained in office, though, only for a short time, as he found himself the reverse of a *persona grata* to the king, and disliked by all existing parties in France.

During the reigns of Louis XVIII. and Charles X. Talleyrand was little better than a discontented senator who never lost an opportunity of injuring the court and the government, although it is possible that his protest in 1823 against the Spanish war was animated by genuine regard for his country's interests. During the July revolution he was Louis-Philippe's chief adviser. The citizen king offered him the post of foreign minister, but he declined it. He went to London as ambassador, and was well received there. He reconciled the British ministry and court to France, and returned in triumph to Paris, and finally retired into private life in 1834, and died at Paris on 17th May 1838, at the age of eighty-four.

'A man living in falsehood and on falsehood; yet not what you can call a false man' is Carlyle's view of Talleyrand. 'That rather middling bishop but very eminent knave' is De Quincey's. Both views have been widely entertained; but Talleyrand is a puzzle—more of a puzzle since the publication of his *Memoirs* than he was even before. That he was shamelessly corrupt, immoral, selfish, and mendacious is beyond doubt. Nor was he a wise statesman in the modern sense; the amelioration of human society never entered into his calculations as an object to be aimed at. But he was amazingly clever, infinitely dexterous, and an admirable judge of men. It must also be said for Talleyrand that he separated himself from the latest and most disastrous ambitions of Napoleon, and that in his tortuous diplomacy he generally considered and sought his country's advantage as well as his own.

The Talleyrand *Memoirs*, published in 1891 under the editorship of the Duc de Broglie, and translated into English by Mrs A. Hall (5 vols. 1891–92), are disappointing and by no means reliable, but they must be consulted by any one who wishes to know how Talleyrand himself desired to stand with the world. For his public career the works of Mignet, Bastide, and Louis Blanc, the Lamartine, Guizot, and Rovigo *Memoirs*, Sir Henry Lytton Bulwer's *Historical Characters*, Sainte-Beuve's lectures, and above all Pullain's *Correspondence between Talleyrand and Louis XVIII.* (Eng. trans. 1881) should be consulted. Mere formal biographies, such as Michaud's *Histoire Politique et Privée* (1853) and Pichot's *Souvenirs Intimes sur M. de Talleyrand* (1870), are not to be trusted, as being little better than partisan pamphlets.

Tallien, JEAN LAMBERT, French Revolutionist, was born at Paris in 1769, and was first a lawyer's clerk, next employed in a printing-office, and made himself famous in the first months of 1791 by his Jacobin broad-sheet, *L'Ami des Citoyens*. He was conspicuous in the attack on the Tuileries (10th August), and became secretary to the Commune Insurrectionelle. He had his share in the infamous September massacres, and was elected by Seine-et-Oise to the Convention, where he was one of the most intemperate among the Jacobins, voted for the death of the king, was elected to the Committee of General Security, and played a part in the downfall of the Girondists (June 2). In September he went on his memorable mission to Bordeaux, where he extinguished all opposition under the guillotine, and disgraced himself by shameful profligacy. But a passion for one of his victims, the lovely Comtesse Thérèse de Fontenay (1775–1835), the daughter of the Spanish banker Cabarrus, changed his nature, and earned for her the title of 'our Lady of Pity.' He was recalled to Paris, yet on the 22d March 1794 was chosen president of the Convention. But Robespierre hated his insincerity and immorality, and Tallien, recognising his danger, rallied the trembling enemies of the Dictator with the energy of despair, and headed the successful attack upon him made on the 9th Thermidor. Tallien, now for a moment one of the most influential men in France, lent his aid to suppress the Revolutionary Tribunal and the Jacobin Club, and drew up the accusations against Carrier, Le Bon, and others of the Terrorists; but his importance ended with the Convention, and soon after the frail Thérèse, who had married him in December 1794 and reigned awhile the social queen of Paris, deserted

him for a wealthy banker. Bonaparte carried him to Egypt, and for some time he edited the official *Décade Égyptienne* at Cairo, but was dismissed by General Menou. On the voyage homeward he was captured by an English cruiser, and brought to England, where the Whig Opposition were stupid enough to make a hero of him (1801). Soon after he returned to France, and was through Fouché and by Talleyrand sent as consul to Alicante. He outlived the empire of Napoleon, and died in poverty, and almost hunger, at Paris, 16th November 1820.

Tallis, THOMAS, 'the father of English cathedral music,' lived in the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. The date of his birth is unknown, but it is believed to have been between 1510 and 1520. His first known appointment was that of organist of Waltham Abbey, which he held till the Abbey was dissolved in 1540, when it is conjectured he became a 'gentleman of the Chapel Royal.' In Day's Psalter, published in 1560, there appear eight tunes composed by Tallis, one of these being still used to Ken's evening hymn. In 1575–76 letters-patent were granted to Tallis and William Byrd (q.v.) according them 'the exclusive privilege of printing music and ruled music paper for twenty-one years.' The first work printed under this patent was issued in 1575, entitled, '*Cantiones quæ ab argumento Sacræ vocantur, quinque et sex partium,*' containing sixteen motets by Tallis and eighteen by Byrd. Tallis died on 23d November 1585, and was buried in the chancel of Greenwich parish church, with an epitaph in verse, which was afterwards set to music by Dr Cooke as a glee. Tallis, besides writing a large number of anthems, pieces, responses, and Te Deums (a complete list of which appears in Grove's *Dictionary of Music*), was the author of a celebrated work—'Song of the Forty Parts,' composed for eight choirs of five voices each. Tallis, it has been well said, was 'one of the greatest contrapuntists of the English school. His works are invested with great learning and much dignity, and are highly calculated to impress by their solemnity and power.'

Tallow. See FATS, OILS, LUBRICANTS, MINERAL TALLOW.

Tallow-tree, the name given to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. The tallow-tree of Malabar (*Vateria indica*) is a very large tree of the natural order Dipterocarpaceæ. The tallow-tree of China (*Sapium sebiferum* or *Stillingia sebifera*) belongs to the natural order Euphorbiaceæ, but has been naturalised in India, the West Indies, and in some parts of the southern United States. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. For the manufacture of candles the capsules and seeds are crushed and boiled, and the fat skimmed off whilst in a melted state. To improve the consistency, wax or linseed-oil is added to it. The name tallow-tree is sometimes given in North America to a species of Candleberry (q.v.).

Tally (Fr. *tailler*, 'to cut'), the name given to the notched sticks which, till the beginning of the 19th century, were used in England for keeping accounts in Exchequer, answering the double purpose of receipts and public records. They were well-seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and the one half was retained by the payer as his receipt, while the other was preserved in Exchequer. At the union of England and Scotland a store of hazel rods for tallies was sent to Edinburgh, but never made use of. An act of George III. (1783) decreed the discontinuance of tallies in Exchequer, but some use was made of them till 1812; the old tallies were ordered to be destroyed in 1834; and the overheating of the stove within the precincts of the House of Lords in which the tallies were burned caused the conflagration in which the old Houses of Parliament were destroyed.

Tally System is the name given to a mode of dealing by which dealers furnish certain articles on credit to their customers upon an agreement for the payment of the stipulated price by certain weekly or monthly instalments. This system of dealing is carried on chiefly in London and other large towns, in stores or shops known as tally-shops. Both seller and purchaser keep books in which the circumstances of the transaction and the payment of the several instalments are entered, and which serve as a tally and counter-tally. The prices charged under this system are usually exorbitant, and the goods sold, which principally consist of wearing apparel and cheap finery, furniture, hardware, and tea, are generally very inferior in quality. As a general rule, if a married woman in the absence of, and without the knowledge of, her husband, enters into a contract with a tallyman, her husband cannot, on his repudiating the contract, be made liable for the price of the goods unless they are strictly 'necessaries,' or unless he has directly or indirectly sanctioned the purchase.

Talma, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was born at Paris, 15th January 1763. He made a creditable début in 1787 at the Comédie Française as Séide in *Mahomet*, but the occasion of his first great success was his innovation in costume when playing Proculus in the tragedy of *Brutus*. Previously actors had worn the garb of their own country and even their own time. Talma appeared in a Roman toga. 'Look at Talma,' said a member of the company; 'how ridiculous he is! He has quite the air of an ancient statue!' a compliment as exquisite as it was unintentional. Henceforth Talma, aided by the counsels of the painter David, made a point of rigorous accuracy in costume; and his own remarkably handsome figure, fine voice, and perfect elocution, together with that matchless ease of movement which came after much labour, combined to fit him for the highest tragic rôles. But it was not till 4th November 1789, when he played Charles IX. in Chénier's play, that he rose to his full height in popular estimation. In 1791 he quarrelled with his associates, and with some other dissentients founded the Théâtre Français de la rue de Richelieu—the name changed next year to Théâtre de la République. Here he reigned throughout the Revolution in such characters as Othello; Nero in *Epicharis et Néron;* and Ægistheus in *Agamemnon*. Some of his later characters were among his best; Leicester in *Marie Stuart;* Sylla; Orestes; Leonidas; and Charles VI. Talma died 19th October 1826. See *Mémoires sur Talma*, by Moreau (1826), and his Autobiography, edited by A. Dumas (4 vols. 1849–50).

Talmage, THOMAS DE WITT, pulpit orator, was born at Bound Brook, New Jersey, 7th January 1832, and after holding several charges,

from 1869 to 1894 he was pastor of an important Presbyterian church in Brooklyn. His sermons were regularly published and translated into many tongues; and a long series of them have been issued in volumes bearing fantastic titles.

Talmud (from Heb. *lamad*, 'to learn;' i.e. '*The* Study') is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna and the Gemara, the former as the text, the latter as the commentary and complement. We have spoken under EXEGESIS of the gradual development of this 'Oral' or Post-mosaic Code, and at MISHNA have referred to the older collections upon which the Mishna was framed before being finally redacted in the form in which we now possess it. The oldest codification of Halachoth, or single ordinances, is due to the school of Hillel (q.v.). Simon, son of Gamaliel II. and great-grandson of Gamaliel I., mentioned in the New Testament, and his school carefully sifted the material thus brought together. He died 166 A.D. His son Jehudah Hannasî, commonly called Rabbi, who died 219, and his disciples brought the work to its close in six portions (Sedarim), 63 treatises (Mesichtoth), and 524 chapters (Perakim), which contain the single Mishnas. But besides this authoritatively compiled code there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, bylaws, and the like—partly portions of the ancient Midrash, partly either private text-books composed by the masters of the academies for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the dissensions which begot it, under the name of *Baraitoth*, 'foreign,' 'external,' by Chaiya and his school, in the succeeding generation. Not to be confounded with them, however, are the collections of *Tosefias*, 'supplements,' or *Great Mishnas*, which, commenced at the time of Jehudah Hannasî himself, and continued after his death by his scholar Chaiya and Hoshaiya, embody much of what has been purposely left out in the concise Mishna, which only embraced the final dicta and decisions. Such 'additions' we possess now to 52 treatises, forming together 383 Perakim or chapters. All these different sources of the 'Oral Law'—finally redacted before the end of the 3d century, though probably not committed to writing until 550 A.D.—belong to the period of from about 30 B.C. to about 250 A.D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification peremptory.

We must not omit to state here that this Mishna (Mathnisin), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna in all respects fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and moreover composed in as classical a Hebrew as still could be written in those days of decadence of the 'sacred language.'

The further development of this supplementary, oral, or second law—in fact rather an exegesis thereof—together with the discussions raised by apparent contradictions found in the individual enactments of the Mishnic doctors, is called Gemara—i.e. Discussion, Complement, or, according to another explanation, Doctrine. This Gemara contains, apart from the Halacha, which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, legends, and the like—called Haggada.

There are two Talmuds, the one called the Talmud of the Occidentals, or the 'Jerusalem' (Palestine) Talmud, which was closed at Tiberias, and the other the 'Babylonian' Talmud. The first of these now extends over thirty-nine treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. It originated in Tiberias in the school of Johanan, who died 279 A.D. Its final redaction probably belongs to the end of the 4th century; but the individual academies and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled 'our Talmud,' which was not completed until the end of the 5th century, and which makes use of the former. As the real editor of the Babylonian Talmud is to be considered Rabbi Ashe, president of the academy of Sora in Babylonia (375–427 A.D.). Both the Mishna and the Palestine Gemara had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academies. To put an end to these disputes and the general confusion arising out of them, which threatened to end in sheer chaos, Rabbi Ashe, aided by his disciple and friend Abina or Rabina I. (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Sora, in spring and in autumn. At the spring gathering he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and many years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is greatly due to Rab Abina II., head of the Sora academy (473–499). He was the last of the Amoraim expounders, who used merely oral tradition. After them came the Saboraim, the reflecting, examining, critical, the real completers of the Babylonian Talmud, and by many in ancient and modern times declared to have first reduced Mishna and Talmud to writing.

The Babylonian Talmud, as now extant, comprises the Gemara to almost the whole of the 2d, 3d, and 4th Sedarim (portions), further to the first treatise of the first, and to the first of the last

order. The rest, if it ever existed, seems now lost. The whole work is about four times as large as the Jerusalem one, and its thirty-six treatises, with the commentaries generally added to them in our editions (Rashi and Tosafoth), fill 2947 folio leaves. The language of the Talmud is, as we said, Aramaic (Western and Eastern), closely approaching to Syriac. The minor idiomatic differences between the two are easily accounted for by the different time and place; but the additional matter—quotations and fragments from older Midrash and Gemara collections, Haggada, &c.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (Tannaim) and of the Gemara (Amoraim) were followed by the Saboraim (see above). The code of the oral law had come to a close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die out as the popular language, and required a further study. The Saboraim no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularising the teachings laid down by their sires; apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th century, when Karaism (see JEWISH SECTS), which utterly denied the authority of the Talmud, sprang into existence. Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or to a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to a prosecution against the Jews in the Persian empire at the time of Yezdigerd II., Firuz, and Kobad (439–531), who closed the schools and academies for a space of nearly eighty years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance even when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q.v.) and the Tosafists of France and Germany. An abstract of the Talmud for practical legal purposes by Maimonides (q.v.) is called Mishne Thorah. The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice, by D. Bomberg, 1523. The Babylonian Talmud was first published at Venice by him in 1520. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. No translation of the Gemara has ever been carried further than a few single treatises. The complete Mishna, on the other hand, has been translated repeatedly into Latin, German, Spanish, &c. by Surenhus, Rabe, Jost, and others. We must refrain in this place from attempting a general characterisation of the Talmud, a work completely *sui generis*, which is assuredly one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the 'exoteric' history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been. In our own times, however, its value begins to be recognised by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at by eminent divines like Lightfoot and others.

See also JEWS, MISHNA, EXEGESIS, and an essay in the *Literary Remains* of Em. Deutsch, original author of the above article. Moïse Schwab has translated the Jerusalem Talmud into French (Paris, 1871; retranslated into English). The Babylonian Talmud has been translated or adapted by J. M. Rabbinowicz in his *Législation Criminelle du Talmud* (Paris, 1871), and *Législation Civile du Talmud* (5 vols. Paris, 1877); Aug. Wünsche, *Der Jer. Thalmud in seinen haggadischen Bestandtheilen ins Deutsch übers.* (Zurich, 1880), and *Der Bab. Thalmud in seinen haggadischen Bestandtheilen* (Leip. 1886); N. Brüll, *Die Entstehungsgeschichte d. Bab. Thalmud*, in *Jahrbücher f. Jüd. Gesch. u. Lit.* ii. (1876); Z. Frankel, *Introductio in Thalmud Hierosol.* (Breslau, 1870); W. Bacher, *Die Agada d. Palæstinensischen Amoräer* (Strasb. 1892); Jastrow, *Dictionary of the Targumim and the Talmud* (Lond. 1887–92).

Talpidæ. See MOLE.

Talus, a term employed in Geology to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

Tamaqua, a borough of Pennsylvania, on the Tamaqua or Little Schuylkill River, 134 miles by rail W. of New York. It has foundries and a shoe-factory. Pop. (1890) 6054.

Tamar, a river which through 45 of its 59 miles is the boundary between Devon and Cornwall; its estuary in Plymouth Sound is called the Hamoaze. See Mrs Bray's *Borders of the Tamar and the Tavy* (new ed. 1879).

Tamarind, a beautiful tree of the natural order Leguminosæ, sub-order Cæsalpineæ, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*Tamarindus indica*), a spreading tree, 30 or 40 feet high, with alternate pinnate leaves, which have from twelve to fifteen pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about 6 inches long. There are two varieties, the East Indian and the West Indian, the former having long pods containing from six to twelve seeds, the latter short pods with from one to four seeds. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp, in which the seeds are imbedded. West Indian tamarinds are usually imported preserved in syrup, the outer shell having been removed. The wood of the

Tamarind (*Tamarindus indica*), branch in flower: *a*, seed-pod section.

tamarind-tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme hardness, so that it is wrought with difficulty. The pods of some other trees of genera allied to Tamarindus are filled with a similar pulp, which is used in the same way, as the Tamarind Plum of India (*Dialium indicum*), and the Brown and Velvet Tamarinds of Sierra Leone (species of Codarium).

Tamarind pulp contains citric, tartaric, and malic acids, potash, sugar, vegetable jelly, &c. It is refrigerant and gently laxative, and, in combination with more active remedies, is often employed in the diseases of children. A kind of sherbet is also formed from it; and it is an excellent addition to curries. Cold tamarind tea, made by infusing tamarinds in boiling water, forms an agreeable and cooling drink.

Tamarisk (*Tamarix*), a genus of plants of the natural order Tamaricaceæ. This order contains rather more than forty known species, all natives of the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The Common Tamarisk (*T. gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalised in some places on the southern coasts of England. It sometimes attains a height of 30 feet. The twigs seem to possess tonic properties, and their medicinal virtues were once in high repute. The ashes of this and some other species of the genus contain much sulphate of soda. The Oriental Tamarisk (*T. orientalis*) is one of the few trees to be seen in the Arabian and African deserts, where its leafless appearance accords with the surrounding desolation. Galls are found on some species in India, and are valued both for medicinal use and for dyeing. *T. mannifera* yields a kind of Manna (q.v.). The German Tamarisk (*Myricaria germanica*), belonging to another genus of this order, is a smaller shrub than the common tamarisk, and abounds in many parts of Europe and Asia.

Common Tamarisk (*Tamarix gallica*): *a*, a flower.

Tamatave, a fortified port and important trading town of Madagascar, on the east coast, on a bay surrounded with reefs, with a good anchorage. Pop. 4000.

Tamaulipas, the northernmost of the Gulf states of Mexico (q.v.), with part of its low coast bordered by the southern Laguna del Madre. Capital, Victoria (pop. 7800).

Tamboff, the capital of a Russian government, 300 miles SE. of Moscow by rail. Pop. 36,000.

Tambookie-land, part of the Transkei (q.v.) territory.

Tambour (Fr. *tambour*, 'drum'), a frame upon which muslin or other material is stretched for embroidering. Tambour-work was extensively employed for the decoration of large surfaces of muslin, &c., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely that it has been largely superseded. See EMBROIDERY.

Tambourine, a very ancient instrument of the drum species, much used by the Biscayan and South Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it. It is composed of a piece of parchment stretched on the top of a hoop furnished with little bells, and is sounded by the hand, fingers, or elbow. When sharply struck by the hand the tambourine has not much effect, unless used in numbers. When sounded by gliding the fingers along the parchment a roll results, in which the bells are chiefly heard; and by rubbing the parchment without quitting it with the whole weight of the thumb the instrument gives out a wild, grotesque sound which is sometimes of service in masquerade scenes. The tambourine is nowadays much used by negro minstrels and Salvationists, and as a surface for young ladies' paintings.

Tamerlane, whose proper name was TIMUR or TIMUR-I-LENG (i.e. Lame Timur), one of the great conquerors who came forth from the heart of Asia during the middle ages, was born at Kesh (or Sebz), some 50 miles S. of Samarcand, in 1336, his father being the chief of a Mongol clan. Tamerlane's youth and early manhood had been full of adventure, when in 1369, having overcome all his rivals and enemies, he seated himself on the throne of Samarcand. The rest of his life, after he had organised the internal affairs of his kingdom, was spent in military campaigns, inspired by his lust of conquest. He subdued nearly all Persia, Georgia, and the other Caucasian states, and the empire of the Eastern Kipchaks or the Tartars (in 1390). But the military genius of Toktamish, chief of the Eastern Kipchaks and also of the Western Kipchaks or the Golden Horde, imposed upon Tamerlane a second long and determined campaign; but in the end (1395) he effectually humbled his former protégé and broke up his empire. India was the next object of his ambition. He conquered (1398) all the states between the Indus and the lower Ganges, and returned to Samarcand with a fabulous wealth of booty. He next set out to measure himself against the Turks in Asia Minor; but first turned aside to win Damascus and other strong places in Syria from the Mameluke sovereigns of Egypt. At length on the plains of Angora the Mongol and Turkish hosts came together; and, as the result of a gigantic battle, Sultan Bajazet was taken prisoner and his troops utterly routed. The victorious Tamerlane, after resting awhile at Samarcand, turned his eyes towards China, but died whilst on his way to that country, at Otrar, on the eastern side of the Syr-Daria, on 17th February 1405. Tamerlane seems to have been in many respects a typical oriental ruler of the abler class: in times of peace he mingled clemency with justice, and fostered learning and the arts, but in war he was cruel, implacable, and reckless of human life. He is the hero of Marlowe's *Tamburlaine.*

The recognised Life is Petis de la Croix's translation (1722) of one by the Persian writer, Sherif ed-Din. See also Sir Henry Howorth, *History of the Mongols* (1876–88), and Sir J. Malcolm, *History of Persia* (1828).

Tamil. See INDIA, Vol. VI. p. 103.

Tammany Society, a Democratic political organisation of New York City, derives its name

from an Indian chief who is said to have signed the treaty with Penn, and round whom many fanciful legends afterwards gathered. Washington's Pennsylvania troops chose him as their patron saint in place of St George; and on his 'day,' May 12, 1789, the society—although at first as the Columbian Order, to rival the Cincinnati (q.v.)—was founded under a grand sachem and twelve subordinate chiefs of tribes. The organisation soon became a party 'machine,' and by its aid Aaron Burr was raised to the vice-presidency. In 1805 the Tammany Society was formally chartered, its professed objects charity and the extension of the franchise. Its first hall was built in 1811; by 1822 the society had grown too large, and the management and practically all the power were transferred to a general committee of three delegates from each ward. Tammany took a leading part in city politics from the first, and flourished steadily; its new hall was built in 1867–68. Meanwhile the number of the general committee had risen to over 1400, delegates ultimately being sent from each district and precinct; and finally a central 'committee on organisation' was chosen from this unwieldy body, whose chairman was 'boss' of the hall. The most notorious of these 'bosses' was William M. Tweed, whose gigantic frauds, and those of the 'ring' of which he was the chief, were finally exposed in 1871; Tweed was convicted, and died in gaol while suits were pending against him for the recovery by the city of $6,000,000. This catastrophe crippled the power of Tammany, but its influence was by no means killed, though it is unquestionably used entirely for the pecuniary benefit of its leaders. In 1895 an investigation by the Lexow Committee showed extraordinary corruption in the police and municipal government, due to Tammany, which, notwithstanding, carried the municipal elections. In 1899 the State Legislature interfered and appointed another committee. The corruption discovered in the police and other departments was worse than ever.

Tammerfors, the chief manufacturing city of Finland, 50 miles NW. of Tavastehuus by rail. It is situated on a rapid which connects two lakes, and affords motive-power to cotton, linen, paper, and woollen mills. Pop. (1890) 20,483.

Tammuz. See ASTARTE.

Tampa, capital of Hillsborough county, Florida, at the head of Tampa Bay (nearly 40 miles long), 240 miles by rail SSW. of Jacksonville. It has a lumber trade and a good harbour; and Port Tampa, 9 miles SW. by rail, is the starting-point of steamers for Havana, Mobile, and other ports. Pop. 5532.

Tampico, a seaport of Mexico, in the state of Tamaulipas, on the Panuco, 9 miles from its mouth in the Gulf of Mexico, and about 200 (by rail, *viâ* San Luis Potosi, 637) miles NNE. of Mexico. Harbour-works were undertaken in 1889 to clear a channel, with the help of two jetties thrown out some 5000 feet, over the bar at the river-mouth, and permit ships drawing 24 feet to enter; at the entrance is an iron lighthouse 141 feet high. Situated on a small hill, with flat-roofed white houses and a fine cathedral, Tampico is much healthier than Vera Cruz, whose trade it threatens in time to draw away. Pop. 5000. See *Longman's Magazine*, July 1891.

Tamsui. See FORMOSA.

Tamworth, a town on the border of Stafford and Warwick shires, at the confluence of the Tame and Anker, 110 miles by rail NW. of London, 17½ NNE. of Birmingham, and 7 SE. of Lichfield. Burned by the Danes in 911, and rebuilt by the Princess Ethelfleda, it was the seat of a castle of the Saxon kings, which was afterwards held by the Marmion, Ferrars, and other families, and now belongs to the Marquis of Townshend. That castle, which ranges in date between Saxon and Jacobean times, crowns a knoll 130 feet high; in its noble round keep is a room where Mary Queen of Scots was a prisoner. The church of St Edith, restored since 1870 at a cost of £10,000, has some interesting monuments and a curious double tower-staircase. There are also a bronze statue of Peel (q.v.), the new Jubilee municipal buildings and assembly rooms, a town-hall (1701), a grammar-school (1588; rebuilt 1868), almshouses founded by Thomas Guy (q.v.), a cottage hospital, recreation grounds, &c. The manufactures include elastic, tape, smallwares, paper, &c.; and in the vicinity are market-gardens and coal-pits. A municipal borough, chartered by Elizabeth, Tamworth returned two members until 1885. Pop. (1851) 4059; (1881) 5778; (1891) 6614. See works by Palmer (1871–75).

Tan, FLOWERS OF. See MYXOMYCETES.

Tana, a river of British East Africa, running SSE. from Mount Kenia. See also THANA, TZANA.

Tanagers (*Tanagridæ*), a family of the Passeriformes, or perching birds, containing nearly 400 species; the bill is usually conical (sometimes depressed or attenuated), more or less triangular at the base, with the cutting edges not much inflected, and frequently notched near the tip of the upper mandible. This last character will generally serve to distinguish the tanagers from the finches, to which they are very closely allied; while on the other hand they have strong affinities to the American Warblers (Mniotiltidæ). They are mostly birds of small size, the largest barely exceeding a song-thrush, and the smallest, some of the genus Euphonia, being hardly 4 inches in length. This genus, with its ally Chlorophonia, is remarkable in having no gizzard; the birds belonging thereto feed chiefly on ripe fruits, which, with insects, form the principal food of the typical tanagers; some, however, feed on seeds and grain, like the finches. With the exception of a few species which visit North America in summer, the tanagers are confined to Central and South America and the West Indies. Some genera of tanagers are remarkable for their beauty of plumage, which is sometimes confined to the male sex, and sometimes possessed by the female also. Many are also pleasant songsters, such as the Organist Tanager (*Euphonia musica*) of San Domingo; the male of this species has the upper parts purplish-black, the cap blue, and the forehead, rump, and under parts yellow; the female being olive-green, with a blue cap, and lighter and yellowish below. The Scarlet Tanager (*Pyranga rubra*), visiting the eastern parts of North America in summer, and ranging south in winter to Ecuador, Peru, and Bolivia, is also a songster; it is larger than the preceding species, and the male is scarlet, with black wings and tail, while the female is olive, with the wings and tail brown. Tanagers do well in captivity, and several species may usually be seen in the Zoological Gardens.

Tanagra, an ancient city in the extreme east of Bœotia, on the Asopus, which suffered constantly in the wars between Athens and Thebes. Great finds of terra-cotta statues and statuettes have of late years been made in its necropolis.

Tanais. See DON.

Tananarivo. See ANTANANARIVO.

Tancred, one of the chiefs of the first crusade, was a son of the Palgrave Otho the Good and Emma, sister of Robert Guiscard, and was born in 1078. He joined his cousin, Bohemund of Tarentum, Guiscard's son, in the first crusade, and specially distinguished himself in the sieges of

Nicæa, Antioch, and Jerusalem. His reward was the principality of Tiberias. For some time he ruled his cousin's state of Antioch, and shortly before his death, on 21st April 1112, he was invested with the principality of Edessa. Tancred figures in the contemporary chroniclers as the beau-ideal of the crusading chivalry: before Tarsus he quarrelled with Baldwin, brother of Godfrey of Bouillon, but generously made up the quarrel when they came to the Holy City; after the storm of Jerusalem he endeavoured to save some hundreds of the captives from massacre; these and many other noble traits are recorded of him. He is the hero of Tasso's great epic.

Tandy, James Napper, Irish patriot, was born in Dublin in 1740, and became a prosperous and popular merchant there. One of the chief Protestant leaders of the popular interest, he took an active part in corporation polities, the free-trade agitation, and especially in volunteering affairs, and became the first secretary to the United Irishmen of Dublin. Early in 1792 he challenged the solicitor-general, Toler, for his abusive language, and was ordered to prison till the close of the session by the House of Commons for breach of privilege. As the viceroy had proclaimed him, with a reward for his apprehension, he had the temerity to raise a formal action for illegality against him and his privy-councillors, which was dismissed at the final hearing on November 26. For distributing in County Louth a 'seditious' pamphlet against the corruption of the powerful Beresford family he was about to be tried at the Dundalk assizes in the spring of 1793, when the government discovered the graver matter that he had met the Defenders at Castle Bellingham in County Louth, and taken their oath, with the view of effecting a coalition between them and the United Irishmen. Tandy fled to America, lived awhile at Wilmington in Delaware, and crossed to France in the spring of 1798, where Madden assures us he was raised to the rank of a general of division in the French army. He followed the ill-fated invasion of Ireland, and made a futile landing at Rutland Island, 16th September 1798, but returned on board that same night. He made his way to Norway, thence to Hamburg, the senate of which handed him over to the English government. On 12th February 1800 he was put on his trial at Dublin, but acquitted. But he was detained in custody, and again put on trial (7th April 1801) at Lifford, in County Donegal, for the treasonable landing on Rutland Island. This time he was convicted and sentenced to death, but, from the same motives of policy that engendered the peace of Amiens (27th March 1801), was permitted to make his way to France. He spent the rest of his days at Bordeaux, dying there in 1803. See Dr R. R. Madden's *United Irishmen* (3d series, vol. i. 1846).

Taney, Roger Brooke, American jurist, was born the son of a Maryland planter in 1777, admitted to the bar in 1799, and elected to the state senate in 1816. He was a courageous opponent of slavery as early as 1819. In 1824 he passed from the Federal into the Democratic party, and supported Andrew Jackson, who in 1831 appointed him attorney-general of the United States, and in 1833 secretary of the treasury. He encouraged and carried out the removal of the government deposits from the United States Bank (see Jackson), and in June 1834 the senate for the first time refused to confirm a president's nomination of one of his cabinet officers. But the balance of parties changed, and in 1836 the senate confirmed his appointment as chief-justice of the United States. His early decisions were strongly in favour of the doctrine of state sovereignty (see States' Rights), but his most famous decision was that in the Dred Scott Case (q.v.). He died 12th October 1864. There is a Memoir (autobiographical to 1801) by S. Tyler (1872).

Tanganyika, a lake of Eastern Central Africa, lying between 3° and 9° S. lat., long. of centre being 30° E.; length, 420 miles (nearly a fifth longer than Lake Michigan); breadth, from 15 to 80 miles; depth in some places very great. It was discovered by Speke and Burton in 1858. Livingstone and Stanley disproved in 1871 the theory till then accepted that the lake belonged to the Nile basin. Cameron surveyed the south and west coasts in 1874, and discovered an outlet, the Lukuga, on the west side. In 1876 Stanley satisfied himself that this channel, which he proved to communicate with the Lualaba or Upper Congo, is generally dried up in certain parts of its course, and only carries the overflow of Tanganyika westward at intervals of years. Thomson reaffirmed the connection between Tanganyika and the Congo by the Lukuga. Mr Hore found the height of the surface in March 1879 to be 2700 feet above sea-level; in August 1880 the water had fallen 10 feet 4 inches. Mr Hore believes that the lake had gradually for several years been rising to the former, apparently its highest level, that the obstructions in the Lukuga had then been carried away, and so the water had found its way to the Congo, making the Lukuga a permanent outlet. Except when several rainy seasons follow one another, the evaporation keeps the water about the same level; the evaporation is so great that the opposite shores, even if only 15 miles distant, are visible only in the rainy season. The water is fresh and wholesome, the climate not unhealthy. The lake is surrounded by high mountains, some of them attaining a height of 10,000 feet. The scenery is beautiful, and the shores abound in animals of all kinds. It is 600 miles from the coast; bounds the Congo Free State on the east, and on the west the German territory; has its south end in British East Africa; and as a link of connection between the Zambesi basin and the Nile is in a very true sense the heart of Africa. The 'Stevenson Road,' from Tanganyika to Nyassa (see Livingstonia), lies not far inside the British sphere. See Hore's *Tanganyika* (1892).

Tangent. See Trigonometry; and for Tangent-sailing, see Great Circle Sailing.

Tanghinin is a crystalline body extracted from the kernel of *Tanghinia venenifera* (natural order Apocynaceæ), which grows in Madagascar. It is a deadly poison, acting upon the heart like digitalis, strophanthus, and their allies, but possessing a convulsant action which these lack. Like digitalis it excites vomiting. Tanghin, an extract made by the Malagasy from the kernel, was used by them for the judicial Ordeal (q.v.).

Tangier, or Tangiers (Arab. *Tanja*), a seaport of Morocco, on a small bay or inlet of the Straits of Gibraltar, 38 miles SW. of the town of that name. It is a small, ill-built town, situated on two hills, the houses—with the exception of the residences of the foreign ministers to the court of Morocco, consuls, and officials—being, as a rule, miserable edifices, and the streets being narrow and dirty. The town is surrounded by old walls, and protected by several forts. It has an extensive shipping trade, though the harbour is a mere roadstead. Tangier was taken by the Portuguese in 1471, and given to Charles II. of England as dowry with Catharine of Braganza. It was held by England till 1683, when, on account of the expense and the badness of the climate, it was evacuated and the fortifications dismantled. The notorious Colonel Kirke (q.v.) commanded the

garrison, and Bishop Ken was for a short time chaplain. It was subsequently long a nest of pirates. Coal has been found here; and the place is visited by Europeans as a health-resort. Pop. 20,000, mostly Moors and Spanish Jews, with some 400 Europeans.

Tangle, a name given to various kinds of Seaweeds (q.v.), especially to Laminaria.

Tanis (Greek form of Egyptian *T'ân;* Heb. *Zoan*), an ancient Egyptian city in the north-east of the Delta, once the chief commercial city of Egypt, capital of the Hyksos kings about 2100 B.C., and of Rameses II. and other great monarchs of the 19th dynasty. Its prosperity was destroyed by the silting up of the Tanitic mouth of the Nile, which was named from it, and it was destroyed for rebellion in 174 A.D. The ruins near the fishing-village of Sân el Hager near the south shore of the Lake of Menzaleh were examined first by Mariette, and in 1883–84 explored by Flinders Petrie. See the explorer's monograph (1885).

Tanistry, an ancient Celtic mode of tenure, according to which the right of succession lay not with the individual, but with the family, in which it was hereditary; and by the family the holder of office or lands was elected, the design doubtless being that power should in this way be reserved for the strongest or worthiest of the stock—other things being equal, the nearest male relative of the actual tanist in possession. In the case of a monarchy it was the custom to appoint the heir-apparent during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne.

Tanjore (*Tanjúr* or *Tanjávúr*), a town of India, capital of a district in the Madras province, 180 miles SSW. of Madras city, in the midst of an extensive plain, on one of the branches of the lower Kaveri. The principal edifices of Tanjore are the great temple, described with an illustration at PAGODA, the palace of the old rajahs, and a dismantled fort. Silks, jewellery, carpets, copper vessels, and artistic models in clay, &c. are manufactured. Pop. (1881) 54,745; (1891) 54,060.

Tannahill, ROBERT, poet, was born at Paisley, the son of a hand-loom weaver, on 3d June 1774. From constant study of the poetry of Burns, Fergusson, and Ramsay the ambition was developed in him of emulating these favourite authors; and having been put to the loom after leaving school, he composed many of his best songs to the music of the shuttle. In 1800 he went with a brother to Lancashire, and remained there till 1802, when he returned to Paisley on hearing of his father's failing health. By the year 1805 his poems had become well known in the town, and a number of friends advised him to have them published. In 1807 he issued a volume of 175 pages entitled *Poems and Songs,* of which an edition of 900 copies was sold in a few weeks, to the profit of the author, who was able to deposit twenty pounds in the Union Bank. The poet was now famous, and heard his songs sung everywhere, special favourites being *Gloomy Winter's noo awa, Jessie the Flower o' Dunblane, The Braes o' Gleniffer, Loudon's Bonnie Woods and Braes,* and *The Wood o' Craigielea.* In 1810 the Ettrick Shepherd came to Paisley, and spent a night with Tannahill, who the following day convoyed Hogg half-way to Glasgow. It was a melancholy adieu Tannahill gave him. He grasped his hand, tears gathering in his eyes the while, and said: 'Farewell, we shall never meet again; farewell, I shall never see you more'—prophetic words soon to be verified. He had arranged a corrected edition of his works for the press, and offered them to Mr Constable, who returned the manuscript, as he had more new works on hand than he could undertake. This rebuff the poet was unable to bear, and he sank into despondency; two days before his death he threw into the fire all his new songs, nearly a hundred in number. On 17th May 1810 his body was found in a canal near Paisley; and there seems no reason to doubt that his death was that of the suicide. A granite obelisk marks his grave in the burying-ground of the West Relief (Canal Street) Church; and in 1883 a statue was erected in Paisley as a memorial of the poet. As a song-writer Tannahill continues to be remembered; and several of his pieces have established themselves as part of the musical repertory of the Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of Burns's force and passion he has little; but in grace and sweetness Burns himself has scarcely surpassed his happier passages. See Life in Semple's edition of his poems (1876), and Brown's *Paisley Poets* (vol. i. 1889).

Tanner, THOMAS, was born at the vicarage of Market Lavington, Wiltshire, January 25, 1674, and after graduating from Queen's College, Oxford, was in 1696 elected a Fellow of All Souls. He had already a high reputation as an antiquary, and Wood at his death in 1695 left him the care of his papers. He took orders, and became in succession chaplain to his father-in-law, Bishop Moore of Norwich, chancellor of Norwich, prebendary of Ely, rector of Thorpe near Norwich, archdeacon of Norwich (1710), canon of Christ Church, Oxford (1723), and Bishop of St Asaph (1732). He was thrice married, and died at Oxford, 14th December 1735. An improved and enlarged edition of his *Notitia Monastica* (1695) appeared in folio under the care of his brother in 1744. But Bishop Tanner's fame rests hardly less securely on his great posthumous biographical and bibliographical work—the labour of forty years, the *Bibliotheca Britannico-Hibernica* (ed. by Dr D. Wilkins, 1748). His edition of Wood's *Athenæ Oxonienses* he had published in 2 vols. folio in 1721.

Tannhäuser, the hero of one of the most beautiful of mediæval German legends, is a knight who, in the course of his travels, comes to the Venusberg, and enters the cave-palace to behold the wonders of the Lady Venus and her court. After having lived there some time in every kind of sensual delight, his conscience smites him, he invokes the Virgin Mary, and makes a pilgrimage to Rome, to Pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, when he hears his story, tells him that he can as little obtain God's mercy as the rod in his hand can become green again. Thereupon Tannhäuser departs in despair, and returns to the Lady Venus in the mountain. Three days after he had gone the dry rod begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain, for the knight can nowhere be found. Such is the story as told in the popular ballad once common all over Germany, and even beyond it. Elsewhere it is added that 'the faithful Eckhart,' of many German heroic legends, sits before the mountain, and warns the people of its dangers. In this shape the story may be traced as far back as the 14th century, but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Hoselberg or Hörselberg, near Eisenach, in which the Lady Hulda (see BERCHTA) held her court, who again suggests

Freyja the Scandinavian Venus. Grimm sees in the legend a touching portrayal of the regret that lingered in the popular heart for the dying paganism, and of the sternness of the Christian priesthood in regard to it. This idea of subterranean palaces in which the king or queen of dwarfs, pigmies, and fairies held their court seems to be universal. Everywhere stories are told of men, like Thomas of Ercildoune, being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. The visit of Ulysses to the isle of Calypso, and that of Circe are amplifications of the same idea. In later times the story has been treated by Tieck, and gave the subject for an opera to Wagner.

About the middle of the 13th century, and contemporary with Pope Urban IV. (1261–65), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, lived as a minnesinger at the court of the Austrian Duke Frederick II. the Quarrelsome, and after his death either with Duke Otto II. of Bavaria, or wandering from place to place. Tannhäuser composed fine spirited ballads.

For the legend, see Zander, *Die Tannhäusersage und der Minnesänger Tannhäuser* (1858); Grässe, *Der Tannhäuser und ewige Jude* (2d ed. 1861); also a slight paper in Baring-Gould's *Popular Myths of the Middle Ages*.

Tannin, Tannic Acid, or DIGALLIC ACID, is an astringent substance found in gall-nuts, and hence called gallotannic acid. The name tannin has, however, been applied to a number of different astringent compounds existing in the bark or leaves of most trees. These compounds, though not intimately related to each other, yet agree in giving blue or green-black compounds with salts of iron, and in producing leather by their action on animal skins. The true tannic acid is a colourless amorphous body, obtainable in fine scales or vitreous masses by the evaporation of its solution. A yellowish colour soon develops in the acid even when excluded from light. It is readily soluble in water and alcohol, but insoluble in chloroform. It reddens litmus, and has a powerful astringent taste and local action. On this account it is employed for relaxed throats as a gargle, or in the form of lozenge. As a styptic it is of much value. In the arts it is employed in the manufacture of ink, although most makers employ the crude gall-nuts in preference to the purified acid. The various tanning substances containing the other varieties of tannin are more employed in leather-making and Dyeing (q.v.).

Tanning. See LEATHER, BARK.

Tansa, a small river whose valley has been, at a point 65 miles N. of Bombay, impounded by the largest masonry dam in the world, for the water-supply of Bombay. The embankment, a little short of two miles long, is 118 feet high and 100 feet thick at the bottom, and contains over 11,000,000 cubic feet of masonry—all solid stone. The area of the dam is about 8 square miles, and the water-supply is equal to about 100,000,000 gallons per day. The works kept on an average from 9000 to 12,000 workpeople engaged for 5½ years; and the water was turned on by the viceroy, 31st March 1892.

Tansy (*Tanacetum*), a genus of plants of the natural order Compositæ, sub-order Corymbiferæ, allied to Artemisia (see WORMWOOD), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a slight membranous border. The species are pretty numerous, and are natives of the temperate parts of the Old World. Common Tansy (*T. vulgare*) is a native of Britain and of continental Europe, growing in fields and by roadsides, river-banks, &c. It has long been generally cultivated in gardens. It is now naturalised in many parts of North America. It is a perennial, from 2 to 4 feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter taste. The young leaves are used for flavouring puddings, cakes, omelets, &c. The plant is also tonic and anthelmintic, and *Tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *Tansy cakes* and *Tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the Paschal feast.

Tansy (*Tanacetum vulgare*).

Tanta, an important town and railway junction of Lower Egypt, between the Rosetta and Damietta branches of the Nile, with a famous mosque, a great fair, and a pop. of (1897) 57,289.

Tantallon Castle. See NORTH BERWICK.

Tantalum (sym. Ta, equiv. 182) is a very rare metal, discovered by Hatchett in 1801, and in 1802 by Ekeberg in the Swedish minerals known as tantalite and yttrotantalite. Wollaston regarded it as identical with Niobium (q.v.) or columbium, a view disproved by Rose in 1846. It is of no practical importance.

Tantalus was said to have been the son of Zeus, and some accounts describe him as king of Argos or Corinth. For having divulged the divine counsels of Zeus he was afflicted in the lower world with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them. Clusters of fruit hung over his head, which eluded his grasp whenever he endeavoured to reach them, his mind at the same time being kept in a state of constant terror lest a huge rock, suspended above his head, and ever threatening to fall, should crush him. Tantalus was the father of Pelops, Broteas, and Niobe.

Tantalus, or WOOD-IBIS, a genus of birds of the stork family (Ciconiidæ), quite distinct from the true ibises. The American Wood-ibis (*T. loculator*) is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is especially at home in South America, but also occurs in the southern states in swampy districts, and breeds abundantly in Florida. An allied African form, *Pseudotantalus rhodinopterus*, was for long regarded as the sacred ibis of the Egyptians, but this was a true ibis (*Ibis æthiopica*).

Tantia Topee, the most notable leader under Nana Sahib (q.v.) of the Indian Mutiny, who, in alliance with the Rani of Jhansi, held the field for a time after his chief had fled. He hid in the jungles of Central India till 7th April 1859, when he was captured and executed.

Tantra. See SANSKRIT, Vol. IX. pp. 153–154.

Tantum Ergo. See PANGE LINGUA.

Tâoism, the religious system founded by Lâo-tsze (q.v.). See also CHINA; Legge's *Texts of Tâoism* (1891); and De Rosny, *Le Tâoïsme* (1892).

Taormina, a town on the east coast of Sicily, on a lofty rock 900 feet above the sea, 35 miles SW. of Messina by rail. The ancient Tauromenium was founded about 358 B.C.; it has numerous relics of antiquity, as an aqueduct, tesselated pavements, and the remains of a theatre, reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence. Pop. 2388.

Tapajos, a navigable river of Brazil, and an affluent of the Amazon, is formed by the confluence of the Arinos and the Juruena, both of which rise in the south of Matto Grosso state. After a northward course of 900 miles, the Tapajos falls into the Amazon, above the town of Santarem. Steamers run 150 miles to the lowest of several waterfalls. A short portage separates the upper waters of the Tapajos from those of the Paraguay.

Tapestry is an ornamental textile used for the covering of walls and furniture, and for curtains and hangings. In its method of manufacture it is intimately related to oriental carpets, which are made in precisely the same way as certain kinds of tapestry, the only distinction being that carpets are meant for floor-coverings alone. Fine storied tapestries are, however, much more elaborate and costly than any carpets, and they have altogether different artistic pretensions. Tapestries are divided into two classes, according as they are made in high-warp (*haute lisse*) or low-warp (*basse lisse*) looms. The former in manufacture have their warp-threads stretched in a vertical manner with a roller at the top around which the warps are wound, and another at the bottom for receiving the finished tapestry. On the low-warp looms the warp is extended horizontally, there being an arrangement in both for shedding or separating the warp into two leaves, front and back, as in ordinary weaving. It is in high-warp looms that the most elaborate storied or pictorial tapestries are made, low-warp looms being more largely devoted to the production of still-life and non-pictorial decorative compositions. Notwithstanding these differences, it is difficult to distinguish between tapestries which have been made on high and low warp looms respectively, although the latter are more rapidly and consequently less expensively woven. In reproducing a design on the high-warp loom the workman has the portion of the cartoon he is copying behind him. He works from the back or wrong side of the tapestry, and to guide him the outline of the subject is slightly indicated on the warp threads. He has an endless number of shades and tones of wool and silk (formerly gold and silver threads were also used) which, with little shuttles, he shoots through the number of warp threads required for each particular shade, and with such wefts he covers and entirely encloses the warp-threads. In the reproduction of a design the utmost skill and experience are essential, not only to outline the figures and composition generally with accuracy, but also for the proper grading and hatching in of tones to secure the rich and mellow harmonies which constitute the principal charms of a picture. In low-warp tapestry-weaving the design to be copied is placed under the warp, and, as the workman here also weaves from the back, the design is reversed in the finished production. Of late years only it has become the habit to trace a reverse drawing on the warp-threads, whereby the tapestry is made to show the design as originally composed. The difficulty of examining low-warp work as it proceeds prevents the elaborate and delicate work being produced by this method which it is possible to secure on high-warp looms.

The art of tapestry-working is of high antiquity, and it may be that the curtains of the tabernacle 'of blue and purple and scarlet, with cherubim of cunning work' (Exod. xxvi. 1), were a kind of tapestry, though more probably they were of needlework. The so-called Bayeux Tapestry (q.v.) is really embroidered work of the period of William the Conqueror. The art of tapestry-working, and indeed all fine weaving, came to Europe from the East, and so well was this recognised that during the middle ages the fabric was generally known as *Sarruzinois*. So far as is known the art of high-warp tapestry-weaving was first practised in Flanders towards the end of the 12th century, and it flourished in the rich and prosperous towns of Arras, Valenciennes, Lille, Brussels, &c., and from the predominant importance of the first of these towns storied tapestries came to be generally known as 'Arras.' The disasters which overwhelmed the land during the contest with the Spanish power led many of the most skilful of the tapestry-weavers to seek an asylum in foreign lands, and thus the art spread to various European centres. Repeated attempts had been made in France from the middle of the 16th century onwards to establish the industry, but it was not till two Flemish workers, Comans and De la Planche, were engaged for an establishment formerly occupied by a family of wool-dyers called Gobelin (q.v.) that the industry was successfully founded and the famous Gobelins factory begun. From the early part of the 17th century to the present day the Gobelins has continued to be the source of the richest and most artistic of high-warp tapestries anywhere produced, and indeed that establishment may be regarded as the only source of fine storied tapestries of modern times. The manufactures of the Savonnerie, an establishment founded by Henri IV. for velvet-pile carpets and hangings, was in 1826 combined with the Gobelins, and the two industries are now carried on together by the state. There is also a state factory for low-warp tapestries at Beauvais; and at Aubusson and Felletin commercial tapestries are very largely made for furniture covering, &c., in establishments which in earlier times were celebrated for their tapestries *de luxe*. Tapestries were also made at an early period in England, and it is worthy of remark that English wool has always formed the staple for the finer qualities of the fabric. In 1619 an establishment was founded at Mortlake by Sir Francis Crane, and under his skilful guidance works of the very highest merit were produced. Throughout all the troubles of the Great Rebellion period Crane's factory continued in operation, and it was only in 1703 that it was closed. In 1872 some French tapestry-weavers were brought to Windsor, and a factory established there under royal patronage, which survived till 1888.

Tapestries — especially the high-warp storied varieties — are the textiles of kings. In earlier times the monarchs of Europe resorted to the Netherlands for pieces for the decoration of their palaces; and when the manufacture came to be more disseminated it was almost entirely under state supervision and control that the work was carried on. The pieces made were almost exclusively reserved for royal use, and to be given as presents in connection with great state celebrations and functions. The very foremost artists devoted their best energies to the production of designs and full-sized cartoons for the guidance of the weavers; and it was as patterns for tapestry that Raphael produced the immortal series of cartoons illustrating the acts of Christ and the Apostles

which were executed in Brussels for the Sistine Chapel. Seven of these cartoons, purchased by Charles I. under the advice of Rubens, are now in South Kensington Museum. It is worthy of remark that the earlier artists generally understood the conditions of tapestry design much better than the more recent painters who have supplied cartoons for copying. The cartoons of the early artists were simple in motive and decorative treatment, the masses were bold and broad, and the colour scheme harmonious without complexity. By modern artists the mistake was made of attempting, if not to rival, at least to copy oil-paintings with all their subtle harmonies and minuteness of detail. The mistake is now recognised, and among the regulations of the Gobelins is one that no tapestries will be there produced except from approved copies or cartoons made expressly for that purpose.

See A. de Champeaux, *Tapestry* (1878); Eugène Müntz, *Short History of Tapestry* (Eng. trans. by Sparkes, 1885); A. S. Cole, *Tapestry and Embroidery* (1888); the South Kensington *Descriptive Catalogue* (1888); French works by Guiffrey (1878), Havard (1889), and Gerspach (1892); works on special collections by Darcel, Loriquet, and Farabulini, and on ancient oriental tapestry by Riegl (Leip. 1890); also BAYEUX TAPESTRY.

Tapeworms, a term sometimes used as a popular synonym for Cestoda or Cestoid Worms (q.v.), but especially for those which belong to the families Tæniadæ and Bothriocephalidæ. In his diagnosis of the Tæniadæ Professor Leuckart notes the following points. The small pear-shaped or spherical 'head' bears, at some distance from the apex, four roundish suckers with powerful musculature. Between these there is usually, near the apex, a simple or manifold circle of claw-like hooks, which are supported and moved by a muscular rostellum. The 'joints' or proglottides are distinctly separated from one another, are usually longer than broad, are almost always provided with marginal generative apertures, and vary in number from three to three or four thousand. These joints are liberated from the host with great regularity, but somewhat late, after the embryos are well developed. 'The uterus has no direct communication with the exterior, so that the eggs remain inside the proglottides, and are only set free when these are destroyed.'

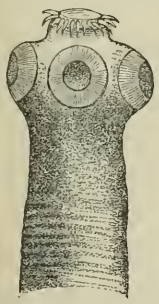


Fig. 1.—Head of *Tænia solium* (Leuckart).

The adult sexual Tæniadæ live for the most part in birds and mammals, the larval 'Bladder-worms' (q.v.) or Cysticerci occur in both higher and lower animals. In this family most zoologists recognise only one genus, Tænia, but there are so many species that Leuckart finds it convenient to recognise several sub-genera.

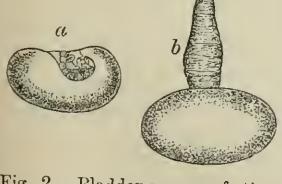

Fig. 2.—Bladder-worm of the Pig (*T. solium*):
a, with invaginated head, about natural size; *b*, with evaginated head, a little bigger than natural size (Leuckart).

In the Bothriocephalidæ the head is oval and flattened; the two suckers, devoid of special musculature, lie opposite one another longitudinally; the hooks, if present at all (Trianophorus), are without a rostellum; the 'joints' are indistinctly separate, always broader than long, and detached in numbers; the uterus has a ventral opening through which the embryos escape; these embryos are usually ciliated and able to swim about in water; the development is more direct than in Tæniadæ, for a true bladder-worm stage seems always wanting. The family includes a few genera—e.g. Archigetes, Ligula, Triænophorus, but the most important practically is Bothriocephalus.

Two Tæniadæ are in their adult sexual state parasitic in man: *Tænia solium*, with the bladder-worm stage in the pig; *T. saginata* or *mediocanellata*, with bladder-worm in the ox; and some others, *T. cucumerina*, *T. nana*, *T. flavomaculata*, and *T. madagascariensis*, occasionally occur. They infest the small intestine, and there also *Bothriocephalus latus* (larval in pike and burbot) may be found. Moreover Tænioid bladder-worms also occur in man, the most important being that of *Tænia echinococcus*, which lives as an adult tapeworm in the dog.

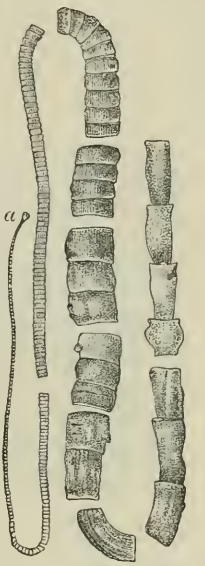

Fig. 3.—Portions of *Tænia mediocanellata*, about half natural size (Leuckart).

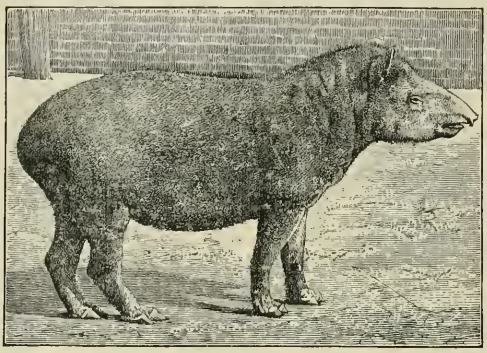
In the majority of cases man becomes infected with tapeworms through eating the raw or imperfectly cooked flesh of the animal—be it ox or pig or fish—which is the host of the immature stage of the parasite. In other cases filthy habits of living and eating render it readily possible for the bladder-worms—or, in the case of *T. echinococcus*, the ova—to get mixed up with the food. The presence of tapeworm in the small intestine need not be dangerous—indeed, the Abyssinians regard freedom from the parasite as a disaster; but it is usually troublesome, giving rise to disturbances of digestion, colic-like pains, diarrhœa, or, on the contrary, constipation, besides less local effects, such as anæmic and neurotic states. No certain diagnosis is possible, 'unless the eggs or proglottides of the *corpus delicti* be observed, and these must always be identified before so radical a cure as treatment with anthelmintics is begun.' Of these anthelmintics—which are intended to expel the parasite from the intestine—there is no lack in the pharmacopœia. But, as Leuckart insists with evident reasonableness, prevention is better than cure.

See Leuckart, *The Parasites of Man*, trans. by Hoyle (1886); and, for tapeworm in dogs, WORMS.

Tapioca, a farinaceous substance obtained from cassava or manioc (when prepared as explained at MANIOC) by drying it while moist on hot plates, so that the starch grains swell or burst, and the whole agglomerates in small lumps. The name is sometimes given to a kind of Sago (q.v.).

Tapir (*Tapirus*), a genus of Ungulata, of the section Perissodactyla, having a bulky form, with moderately long legs; the fore-feet four-toed, the hind-feet three-toed; the skin thick, the hair short; the tail very small; the neck thick; the ears short; the eyes small; the muzzle elongated; the nose prolonged into a short, flexible proboscis, which, however, does not terminate in an organ of touch and prehension, like that of the elephant; six incisors, two canine teeth, and fourteen molars in each jaw, the molars separated from the canine

teeth by a wide interval. There are certainly four species, of which three are American and one Oriental. The best known is the American Tapir (*T. terrestris*), which is about the size of a small ass, and is common in almost all parts of South America, its range extending as far south as the Strait of Magellan, although it suddenly ceases to be found at the Isthmus of Panamá. Its colour is a uniform deep brown, but the young are—as in many other animals (e.g. the Puma) which when adult are of all one colour—marked with yellowish fawn-coloured stripes and spots. The skin of the neck forms a thick rounded crest on the nape, with a short mane of stiff hair. The tapir inhabits deep recesses of the forest, and delights in plunging and swimming in water. It feeds chiefly on young shoots of trees, fruits, and other vegetable substances,



American Tapir (*Tapirus terrestris*).

but is ready to swallow almost anything that comes in its way. Pieces of wood, clay, and pebbles are often found in its stomach. It sometimes commits great ravages in cultivated grounds; a large herd of tapirs sallying forth from the forest by night, trampling and devouring all that they find in the fields. The tapir is a very powerful animal, and, protected by its thick hide, forces its way through the forest where almost no other quadruped can. When assailed by the jaguar it seeks to get rid of him by rushing through thick underwood, and if it can reach water is often successful by plunging in and diving. It is inoffensive, never attacking man, but when hard pressed by dogs makes a violent resistance, and inflicts severe bites. It is very easily tamed, and becomes extremely familiar; but its large size makes it a troublesome pet. Its hide is useful, and its flesh is eaten, although rather dry. The other two American species—viz. *T. bairdi* and *T. dowi*—are generally regarded as generically distinct from the rest, and have been termed *Elasmognathus*. The Malayan Tapir (*T. indicus*) is found in Malacca, Sumatra, &c. It is larger than the American tapir, and its proboscis is rather longer in proportion. The neck has no mane. The colour is glossy black, except the back, rump, and sides of the belly, which are white. The colours do not pass gradually one into another, but the line of separation is marked, giving the animal a very peculiar appearance. The habits of this species are very similar to those of the American tapir, and it is equally capable of domestication. The young are striped and spotted as in that species.

The remains of tapirs have been found in Miocene and subsequent strata. In all about twelve species have been determined. Tapir-like animals are common in Eocene beds. *Lophiodon* appears to have been the precursor of the tapirs during the Eocene period. True tapirs are found in beds of an earlier age (Miocene) in Europe than in America (Post-Pliocene). Hence it has been argued that the tapir is an Old-World form which migrated to the New World, and ultimately established itself there upon a firmer footing.

Tapping is an operation frequently resorted to for the removal of fluid accumulations, particularly in the pleural and peritoneal cavities. It consists in introducing one end of a small tube into the cavity, with the least possible injury to the skin, and withdrawing so much of the fluid as is desired by siphon action, or by means of a vacuum. Various contrivances (aspirators) have been used to effect this without allowing air to enter—the commonest form that devised by Dr Potain. These instruments have done much for the certain diagnosis and safe treatment of fluid collections in various situations. Besides dropsical or inflammatory exudations in the pleura or peritoneum, similar collections in the pericardium can be thus dealt with; cysts and abscesses, when deep-seated and obscure, can be recognised with certainty and sometimes cured; and occasionally the fluid present in chronic hydrocephalus can be diminished with amelioration of symptoms. Collections of air or gas within the body may sometimes be removed in the same way with good results. See Dropsy, Pleurisy, &c.

Taprobane. See Ceylon.

Tapti, a river of Bombay, rises in the Betúl district of the Central Provinces, and flows 450 miles west through the Sátpura uplands and the districts of Candeish and Surat to the Gulf of Cambay, 17 miles below the town of Surat. Even small vessels of 40 to 50 tons burden cannot ascend higher than Surat. The port of Suwali, at the month, is now deserted, and the lower channels of the river are being silted up.

Tar. The nature of tar differs according to the raw material from which it is derived. In nearly all cases it is a thick, black, or dark-brown liquid of complex composition. The tars of commerce have a strong characteristic odour varying with their origin. When wood, coal, or shale is subjected to destructive distillation in close vessels there are produced (1) incondensable gases, (2) a liquid portion consisting of various substances soluble in water, and (3) another portion composed of bodies insoluble in water. This third or last portion is generally called tar. In former days wood-tar was used for much the same purposes as that for which the residual pitch derived from it is employed now. The time has come when any kind of tar is looked upon rather as a mother-liquor from which valuable chemical substances are obtained than as a material to be used by itself in the arts.

Wood-tar.—Different woods yield tars of a so far unlike nature. The tar from pine-wood is not the same as that from oak or beech. Most of the wood-tar produced in Europe is obtained from the Scotch fir (*Pinus sylvestris*), but it is also got from other pines and from larch. Coniferous wood yields from 14 to 18 per cent. of tar, while from the wood of dicotyledonous trees of temperate regions only from 9 to 10 per cent. is obtained. Wood-tar is still made by the very old process of burning wood in cone-shaped piles covered over with sufficient earth and turf to exclude air, of which just enough is admitted to promote combustion by means of apertures at the bottom where the pile is ignited. The pile stands on a clay floor, and it is fully a week before any tar is collected. By this rude process much charcoal, crude acetic acid, and other products are wasted; but these are now very often saved by distilling the wood in close vessels. Several forms of retorts or kilns are

employed to make charcoal and at the same time to yield tar. One kind of kiln is in the shape of an oblong brick chamber, arched over, and with a floor formed into a sort of channel sloping from the middle of the chamber, where it is highest, to each of the end walls. Its internal size is 25 feet long, 12 feet wide, and 15 feet to top of arch. The chamber is closely filled with wood, the only place where a small space is left being where the flame or heat from the fire enters at one side. Air must be as far as possible excluded during the charring of the wood, which in a kiln of this kind may consist of stumps, branches, and any sort of odd pieces. The fire hearth, placed just outside the side wall of the chamber, has no grate, so as to prevent too much draught. As the tar is formed it runs down the right and left inclines of the channel, and at each end, by one branch of a two-way pipe, is led into a tar vessel, while the more volatile acetic acid and wood-spirit pass by the upper branch of the pipe into a condenser. Wood-tar contains (besides the tar proper) a large admixture of watery distillate, and gives on redistillation acetic (pyroligneous) acid, wood-spirit or methyl-alcohol, methyl-acetate, acetone, wood-creasote, and wood-naphtha, consisting of hydrocarbons very often containing methyl groups replacing hydrogen; also heavy oils and crystalline bodies not yet much investigated and that disappear in the pitch. Tar from some resinous woods contains oils resembling turpentine in composition. Before American petroleum became so cheap an oil of this kind was made in Norway and burned in paraffin-lamps.

In medicine tar and tar-ointment are used for cutaneous diseases (such as psoriasis), and much controversy arose as to the virtues of tar-water, regarded by Bishop Berkeley as almost a panacea. Tar-water was the watery liquor obtained when a quart of wood-tar and a quart of water had been well shaken together and allowed to settle. This Berkeley found was used, taken internally, as a preventive and palliative of smallpox in the American colonies. He tried it and found it exceedingly useful, he says, for consumption, fevers, ulcers, pleurisy, gravel, stomachic disorders, &c.; and on it bases his *Siris or Treatise concerning the Virtues of Tar-water*, a chain of philosophical reflections, which, as Professor Fraser says, connects tar-water with the throne of the Divine Ruler of the universe.

The use of tar or pitch for 'tarring and feathering' obnoxious persons, still understood to be practised in some parts of the United States in execution of mob-law, is of very ancient origin, dating apparently at least from the times of the Crusades. According to Rymer's *Foedera* and Hakluyt's *Voyages*, King Richard I. enacted for the royal navy that a thief or felon 'lawfully conuicted, shal haue his head shorne and boyling pitch powred vpon his head, and feathers or downe strawed upon the same, wherby he may be knowen.' Scarron (q.v.) was reported to have tarred and feathered his own person as a carnival disguise.

Coal-tar or Gas-tar.—In the making of gas for illumination the coal is distilled at a higher temperature than that used for the production of ordinary coke, the result being that the constituents of the tar from the two processes differ. Gas-tar contains more benzole and other colour-making materials than coke-tar. See COAL-TAR.

Coke-oven Tar.—Until recently the recovery of the volatile products, such as tar and ammonia, given off during the conversion of coal into coke was neglected. Coke-ovens are, however, now constructed which, among other improvements, include the collection of the tar, the nature of which depends upon the temperature at which the coal is distilled. In the Jameson coke-oven the temperature is low at the point of destructive distillation, and consequently the tar produced contains paraffin and the higher phenols. On the other hand, the Simon-Carvés coke-oven, in which a high temperature is reached, produces a tar more resembling that obtained in coal-gas making. It is characterised by the presence of naphthaline and Anthracene (q.v.), and small quantities of benzole and carbolic acid.

Blast-furnace Tar.—In some cases the tar from iron blast-furnaces in which coal is used as fuel is now recovered. It is of an intermediate quality between the two kinds of coke-tar just noticed, but rather more resembling that produced at a high temperature.

Lignite or Brown Coal and Peat were distilled some years ago to yield tars. The former gave a considerable yield of buttery tar containing about 15 per cent. of paraffin. From the latter a tar was obtained, also yielding some paraffin.

Tara. See TARO.

Tara, HILL OF, an eminence (507 feet) in County Meath, 7 miles SSE. of Navan. Here prior to 560 is said to have stood the hall of the kings of Ireland; and here O'Connell (q.v.) held a monster meeting on 15th August 1843.

Tara Fern (*Pteris aquilina*), a large species of Bracken (q.v.), the rhizome of which was one of the principal articles of food of the Maoris before the settlement of New Zealand by British colonists. The roots, about an inch in circumference, were cut in pieces, dried, and stacked. For use the root was steeped in water, dried in the sun, and then roasted. Good flour was obtained from it by beating on a stone.

Taranaki (formerly New Plymouth), a provincial district of New Zealand, occupying the south-west corner of the North Island; area, 2,137,000 acres, of which three-fourths is dense forest. The coast is lined with iron-sand. The soil and climate are good for rearing stock, and being well watered grass and root-crops are abundant. Pop. (1891) 22,169. Capital, New Plymouth; pop. 4000. See B. Wells's *History of Taranaki* (New Plym. 1878).

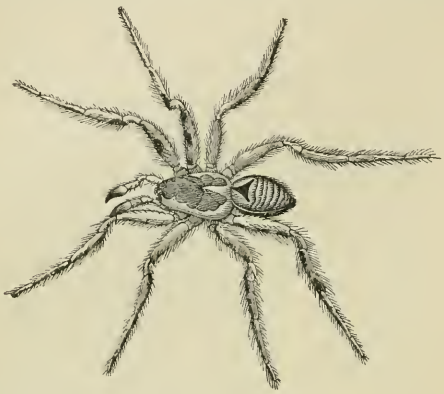
Taranto (anc. *Tarentum*), a seaport of Southern Italy, in the province of Lecce, situated on a rocky islet between the Mare Grande or Gulf of Taranto and the Mare Piccolo, an extensive natural harbour on the east side of the town, 72 miles SSE. of Bari by rail. The harbour is sheltered by two small islands, San Paolo and San Pietro, the *Chœrades* of antiquity, and is closed by Cape San Vito on the south-east. The town is joined to the mainland by a six-arched bridge on the east side, and on the west by an ancient Byzantine aqueduct. The principal buildings are a modernised cathedral dedicated to St Cataldo, a dubious 6th-century Irishman said to have been the first bishop of Tarentum, and a castle erected by Charles V. The Mare Piccolo is still famous for its shell-fish, and a considerable portion of the population (1891, 25,246) finds employment in oyster and mussel fisheries. The honey and fruit are still famous also, but the people are to-day as lazy as in Horace's time.

The ancient Tarentum, founded by a body of Spartan emigrants about 708 B.C., grew to be the sovereign city of Magna Græcia. Here flourished about 400 B.C. the philosopher and geometer Archytas, under whom it became the centre of the Pythagorean sect. At the height of its greatness it insolently provoked a quarrel with Rome (281), was saved for a little by Pyrrhus, king of Epirus, but taken in 272, and retaken and punished severely in 207 for revolting to the side of Hannibal five years before. Later it belonged

to Byzantine, Saracen, and Norman masters, sharing the fortunes of the kingdom of Naples.

There is a German history of ancient Tarentum by Döhle (1877), an exhaustive history by De Vincentiis (Naples, 1878 *et seq.*), and a topographical description by Gagliardo (Tarent. 1886).

Tarantula (*Lycosa tarantula*), a species of spider, of a genus to which the name Wolf-spider is often given, a native of the south of Europe. It derives its name from Taranto, where it is very plentiful. It is one of the largest of European spiders, and is a swift hunter. Its bite is much



Tarantula Spider (*Lycosa tarantula*), ¾ natural size.

dreaded, and was long supposed to cause a kind of dancing madness or tarantism; but, although this spider does give a venomous bite (as all spiders do), its powers have been grossly exaggerated.

TARANTISM was a leaping or dancing mania, accompanied with gesticulations, contortions, and cries somewhat resembling those of St Vitus's Dance and other epidemic nervous diseases of the middle ages; but the affection differed from these in several respects, and was doubtless some not then recognised nervous malady, the symptoms of which are plainly those of hypochondriacal and hysterical affections. Although the sufferers were subjected to extraordinary treatment, such as being buried up to the neck in earth, the success of music was apparently so universal and invariable that a class of tunes is said to have been composed, called *Tarantella* or *Tarentella*, to be employed in the cure of the tarantati. The name may, however, have been given to the dance (with pipe and tambourine accompaniment) simply because popular in and near Taranto, and have passed to all musical compositions in the rapid triplet time of the dance. See Hecker, *Epidemics of Middle Ages;* Madden, *Phantasmata;* Bergsoe, *Die Italienische Tarantel.*

Tarapacá, till 1883 the southernmost department of Peru, but annexed by Chili after the war. Area, 19,300 sq. m.; pop. (1891) 47,313. The country contains vast fields of nitrate of soda, as well as silver-mines, deposits of guano, and flocks of sheep, alpacas, &c. Capital, Iquique (q.v.). See W. H. Russell's *Visit to Chile* (1890).

Tarare, a manufacturing town of France, in the dept. of Rhone, stands at the foot of Mount Tarare, 21 miles NW. of Lyons by rail. It manufactures muslins, tarletans, silks, satins, plush, &c. Pop. (1872) 12,888; (1891) 11,738.

Tarascon, a walled town of France, in the Provençal department of Bouches-du-Rhone, 14 miles SW. of Avignon by rail and 8 N. of Arles. King René's castle, dating from 1400, is picturesque and well preserved; and a Gothic church (1187–14th century) is dedicated to St Martha, who here is said to have subdued a dragon. But Tarascon is chiefly famous through associations with the immortal Tartarin. It has manufactures of woollen and silk fabrics, 'sancissons d'Arles,' &c. Pop. (1872) 8479; (1891) 6597.

Taraxacum, or DANDELION-ROOT, a tonic laxative in disorders of the liver. See DANDELION.

Tarazona, an episcopal city of Spain, in the province of Saragossa, 20 miles S. of Tudela, on an affluent of the Ebro. Pop. 8550.

Tarbagatai, mountains, 10,000 feet high, in Russian Central Asia, on the frontier between Semipalatinsk on the north and Chinese Zungaria.

Tarbes, a town in the south of France, capital of the dept. of Hautes-Pyrénées, stands on the left bank of the Adour, 30 miles ESE. of Pau by rail. The cathedral is the principal building. There is a government cannon-foundry in the place, which is the seat of an active general trade. Pop. (1881) 17,744; (1891) 24,784. Tarbes dates from the time of the Romans, and its bishopric was founded in the year 420. It was in the hands of the English in the 13th and 14th centuries.

Tardigrada (Lat. 'slow-paced'), a name given to the group or sub-order of mammals containing the two genera of Sloth (q.v.), remarkable for their sluggish movement and extraordinary tenacity of life under injury, starvation, or poison.

Tare (*Ervum*), a genus of plants of the natural order Leguminosæ, sub-order Papilionaceæ, distinguished from Vicia (see VETCH), to which it is nearly allied, by a cipitate stigma, downy all over. It contains only a few species of weak climbing plants, natives of the temperate parts of the eastern hemisphere. One of these is the Lentil (q.v.). Two (*E. hirsutum* and *E. tetraspermum*), generally known by the name of Tare, are common in cornfields and hedges in Britain. They have very small flowers and pods; the leaves are pinnate, and the leaflets small. They afford nourishing food for cattle. A species of tare (*E. sativum*), with an upright branching habit, is cultivated in some parts of Europe for its herbage, which is used for feeding cattle. The bulk of herbage is considerable, and its nutritious character is high. The leaves have from 8 to 14 pairs of leaflets. The plant thrives well in poor sandy soils. It is not supposed that the *Tare* of the New Testament has any affinity to these plants: it is doubtful what it is, but it seems not improbable that it is the Darnel (q.v.).

Tare and Tret, certain deductions usually made from the gross weight of goods. *Tare* is the weight of the box, cask, bag, or wrapping containing the goods; and the amount is obtained either by weighing the empty package itself, by taking an average of a few similar packages of equal size, or by mutually agreeing upon a certain proportion of the gross weight. The remainder is the *net weight.* Another deduction, at the rate of 4 lb. for every 104 lb., or $\frac{1}{26}$th of the net weight, is then made, as an allowance for waste through dust, &c., and is called *tret.*

Tarentum. See TARANTO.

Target, in its modern sense, is the mark for aiming at in practising with the cannon, rifle, or bow and arrow. In its more ancient meaning a target or targe was a shield, circular in form, cut out of ox-hide, mounted on light but strong wood, and strengthened by bosses, spikes, &c. Of modern targets the simplest is that used for Archery (q.v.). With regard to rifle targets, the spread of the Volunteer movement and the numerous rifle-matches have caused ranges to be constructed over the whole country. Targets are usually painted white and have a black 'bull's-eye' in the centre

(varying from 8 inches diameter in targets at 200 yards to 3 feet at 1000 yards), and a region round this called 'centre.' The accessories are a butt, artificially constructed or cut in the face of a hill, to catch stray shots; a marker's shot-proof cell, near the targets; and a range of such length as can be procured. Previous to the inaugurating of the Wimbledon meeting in 1860 all targets were circular, and made of iron. From that year till 1873 inclusive they were square iron plates; but in 1874 targets of canvas and paper stretched on an iron frame were introduced, together with practice at objects moving at various rates of speed and at a greater or less distance, for which purpose a 'running-man target' was devised, consisting of a millboard figure running on wires, worked by the marker in the butt. There are also self-marking or automatic targets, constructed of several pieces, each of which when struck signals the fact; and disappearing targets, only visible to the firer for very short periods of time. For these and for field firing, targets take the form of flat wooden dummies shaped like men standing or kneeling. Dummies are also used as targets for field artillery practice. Heavy guns firing on a sea-range generally use a floating target, a barrel carrying a flag or a 6-feet-square wooden target on a raft.

Targovica, or TARGOWICZ, a small town in the Russian government of Kieff, was the scene (May 1792) of a plot by five Polish nobles to overthrow the constitution of 1791. See POLAND.

Targum (Assyr. *ragâmu*, 'to speak,' whence *targumânu*, 'speaker'), the general term for the Aramaic versions—often paraphrases—of the Old Testament, which became necessary when, after and perhaps during the Babylonian Exile, Hebrew began to die out as the popular language, and was supplanted by Aramaic (see ARAMÆA).

The origin of the Targum itself is shrouded in mystery. The first signs of it—as an already fixed institution—have been found by some in Nehemiah, viii. 8, and according to tradition Ezra and his coadjutors were its original founders. However this be, there can be no doubt that its beginnings belong to a comparatively early period. The Mishna (q.v.) contains a number of strict injunctions respecting it, and also respecting a certain guild of Meturgemans (whence 'dragoman') or interpreters, who had sprung up as professional followers of those learned men who, at a previous period, had volunteered their services in the translation and paraphrastic interpretation, both activities being implied by the term. At first, and indeed for many centuries, the Targum was not committed to writing, for the same reason that the 'Oral Law' or Halakhah (see EXEGESIS) itself was not at first intended ever to become fixed as a code for all times. In the course of time, however, both had to yield to circumstances, and their being written down was considered preferable to their being utterly forgotten, of which there was no small danger. Yet a small portion only of the immense mass of oral Targums that must have been produced has survived. All that is now extant are three distinct Targums on the Pentateuch, a Targum on the Prophets, Targums on the Hagiographa—viz. on Psalms, Job, Proverbs, the five 'Megilloth' (Song of Songs, Ruth, Lamentations, Esther, Ecclesiastes), another Targum on Esther, one on Chronicles, one on Daniel, and one on the apocryphal pieces of Esther. The most important of the three Pentateuch Targums is the one named after Onkelos, probably a corruption of Akylas (Aquila, a proselyte, one of Gamaliel's pupils), whose Greek version had become so popular that this Aramaic version was honoured with being called after it. This Targum seems to have been originally produced among the scholars of R. Akiba between 150 and 200 A.D. in Palestine, and sent to Babylonia, where it was more needed; wherefore it is called Babli. Here it was probably edited about 300, and afterwards vowelled in the Babylonian method. Subsequently vowelled in the Palestinian method, it spread from Palestine over the world. It is an excellent translation for the people, and adheres more closely to the Massoretic text than any other ancient translation. It is useful for the exegete, the linguist, and the antiquary.

Two other Targums on the Pentateuch have hitherto been known as Targum Jonathan ben Uzziel and Targum Jerushalmi. They are of Palestinian or Syrian growth. Jerushalmi is fragmentary, and appears to be a Haggadic supplement to Onkelos. The Pseudo-Jonathan, by its maturer angelology, its abbreviations, and other signs, appears to be a later recension of the Jerushalmi. It cannot well have been composed before 750. As a version this Targum is of small importance; but it is valuable as a storehouse of allegories, parables, sagas, and the like popular poetry of its time. Its language and grammar are exceedingly corrupt; it abounds, moreover, with foreign—Greek, Latin, Persian, and Arabic—terms. It mentions Constantinople (Numbers, xxiv. 19, 24); and names Khadija and Fatima (Genesis, xxi. 2). Its general use lies more in the direction of Jewish literature itself, as well as of archæology and antiquities of the early Christian centuries, than in that of a mere direct interpretation of the Bible text. The Targum on the Prophets is generally and erroneously ascribed to Jonathan ben Uzziel, an eminent scholar of Hillel the Elder; the fact being that, except one spurious Talmudical passage, in which mention is made of his having translated the Prophets, this Targum is everywhere else, from the Talmud down to the authorities of the 10th century, ascribed to one R. Joseph, president of the Babylonian academy of Sora about 322. This Targum, while tolerably literal in the first—the historical—books, gradually becomes a frame for Haggada, which it introduces at every turn and at great lengths. It is considerably interpolated, containing historical bits disguised, or rather typified, lyrical pieces of some poetic value, and much Messianic lore. In language and general manner it resembles Onkelos, which evidently lay before the author.

Joseph the Blind, to whom the foregoing Targum is ascribed, is the reputed author of Targums on the Hagiographa. Several centuries lie between him and them, their date being approximately between 800 and 1000. Certain distinctions between the different books must further be made. The Targums on Psalms, Job, and Proverbs were probably contemporaneous compositions due to private enterprise in Syria. The two former are made more paraphrastic than the last, which resembles closely the Syriac version. The paraphrase on the five 'Megilloth' mentions the Mohammedans, and is of later date; probably one man's work. It is principally a collection of more or less poetical fancies, traditions, and legends, to which the single verse in hand merely seems to furnish the keynote. Its dialect lies somewhat between the East and West Aramaic. The Targum on the Book of Chronicles —almost unknown until it was printed in the 17th century—also belongs to a late period, and was probably composed in Palestine. There are some useful philological, historical, and chiefly geographical hints to be gleaned from it, but nothing more; least of all can it be used exegetically. A Persian version of a Targum on Daniel (unedited) is all that has been discovered on that book as yet. It was probably composed in the 12th century, the

influence of the early Crusades being plainly visible in it. On the paraphrase of the apocryphal pieces of Esther we shall not dwell here, any more than on the scanty fragments of a 'Palestinian Targum' that are found either interspersed in the general (Babylonian) Targum, or as independent pieces. It seems probable that more of this Palestinian version will come to light some day, as authorities of a few centuries back still quote from it rather largely. At present, however, their quotations are nearly all that is known. By 900 in Africa and Spain the Targum had begun to be disused in public, Arabic or the national language being substituted. In Yemen the Aramaic Targum is still used in the ancient manner, the meturgeman standing beside the reader and rendering verse by verse.

The Targum of Onkelos unvowelled was first printed in Bologna, 1482; vowelled, Lisbon, 1491; more or less incorrect in the Bomberg Rabbinical Bible of Venice (1518) and in subsequent editions; the Complutensian Polyglot (1517); the Biblia Regia of Antwerp (1569); and Walton's Polyglot (Lond. 1657). Buxtorf's edition (1618–19) is vitiated by attempts to conform it to biblical Aramaic. Sabionetta's edition (1557) is the best till Abr. Berliner's reproduction of this (Berlin, 1884), with an exhaustive essay. The Targum on the prophets appears in the Bomberg, Complutensian, Antwerp, Buxtorf, and Walton Bibles. It is edited by Paul de Lagarde (Leip. 1872). He edited the Targum on the Hagiographa (1873). See Frankel, *Zu d. Targum der Propheten* (Breslau, 1872); Pauli, *Chaldee Paraphrase on Isaiah* (Lond. 1872); the *Targum of Onkelos and Jonathan on the Pentateuch* (1862 and 1865), by Etheridge.

Tarifa, the southernmost town on the continent of Europe, is a seaport of Spain, in the province of Cadiz in Andalusia, and is situated 21 miles SW. of Gibraltar. The town is still quite Moorish in aspect, and retains its alcazar and battlemented Arab walls. A causeway connects it with a small island, on which are some powerful fortifications and a lighthouse, 135 feet above sea-level. Tunny and anchovy fishing is and has been since Roman times the principal occupation of the inhabitants, but the preparation of leather is also carried on, and there is a trade in sweet oranges. Tarifa, called Julia Joza by Strabo, was occupied in 710 A.D. by the pioneers of the Moorish invasion, under Tarif Abû-Zor'a, whence it obtained its Arabic name of Jezîret-Tarîf (Tarif's island). It was taken from the Moslems, after an obstinate siege, in 1292, by Sancho IV. of Castile, and its first Spanish governor was Alonzo Perez de Guzman, celebrated in the Romancero for his valiant defence of the town against the besieging Moors in 1294. During the Peninsular war Tarifa was successfully defended by Gough with 1800 British troops and 700 Spaniards against a besieging army of 10,000 French (December 1811 to January 1812). Pop. 13,580.

Tariff (from the town of Tarifa, where, during the rule of the Moors in Spain, duties were collected), a table or catalogue, generally drawn up in alphabetical order, of the duties, drawbacks, bounties, &c. charged or allowed on different kinds of merchandise, as settled by authority, or agreed to between different states. The principles of the tariffs of different countries depend on their respective commercial policy, and on the fluctuating interests and wants of the community. They may be prohibitory, retaliatory, or differential; and may be assessed *ad valorem*, &c. See Customs, Free Trade, Protection.

Tarik. See Gibraltar.

Tarim River. See Turkestan (Eastern); and Asia, Vol. I. p. 486.

Tarlatan, a thin, gauze-like fabric of cotton, used for ladies' ball-dresses, &c. It is either finished white or dyed or printed in colours. Tarare is the chief centre of this manufacture; the Swiss tarlatans are inferior.

Tarlton, Richard, a famous clown of Queen Elizabeth's day, who died in 1588, and on whom was fathered a well-known Jest-book (q.v.).

Tarn, a dept. in the south of France, bounded on the N. by the depts. of Aveyron and Tarn-et-Garonne, receives its name from the river Tarn, an affluent of the Garonne. Area, 2217 sq. m.; pop. (1881) 359,223; (1891) 346,739. The surface is in general elevated, and in the south and south-east are the Montagne Noire and the Lacaune branches of the Cévennes. Wooded mountains, vine-clad hills, beautiful valleys, and fertile or grass-producing tracts are the principal features of the landscape. A considerable part of the surface is covered with forests, chiefly of oak and beech. The dept. is for the most part agricultural, grain, wine, fruit, potatoes, chestnuts, and cattle being amongst the chief produce. Coal is mined; and wool-spinning, silk-spinning, dyeing, the making of steel goods, glass, and pottery are local industries. Tarn is divided into four arrondissements—Albi, Castres, Gaillac, and Lavaur; Albi is the capital. See the work on the dept. by Bastié (1876–77).

Tarn-et-Garonne, a small dept. in the south of France, bounded on the SE. by the dept. of Tarn. Area, 1436 sq. m.; pop. (1881) 217,056; (1891) 206,596. The principal river is the Garonne, with its affluents the Tarn and Aveyron. The surface is largely occupied by plateaus, about 1000 feet in average altitude; the highest hills do not rise above 1600 feet. The climate is temperate. Cereals are raised, also wine, fruit, hemp, &c.; there are some manufactures of silk, paper, candles, and soap. The dept. is divided into the three arrondissements of Montauban, Castelsarrasin, and Moissac; Montauban is the capital. See a work by Moulenq (1879–85).

Tarnopol, a town of Austrian Galicia, on the Sereth, 80 miles ESE. of Lemberg by rail. Pop. (1890) 26,097, half being Jews.

Tarnow, a trading town of Austrian Galicia, 50 miles E. of Cracow by rail. It has a theological college and a fine cathedral. Pop. 27,694.

Taro (*Colocasia macrorhiza*, or *Arum esculentum*), a plant of the natural order Araceæ, of the same genus with the Cocco (q.v.) or Eddoes, and cultivated for its roots, which are a principal article of food in the South Sea Islands. They are washed to take away their acridity, and cooked in the same way as bread-fruit; they may also be boiled or made into pudding. A pleasant flour is made of taro. The plant has no stalk; broad, heart-shaped leaves spring from the root; and the flower is produced in a spathe. The leaves are used as spinach. See Hawaii.

Tarots. See Cards.

Tarpan. See Horse, Vol. V. p. 793.

Tarpaulin, strong linen or hempen cloth, coated with tar or pitch to render it waterproof. An elastic pitch from bone tar or stearine residues is used by tarpaulin makers.

Tarpeian Rock. See Capitol.

Tarpon (*Megalops atlanticus*), a food-fish of America belonging to the Clupeidæ or herring family, is common in the warmer Atlantic waters and off the shores of the Gulf states, and attains a length of 6 feet. It is sometimes called Jew-fish.

Tarquinii. See Corneto.

Tarquinius, the family name of two kings of Rome, derived from the Etruscan city of Tarquinii—and doubtless implying the domination of that city over a district south of the Tiber. The first, Lucius Tarquinius Priscus, is said to have

reigned at Rome 616–578 B.C., and to have considerably modified the constitution, and to have begun the Servian agger and the Circus Maximus.—Lucius Tarquinius Superbus (534–510), the seventh and last king of Rome, was a capable but intolerable despot, the chief events of whose reign are given at ROME (Vol. VIII. p. 787). See LUCRETIA.

Tarragon, an aromatic plant (*Artemisia Dracunculus;* see WORMWOOD) used for flavouring vinegar, sauces, &c.

Tarragona, a seaport of Spain, chief city of the modern province of Tarragona, situated on the Mediterranean shore, at the mouth of the Francoli, 60 miles W. of Barcelona by rail. The upper and older town is irregular and dirty, and is girdled with ramparts; the lower is regular and open, and defended by two forts. The Gothic cathedral dates from about 1120. The industries are spinning and weaving (chiefly in silk, also in jute), felt and lace making. But of much greater importance is the shipping and transport trade. The annual tonnage of ships that enter reaches half a million, and the imports and exports reach over thirty million *pesetas* respectively. Pop. (1887) 27,225. Tarragona, the Roman *Tarraco,* was the capital of the Roman province of Tarraconensis. Among the Roman antiquities are the remains of an amphitheatre, which has been used as a quarry; a magnificent aqueduct, still used, 96 feet high and 700 feet long; and near the town the Tower of the Scipios, much decayed. Tarragona was taken by storm by the French under Suchet in 1811, but in August 1813 its fortifications were blown up by him when unable longer to hold out against the English.

Tarrytown, a village of New York, on the Hudson, 21 miles by rail N. of New York City. It has some manufactures. Close by Major André was captured in 1780; and two miles to the south Washington Irving spent his last years, and there lies buried. Pop. (1890) 3901.

Tarshish, probably the same as *Tartessus,* the Latin form for the Greek name of a city and emporium of the Phœnicians in Spain, near the mouth of the Guadalquivir, but used of the whole region—subsequently known as Andalusia (q.v.). It is frequently mentioned in Scripture. Speaking of Tyre, Ezekiel (xxvii. 12) says—'Tarshish was thy merchant by reason of the multitude of all kinds of riches;' notably there were here great fisheries of tunny and murænа, and rich mines of silver and other metals. Others contend that Tarshish was simply Tarsus; and some have thought a part of Yemen was meant, near Ophir (q.v.).

Tarsia-work. See INLAYING.

Tarsipes, a small Australian honey-sucking marsupial, of the family Phalangistidæ, about the size of a mouse. See MARSUPIALS, PHALANGER.

Tarsus, anciently chief city of Cilicia, and one of the most important in Asia Minor, on the river Cydnus, 12 miles from the sea, in the midst of a productive plain. It was a great emporium for the traffic carried on between Syria, Egypt, and the central region of Asia Minor. In the time of the Romans two great roads led from Tarsus, one north across the Taurus by the 'Cilician Gates,' and the other east to Antioch by the 'Amanian' and 'Syrian Gates.' Tarsus, which was sacred to Baal Tars, and is thought by some to have been founded by Sennacherib 690 B.C., was probably of Assyrian origin, but the first historical mention of it occurs in the *Anabasis* of Xenophon, where it figures as a wealthy and populous city, ruled by a prince tributary to Persia. In the time of Alexander the Great it was governed by a Persian satrap; it next passed under the dominion of the Seleucidæ, and finally became the capital of the Roman province of Cilicia (66 B.C.). At Tarsus Antony received Cleopatra, when, as Aphrodite, she sailed up the Cydnus, with magnificent luxury. Under the early Roman emperors Tarsus was as renowned for its culture as for its commerce, Strabo placing it, in respect to its zeal for learning, above even Athens and Alexandria. The natives were vain and luxurious; a Moslem general estimated their number at 100,000. Weaving goats' hair was the staple manufacture. It was the birthplace of the apostle Paul (q.v.), who received the greater part of his education here; the Stoic Antipater and the philosopher Athenodorus were also natives, and here the Emperor Julian was buried. Gradually, during the confusions that accompanied the decline of the Roman and Byzantine power, it came into the hands of the Turks, and fell into comparative decay; but even yet this modern, squalid, and ruinous city, under the name of *Tarso* or *Tersus,* has a permanent population of 7000, and a pop. of 30,000 in winter, and exports corn, cotton, wool, gall-nuts, wax, goats' hair, skins, hides, &c.

Tartan. See HIGHLANDS.

Tartar, a mixture of bitartrate of potash and tartrate of lime, is a deposit formed from wine, and known in its crude form as Argol (q.v.). The name, given by the alchemists, is usually referred to Gr. *tartaros;* but some derive it from Arab. *durd,* 'dregs.' For Cream of Tartar, &c., see TARTARIC ACID. For tartar on the teeth, see DENTISTRY; for tartar emetic, ANTIMONY.

Tartaric Acid, $C_2H_2(OH)_2(COOH)_2$, exists free or in combination with bases in the fruits and juices of many plants. In the rowan, grape, and pine-apple it gives a subacid flavour. The commercial source is *tartar,* which is boiled with chalk, and the insoluble tartrate of lime is removed by straining. On treatment with sulphuric acid and purification, tartaric acid is obtained in the form of large transparent, prismatic crystals, which are readily soluble in water. They possess a pleasant acid taste, and the solution reddens litmus. When rubbed in the dark the crystals become luminous. When tartaric acid is heated it melts, forming the isomeric metatartaric acid, and by further heating it is broken up into a number of bodies, formic acid, acetone, and carbonic acid being among the number.

Besides the tartaric acid of commerce there are others, isomeric with the above, known to chemists. These differ mainly in the power of deviating the plane of Polarised Light (q.v.) to the right or the left. The ordinary acid deviates it to the right, and another deviates it to the left, so that when mixed in equal proportions and dissolved the solution has no action on polarised light at all. Such a compound exists in nature, and is known as *racemic acid.* It gave rise to many important researches and discoveries, owing to its similarity to tartaric acid, except in its being inactive to polarised light. To Pasteur is due the above explanation of its peculiar behaviour. Tartaric acid is largely used in dyeing and calico-printing, and in the manufacture of aerated waters and confections. Being a dibasic acid (see ACIDS), it forms a large number of salts, many of which are important. *Bitartrate of potash,* or *cream of tartar,* $KHC_4H_4O_6$, is obtained by purifying the crude argol by crystallisation. It is used, along with baking soda, by housewives, as a baking powder. Medicinally it is a useful purgative, and is a favourite domestic remedy for clearing the blood in spring-time. *Tartarated iron* or *tartrate of iron and potash* is a mild tonic, which, when dissolved in sherry, constitutes iron wine. *Tartrate of potash and antimony,* or *tartar*

emetic, $KSbOC_4H_4O_6$, has been long used in medicine, in doses of $\frac{1}{10}$ to $\frac{1}{4}$ of a grain; it is a powerful sudorific, but in larger doses, 1 to 3 grains, it acts as an emetic. It has gained considerable notoriety through being employed in several famous poisoning cases which have come before the public. It should never be in unskilful hands, as $\frac{3}{4}$ grain has proved fatal to a child, and 2 grains in one case at least were fatal to an adult.

Tartars (better TATARS), originally certain Tungusic tribes in Chinese Tartary, but extended to the Mongol, Turkish, and other warriors, who under Genghis Khan and other chiefs were the terror of the European middle ages. The name, originally Turkish and Persian *Tátar*, was doubtless changed to Tartar, either consciously or unconsciously, because they were supposed to be like fiends from hell (Gr. *tartaros*, 'hell'). The term is used loosely for tribes of mixed origin in Tartary, Siberia, and the Russian steppes, including Kazan Tartars, Crim Tartars, Kipchaks, Kalmucks, &c., and has no definite ethnological meaning. In the classification of languages Tartaric is used of the Turkish group. See the articles TURKS, MONGOLS, and TURANIANS.

TARTARY (properly TATARY) is the name under which, in the middle ages, was comprised the whole central belt of central Asia and eastern Europe, from the Sea of Japan to the Dnieper, including Manchuria, Mongolia, Chinese Turkestan, Independent Turkestan, the Kalmuck and Kirghiz steppes, and the old khanates of Kazan, Astrakhan, and the Crimea, and even the Cossack countries; and hence arose a distinction of Tartary into European and Asiatic. But latterly the name Tartary had a much more limited signification, including only Chinese Turkestan and Western Turkestan.

Tartarus, according to Homer, is a deep and sunless abyss, as far below Hades as earth is below heaven, and closed in by iron gates. Into Tartarus Zeus hurled those who rebelled against his authority, as Kronos and the Titans. Afterwards the name was employed sometimes as synonymous with Hades or the under-world generally, but more frequently for the place of damnation where the wicked were punished after death. See HELL.

Tartini, GIUSEPPE, a celebrated Italian musician and composer, born at Pirano in Istria in 1692. At Padua he studied in the first instance for the church, and subsequently for the law, but gave up both for music and fencing. Having secretly married the niece of the Archbishop of Padua, he had to take refuge in a monastery at Assisi, where he became a proficient on the violin. In 1721 he was allowed to rejoin his wife, and return to Padua, where he was appointed solo violinist in the chapel of San Antonio—a highly honoured position, which, along with the fees from his pupils, secured him a fair income. He died in 1770, and a statue in his honour was erected in Padua. Tartini 'was one of the greatest violinists of all time, an eminent composer, and a scientific writer on musical physics.' His best-known work is the famous sonata, *Il Trillo del Diavolo*. He was the author of *A Treatise on Music*, and was the discoverer of the so-called grave harmonics, or third or combination sounds in sounding double stops.

Tartuffe, the name of the chief character in Molière's most celebrated comedy, which has become a synonym in all languages for a hypocritical pretender to religion. See MOLIÈRE.

Tarudant, capital of the Moorish province of Sus, on the Sus River, about 40 miles from the sea. Pop. 8500.

Tashkand, or TASHKENT, the capital of Russian Turkestan, stands 300 miles to the NE. of Samarcand, on a small river which empties itself into the Syr-Daria or Jaxartes. It consists of an ancient walled city and a new European quarter with broad streets bordered by canals and avenues of trees. The Russian citadel lies a little to the south. There are extensive military stores, official buildings, Russian schools of all grades, an observatory and geographical society, Russian and Kirghiz newspapers, and a brisk trade with Russia and other parts of central Asia. It is connected with the European system of telegraphs, and with Samarcand by a railway (laid in 1895-97), ultimately to be extended to the Siberian line; and it has manufactures of silk, leather, felt goods, and coarse porcelain. Pop. 100,000, including 80,000 Sarts (q.v.) and 15,000 Russians. Tashkand was in 1810 conquered by Khokand, and since 1868 has been Russian. See TURKESTAN.

Tasmania, the island state of the Commonwealth of Australia (1901), approximately corresponds in latitude and longitude with southern France and northern Italy in the northern hemisphere; and occupies an area of 26,215 sq. m.—about that of Scotland. It is bounded on the N. by Bass Strait, while its other coasts are swept by the waters of the great Southern Ocean. It may be assumed with reasonable safety that Tasmania was at one, if a remote, period a constituent part of the continent of Australia. It is confirmatory of this that the great Cordillera range (as Sir Roderick Murchison termed it), which is traceable along the eastern border of Australia across Torres Straits to New Guinea, may similarly be traced across Bass Strait by the chain of islands which almost continuously links Tasmania with Australia. See map at SOUTH AUSTRALIA.

Although it possesses wide stretches of comparatively level plains and tableland, the prevailing characteristics of Tasmania are those of a mountainous country. It has within its borders fifty mountains of heights from 2500 feet upwards, whereof the loftiest is Cradle Mountain (5069 feet); the higher tiers are snow-capped through the winter and suggestive of Switzerland or the Tyrol. Its streams (which are perennial) are as to their gravelly, boulder-strewn bed, their environments of hill and foliage—even as to their trout and salmon, as the rivers and burns of Scotland. The lakes, notably Lake St Clair, are suggestive of a Loch Katrine or Loch Lomond on a large scale. The lakes of Tasmania, hitherto neglected save by the very occasional tourist or angler, should in the course of time become summer-resorts and sanatoria for the whole people of Australasia. The Great Lake is about 90 miles in circumference. It is a peculiar feature of these lakes that they are found upon an elevated plateau averaging more than 3000 feet above sea-level. The extent of this plateau, from Dry's Bluff in the north-west to Denison Range in the south-west, is over 60 miles, while from Dry's Bluff two other plateaus branch (1) to Cradle Mountain, a distance of nearly 50 miles, and (2) to Table Mountain, over 43 miles.

Tasmania has many rivers, but of these only the Derwent, Tamar, Gordon, Pieman, and Huon are navigable for many miles from their mouths for ships of fair size. The Derwent is thus navigable for over 60 miles—i.e. 22 above Hobart, the capital; Launceston, the northern city, stands at the head of navigation on the Tamar.

Hobart is the principal harbour of Tasmania, and is second to none in the southern hemisphere. The Launceston port has been improved by dredging so as to admit of large ocean steamers mooring at its wharves. At Emu Bay harbourage for large vessels has been secured by a breakwater, and on that portion of the coast-line (the north-

west), as well as on the east, north-east, and south coast, there are many harbours for small craft. The west coast has but one harbour worthy of the name—Macquarie Harbour, a noble sheet of water fed by the Gordon and other streams, but, like the river-ports of the north, a bar harbour, requiring an expenditure of some £180,000 in dredging the mouth, &c. before it will admit vessels of large tonnage.

The character of the soil varies very considerably. In the north-western, north-eastern, midland, and south-eastern divisions, where settlement has mostly taken place, the plains and valleys have been enriched by extensive outbursts of basalt with accompanying tuffs, which have produced a very rich chocolate soil. Here the associations are those of the ancient Tertiary lake systems. Towards the extreme west and south granites, metamorphic mica, and quartzose schists, with overlying slates, grits, and limestone of Cambro-Silurian age, reappear again and again in anticlinal and synclinal ridges which trend north and south. These rocks may also be seen following the south coast and evidently occupying nearly all that extensive mountain-region to the south of the river Huon.

The western vegetation as compared with that of the east presents as marked a contrast as do the prevailing rocks upon which it flourishes. The most remarkable trees are the Eucalypts. Many of these are known to exceed 280 feet in height, with a girth of from 40 to 50 feet, and one is mentioned whose height was estimated at 330 feet. Lady Franklin's tree, near Hobart, is stated to have a circumference of 107 feet at a height of 4 feet from the ground. These Eucalypts have a substantial value as timber-trees, and a considerable trade is done in the hard-wood boards, palings, &c. sawn or split from them. But the most valuable trees are the blackwood, Huon pine, King William pine, and musk, all of which furnish highly ornamental woods that are beginning to make their way in the English market. The most picturesque trees of a Tasmanian landscape are the magnificent tree-ferns that lend the glories of tropical foliage to many a stream and gully, and the wattle, with its delicate and fragrant mimosa-like bloom. It is worthy of note that all Tasmanian trees and shrubs are evergreens.

The *fauna*, like the *flora*, of Tasmania is almost identical with that of Australia. Of the forty-six species of terrestrial mammals inhabiting the island two belong to the Monotremata, of which order the platypus or ornithorhynchus is the most remarkable. There are twenty-seven representatives of the Marsupialia or pouched animals, nine of which are peculiar to Tasmania, the most remarkable of these being the Tasmanian devil (see DASYURE) and the hyæna-like native tiger (see THYLACINE). The bats have four representatives. Of rodents there are thirteen, of which the most conspicuous is the common water-rat or yellow-bellied musk-rat (*Hydromys chrysogaster*). Comparatively few birds are peculiar to the colony, though there are in all 187 indigenous species. For the sportsman there are four varieties of quail, four of pigeons, nine of snipe and curlew, ten of plovers, and twelve of black swans, Cape Barren geese, and wild duck. For the epicure there is the wattle-bird (family Melyphagidæ). Reptiles are few and not of a deadly character. There are three snakes: the tiger or banded snake (*Hoplocephalus curtus*), the copper-headed snake (*H. superbus*), and the whip-snake (*H. coronoides*). All these are in a greater or less degree poisonous, and human beings are occasionally bitten, but the death of a human being from snake-bite has not occurred for many years. There are seventeen species of lizards, all small and harmless; and at rare intervals a small scorpion (probably just imported) is met with. Sea and fresh-water fishes (including the seven species of salmon, salmon-trout, and trout brought from the United Kingdom and successfully acclimatised) number 213 species, about one-third of which are good edible fish. It is known that large shoals of sand smelts, sprats, and anchovies appear upon the coasts at regular seasons, but because of the lack of proper appliances to catch them, these escape capture. And, in the absence of proper curing establishments, large quantities of such fish as are caught have been wasted at times, although there has been, and is, a ready market for them in Australia, the trumpeter and other fishes of the Tasmanian waters being unknown in the warmer regions of the north.

Natives (in the sense of aborigines of Tasmania) there are none. There are a few half-castes, the descendants of European sealers by native *gins*, and these are found with one exception on the islands of Bass Strait; but the aboriginal Tasmanian has died out—the last male in 1869, the last female in 1876. It is probable that there were never more than 5000 of these people. It is certain that they were a very inferior race, and it was a logical, if cruel, consequence of their contact with Europeans that they should disappear off the earth. That they were inferior even to the low order of humanity found on the mainland is proved by the comparative poorness of their resources for sustaining existence; the Tasmanian was as far behind the Pacific Islanders in regard to civilisation as those islanders are behind the European of the 19th century. The Tasmanian was a savage, suspicious, treacherous, and untamable. He first came into collision with the early French explorers. Blood continued to flow during the racial war waged between the natives and the early British settlers. But this was not quite a war of extermination; in 1830 an effort was made to save the race; the remainder of them were induced to come into a settlement where they were carefully provided for, with the untoward result that slowly but surely this remnant of a people died out.

The climate is peculiarly temperate and genial. The difference between the mean temperature of summer and winter is 15°. The meteorological observations of Hobart give a maximum of 96·3 against 92·2 recorded at Greenwich, and a minimum of 32·0 against 15·5. It is cooler on the hills, and it is more equable at other places in the plains, notably at Circular Head, where the maximum has never risen above 78° or the minimum fallen below 34°. Snow is very rarely seen except on the mountains. The rainfall varies considerably in different localities. A mean of thirty-five to forty years gives as the result for Hobart 22·93 inches; on the east coast and some parts of the midlands it is probably less; on the north-west and north-east, where timber-clad hills more abound, it is greater; and on the west coast, where the prevailing wind off the Southern Ocean meets a barrier of ranges often clothed with forest to their summits, it is greatest of all. The average for the island as a whole may be put down at something like that of England; but the amount of sunshine recorded in Tasmania is very materially in excess of that of Great Britain. The air is drier, the atmosphere clearer, and the extremes of heat and cold less trying than in the mother-country.

Tasmania was discovered in 1642 by Abel Jans Tasman (*c.* 1602–59), who was despatched by Antony Van Diemen (1593–1645), governor-general of the Dutch settlement in Batavia, on an expedition in search of the 'Great South Land.' Until 1798 it was regarded as a portion of New Holland (or Australia); but in that year Lieutenant Flinders and

Dr Bass explored the strait which divides the continent from Tasmania, and which was named after the adventurous doctor. Curiously enough, while the early explorers ignored this dividing strip of water, they imagined a north and south dividing stream which cut Australia into sections, and it was over the portion to the east of this imaginary stream that Holland for some years boasted of a shadowy sovereignty.

Subsequent to the discovery of 1642 Tasmania was visited by French and English explorers in 1772, 1773, 1777 (Captain Cook's third and last expedition), 1789, 1792 (when Lieutenant Bligh, notorious for the mutiny of his crew, paid his second visit), 1793, 1794, 1798, and 1802. On the 12th September 1803 the first settlement was made by Lieutenant Bowen, acting under instructions from Governor King of New South Wales. Tasmania was the second colony founded in Australasia, that of New South Wales (or Port Jackson) having been founded fourteen years before. The first settlement in Victoria was made by Tasmanian colonists in 1834–37, and Tasmania may therefore claim the honour of being the mother of Victoria. For many years sheep-farming was the principal industry. The merino stud-sheep, for which the colony is now renowned, are possibly the direct descendants of the lambs, originally drawn from the royal stud at Kew, imported in 1820. These sheep have been exported to other colonies continuously for many years, and with a value for one year of £66,743; and as much as 1125 guineas has been realised as the price of one ram.

Whaling in the south seas was largely carried on from Hobart for some years. In 1848 thirty-eight whalers sailed from Hobart, and in 1869 twenty-three; but by 1891 Hobart's whalers had dwindled down to two, though whales in that southern region have not died out.

Tasmania (as Van Diemen's Land) was originally a penal settlement. In 1852 transportation to this colony was abolished; and now all traces of the convict element have died out. In 1855 Tasmania was the first colony of Australasia to receive the privileges of local representative government. The population in 1881 was 115,705; in 1891 it had increased (by 27 per cent.) to 146,667.

While Tasmania has made relatively immense strides since 1860 as an agricultural colony, the industry that has most stimulated the hope of her people is mining. From shore to shore gold, silver, tin, copper, coal, and many other minerals are found, sometimes in wide-spread fields, at other times in more restricted areas. Gold in any quantity was only obtained in 1867, and tin, first discovered in 1871, was not found in quantity for export until 1874. In 1898 there were in force 486 gold, 441 silver, and 205 tin mining leases. The value of the gold exported in 1897 was £230,282; of silver, £216,893; and of tin, £150,586. Owing to the cessation of alluvial gold-mining, the number of persons employed in this industry has decreased, being 1461 in 1896. The total output of coal in 1897 amounted to 42,530 tons. Copper ore and iron pyrites were exported to the value of £317,437 in 1897. Of the exports (1897) from Tasmania, £807,433 went to Victoria, £583,273 to New South Wales, and £289,369 to the United Kingdom—the latter largely wool, £181,134, and fruit, £74,917. The chief imports from the United Kingdom in the same year were: apparel and haberdashery, £71,374; iron, wrought and unwrought, £37,562; cottons, £65,065; woollens, £40,863.

Of the total area of Tasmania (16,778,000 acres), up to 1898, 4,768,901 acres had been taken up by settlers, and 833,575 acres leased as sheep-runs. The amount of wheat and oats grown increased from 871,490 bushels in 1894 to 2,770,626 bushels in 1898; fruit is a very important crop; hay, potatoes, and hops are also grown in large quantities.

The total imports were, in 1897, £1,367,608, and the total exports, £1,744,461. The registered shipping amounted, in 1897, to 155 sailing-vessels and 44 steamers, with a total tonnage of 14,376; while 699 vessels, with a tonnage of 542,049, entered the ports, and 717 of 542,189 tons cleared, about two-thirds being from and to Hobart. The total revenue was, in 1897, £845,019, and the expenditure, £785,026; and the public debt was £8,390,026, nearly all raised for public works. In 1898 there were 495 miles of railway open for traffic. The telegraph system belongs to the government, and in 1898 there were 1884 miles of line in operation, with 225 stations; there is also a submarine cable connection with the Australian continent. There are 570 miles of telephone wires, with exchanges in Hobart, Launceston, New Norfolk, and Zeehan. Education is compulsory, and there are 282 public elementary schools and 173 private schools, besides secondary and technical schools and a university. The defence of Tasmania is provided for by a force of volunteers, consisting of two rifle regiments, engineer, artillery, and auxiliary forces, with a total complement of 1779 officers and men.

Tassisudon, the capital of Bhutan (q.v.).

Tasso, BERNARDO, now chiefly remembered as the father of the great Torquato, was, however, held in high esteem as a poet in his own day. Born at Venice in 1493, he belonged to an illustrious family of Bergamo, who had held the administration of the posts in Italy and other countries, and hence show in their armorial bearings a post-horn and the skin of a badger (*tasso*), of which fur the post-horses' frontlets were made. Bernardo, left an orphan, studied at Padua, where he gained the friendship of the famous Cardinal Bembo, the then oracle of literary taste, and, becoming secretary of Guido Rangone, was sent to France (1528). Here he entered the service of Renée, daughter of Louis XII. of France, wife of Ercole II. d'Este, reigning Duke of Ferrara, and mother of the Alfonso and Leonora d'Este whose influence was to be so great on the future destiny of Bernardo's famous son. A few years later we find him in the service of Sanseverino, prince of Salerno, whom he followed in many travels, joining with him the expedition of the emperor, Charles V., against the Tunisian pirates in 1535, and visiting Spain, Flanders, and France a second time.

Bernardo's literary productions had been chiefly lyrical, of the bombastical and hyperbolic type affected by the imitators of Petrarch; he had followed the movement made at this time to adapt Italian verse to Latin metrical forms. Sanseverino settled on him a pension and allowed him to retire to Sorrento, there to dedicate himself to the composition of an epic poem, the subject

of which was the Amadis of Gaul and his adventures, as described in the admired Spanish romance by Ordonez de Montalvo (published about 1492). Bernardo married, probably in 1536, Porzia de' Rossi, belonging to a noble family from Pistoja in Tuscany. In 1537 a daughter, Cornelia, was born to them, and in 1544 their only son, Torquato, the future great poet. Bernardo and his wife lived in perfect peace and unity, until in 1547 their prosperity came to a sudden end. Their protector Sanseverino resisted the attempt of the imperial viceroy to establish the Inquisition in Naples, fell into disfavour with the emperor, Charles V., and, joining the French king, was outlawed and had his estates confiscated. Poor Bernardo, who had followed his patron, was included in the same sentence. His wife and children took refuge in Naples with relatives; his little son was sent to him in Rome in 1554. For some years Bernardo led a wretched life there, still more embittered by the loss of his beloved wife, who died in sorrow and poverty in Naples, 1556. He found a refuge later at the court of Urbino, where he finished his epic, *L'Amadigi*. Bernardo went to Venice to superintend the publication of his great work (4to, 1560), but it did not bring him the fame he had hoped. The last years of Bernardo's life were passed in the service of Duke Guglielmo Gonzaga of Mantua, who made him podesta of Ostiglia. Here, on the 4th September 1569, he ended his long and troubled career, breathing his last in the arms of his beloved son. Bernardo's chief work, *L'Amadigi*, is now entirely forgotten; it is one of the many imitations of Ariosto's romantic epic, but exaggerated and inflated in style and unreal in sentiment; the verse, however, is skilful and melodious. He began another epic, *Floridante*, finished by his son, and published (1587, 4to). Besides his numerous lyrics (2 vols. 1749) he has left a copious and interesting correspondence (1733–51).

See the more recent *Lettere di Bernardo Tasso*, edited with biography by G. Campori (Bologna, 1869), and, for details of his later years, *Lettere inedite* (published by Portioli, Mantua, 1871).

Tasso, TORQUATO, son of the preceding, was born at Sorrento, near Naples, 11th March 1544. He was one of the greatest of Italian poets, though belonging to a time of decadence, to that later 16th century which saw the decline of art and literature, and religious and political liberty in the peninsula crushed under the power and bigotry of Spain. After his father was exiled Torquato lived with his mother, the exemplary Porzia de' Rossi, in Naples, and received his earliest instruction at the Jesuit school there. In 1554 he joined his father in Rome, never again seeing his unfortunate mother, who died, broken-hearted, two years later.

He showed great precocity in his studies, read Latin and Greek fluently at an early age, and composed with ease both prose and verse in Italian. He shared his exiled father's wandering life; increasing his store of learning under his careful supervision at Pesaro, Urbino, and Venice. In 1560 Tasso was sent to study law and philosophy at Padua, and while there composed and published his first work, a romantic poem in twelve cantos, *Rinaldo*, which he dedicated to the Cardinal Luigi d'Este. In 1565 Tasso entered the service of this cardinal, and by him was introduced to the splendid court of his brother, Alfonso II. d'Este, reigning Duke of Ferrara. The youthful poet was appreciated and encouraged by the sisters of the duke—Lucrezia, afterwards Duchess of Urbino, and Leonora—two princesses renowned even amongst the cultured women of that day for their many brilliant gifts. Amid such congenial surroundings Tasso began his great epic poem and masterpiece, *La Gerusalemme Liberata*.

In 1571 he accompanied the Cardinal d'Este to France, and was received with favour by Charles IX. and his mother, Catharine de' Medici; and he was warmly welcomed by his brother-poets, chief amongst whom was Ronsard. On his return to Italy in the following year Tasso became definitely attached to the service of Duke Alfonso at Ferrara. This court had been the scene of the earliest revival of the profane drama in Italy towards the end of the 15th century, and it was for this celebrated stage that Tasso wrote in 1573 his beautiful pastoral play, *Aminta* (1581). The perfection of its style, moulded on classic models, and the melody of its verse won for this exquisite dramatic poem a wide popularity and many imitators. Tasso completed his great epic in 1575, and (like his father before him) submitted it before publication to the judgment of the distinguished savants and critics of the day. Their fault-finding (sometimes just, but pedantic and mixed with religious scruples) and Tasso's replies (never rebellious, and generally yielding, though always full of judgment and fine literary taste) are all recorded in his correspondence and in his *Apologia* of the poem. These conflicting considerations and discussions coming after his long poetical labours seem to have unhinged his sensitive and highly-strung mind, and in 1576 he showed the first signs of the mental disorder which darkened all his later days. He became suspicious, melancholy, and particularly oppressed by the idea that he had offended against the church and been denounced to the Inquisition. On the 18th June 1577 Maffeo Veniero writes to the Grand-duke of Tuscany: 'Of Tasso I give you news that yesterday evening he was imprisoned for having, in the chamber of the Duchess of Urbino, drawn his knife on a serving-man, but he was arrested rather because of his disorder and to cure it than as a punishment. He is of a strange humour, believing himself to have sinned as a heretic, and also has the fear of being poisoned.' After this outbreak the succeeding years of his life are one long chronicle of mental struggles and sufferings of every kind. His first confinement lasted only a few days, and he shortly afterwards fled from Ferrara. Wandering through Italy on foot, he made his way to Naples, where he was affectionately cared for by his sister, Cornelia; but even here he found no rest. He travelled to Rome, and northwards through the principal towns until he reached Turin, on foot and so poorly accoutred and strange in appearance that the guards refused him admittance until recognised by a former friend as the great poet. He was then honourably entertained by the Duke Carlo Emanuele of Savoy. His great longing was to return to Ferrara, the scene of his early triumphs and brightest memories, and in 1579 he seized the occasion of Duke Alfonso's second marriage to present himself anew at that court. He met with a cold reception, and deeply wounded by some real or imagined slight he broke in public into furious invectives against the duke, his courtiers, and all the world. On the 15th March of the same year he was confined by order of the duke in the hospital of St Anna in Ferrara, and there he remained a prisoner for seven years. During these miserable years he produced many noble verses and philosophical dialogues, and a vigorous defence of his *Jerusalem*, the publication of which, without his leave and with many errors, had sorely grieved him. His many piteous letters of appeal to his friends and patrons, from the pope downwards, for release from prison give a most complete and heart-rending picture of his sufferings at this time. The sad figure of the good, gentle, and great poet in a madhouse, while his famous epic was

delighting Italy and all Europe, is one of the most pathetic in literary history, and one which may well interest posterity, even without the romance of his supposed passion for the Princess Leonora, a passion so often alluded to by later poets (especially Goethe, Goldoni, and Byron). There seems to be no positive proof that the unhappy poet nourished any other sentiment for the princess than that of the respectful devotion, admiration, and gratitude natural towards such a patroness. Certainly no manifestation of presumptuous love for the princess was the cause of his imprisonment; all contemporary accounts of his state point to his insanity, bearing the character of religious mania. But doubtless whatever may have been the nature of his feelings to Leonora her death in 1581 must have been a new grief to him. During her fatal illness Tasso writes from prison to her chaplain: 'If my Lady Leonora is better, as it comforts me to believe, and I greatly desire, humbly kiss her hands in my name, most reverend father, letting her know that I have grieved much for her illness, the which I have not bewailed in verse, because of I know not what tacit repugnance of my mind.'

Duke Alfonso had been repeatedly petitioned to set Tasso free. The cruel contrast between his fate and the daily growing fame of his great poem (which had been reprinted six times in a few months) had greatly excited popular interest. At length in July 1586, by the intercession of the Prince Vincenzo Gonzaga, Tasso was liberated, and at once left Ferrara, never to return. He followed his new patron to Mantua, where he remained a year, and where he wrote a tragedy, *Torrismondo*, his only and not very successful effort of that kind. Broken in health and spirits, he began again his restless wanderings from town to town, spending, however, most of these later years in Rome and Naples, where he tried in vain to recover from his mother's relatives some part of her inheritance, or from the government his father's confiscated estates. He was, however, helped and protected by many kind friends and patrons eager to show honour to so great and unfortunate a genius. He busied himself in rewriting his great epic, according to the modifications proposed by his numerous critics; he tried to observe more strictly the classic unities and historical accuracy, to remove profane episodes and to treat more of religion and theology. The result, a poor spectre of his living masterpiece, even the style and verse being inferior, was published under the name *Gerusalemme Conquistata* (Rome, 1593, in 4to), and dedicated to Tasso's latest patron, Cardinal Cinzio Aldobrandini, nephew of Pope Clement VIII. By this pope he was summoned to Rome to be crowned on the Capitol as poet-laureate, like Petrarch. The ceremony, however, never took place, for on Tasso's arrival in the papal city his already weakened health became worse, and he retired to the care of the monks of Sant' Onofrio, a quiet convent on the Janiculum, where, resigned and peaceful, he breathed his last on the 25th April 1595.

Tasso, although not the last great poet that Italy has produced, is certainly the last whose influence made itself felt throughout Europe, and his *Jerusalem* is the culminating poetical product of his age, as Dante's *Divine Comedy* and Ariosto's *Orlando* are of the two preceding centuries. In our own literature we find traces of his influence notably in Milton. His great poem is, like himself, a typical product of his time, with its blind idolatry of classic forms conflicting with newly-revived religious superstition and bigotry, but exempt from the current defects of hypocrisy, affectation, and licentiousness. As Settembrini says: 'One thing Tasso had, which few in his time possessed, a great heart, and that made of him a true and great poet, and a most unhappy man.' The sincere fervour of his piety and purity of his life are testified by his own writings and by his contemporaries. Tasso's intention was to create in his *Jerusalem* a great religious epic, his theme was to be the triumph of the warriors of the Cross in the first Crusade, and his hero was to be Godfrey of Bouillon, their commander, his material to be taken from *Historia belli sacri verissima*, by Tyrius (Basel, 1559–64). With the history of his nominal hero the poet has entwined fictitious characters and episodes, and it is these creations which give vitality to his work. The melodious verses, in which he has sung the loves of the fair Erminia and the warlike Clorinda and the beauty and wiles of the enchantress Armida, still live on the lips of the Italian people—verses whose authorship seemed to the diseased conscience of poor Tasso a sin to be repented.

Tasso's earliest biographer was his personal friend, the Neapolitan G. Manzo, the same Manzo whom Milton visited in Naples, and to whom he dedicated a Latin poem. This friend thus describes Tasso's appearance (*Vita di T. Tasso*, 1619): 'He was of tall stature and well proportioned, his complexion of perfect whiteness, the colour of his thick hair and beard between dark and fair, his head large, his forehead square, his eyebrows and lashes black, his eyes large and blue, his nose aquiline, his lips thin and pale, and his limbs so agile that he yielded to none in fencing, riding, and jousting.' More complete than any biography is the picture which is given of his outer and inner life in his copious correspondence in his dialogues and various prose-works, where he reveals himself as a most facile and eloquent prose-writer.

Among Tasso's many commentators and critics we find his great contemporary, Galileo (see the *Scritti di Critica litteraria di Galilco*, Turin, 1889). The earliest complete edition of the *Gerusalemme Liberata* is that of Bonna (Ferrara, 1581, 4to); the best modern reprints are those at Modena (1868) and at Florence (1889). Translations of the *Jerusalem* have been made into many languages; in English the most famous is that of Fairfax (1600; new ed. by H. Morley, 1891); others are by Bent, Broadhead, Robertson, Smith, Wiffen, and Sir J. K. James (1868; new ed. 1884). The most complete biography is the *Vita di Tasso*, by Serassi (Rome, 1783, 4to; reprinted Florence, 1858); more recent is *Studii su T. Tasso*, by Ferrazzi Bassano (1880). See also Tasso's letters and prose writings (edited by Guasti, 1854–57); D'Ovidio, *Saggi Critici* (1879), and Corradi, *L'Infermita di Tasso* (1881); *Letteratura Italiana*, by Settembrini (Naples, 1887); *Cours de Littérature de Lamartine* (1863); *Life of Tasso*, by Black (Edin. 1810); *Life of T. Tasso*, by Dean Milman (Lond. 1850, somewhat antiquated); and Miss E. J. Hasell, *Tasso* (Foreign Classics series, 1882).

Taste, one of the special senses (see SENSATION). The parts of the mouth affected by sapid substances are the surface and sides of the tongue, the roof of the mouth, and the entrance to the pharynx. The mucous membrane is invested by stratified squamous epithelium, which, over the surface of the tongue, covers little vascular projections termed papillæ. One can see the papillæ of the sides and upper part of the tongue with the naked eye, as little sharp or rounded projections; the latter, thickly clustered at the tip and sides, may appear, if the system is out of order, as little red points like those of a strawberry. In the cat tribe the papillæ are hard and curved backwards into the mouth, so that the animal can use the tongue as a scraper to remove the flesh from the bones of its prey. The pointed papillæ are termed 'filiform,' and one is repre-

sented in fig. 1, while a rounded papilla is seen in fig. 2. They are essentially the same in structure, differing alone in shape and size, and, were the figures drawn to some common scale, fig. 2 would have to be three or four times as big as it is. At the back of the tongue are some eight or ten papillæ of quite a different nature, called 'circumvallate.' They are arranged to form a V

Fig. 1.

a, artery; *v*, vein; *c*, capillary loop; *e*, epithelium; *f*, hair-like processes at the apex.

with its angle pointing backwards. These are hardly papillæ at all, but may be looked upon rather as tiny patches of mucous membrane trenched out from the surrounding parts. Into these trenches Ebner's glands secrete a watery albuminous fluid, keeping them perpetually moist and free from foreign particles. In the epithelium lining these trenches curious little bodies called taste-bulbs are lodged; and, as these are the parts which are probably more especially concerned in taste, they must be carefully described. Each taste-bulb looks like a flask-shaped barrel or box, the walls of which are composed (fig. 4) of flat elongated epithelial cells fitted side by side like the staves of a cask. The taste-bulbs open each by a little pore into the trench, and into the deeper part a nerve enters in the way represented in fig. 3. The cask is probably for the protection of the sensory cells which it contains,

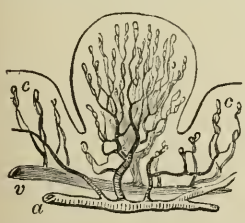

Fig. 2.—A Fungiform Papilla, with the capillary loop of its simple Papillæ injected:
a, artery; *v*, vein. Around the base there is often a groove, which is here shown; as also the capillary loops, *c*, *c*, of two of the neighbouring simple papillæ (magnified 18 diameters).

and one of which is drawn in *d*, fig. 4. These cells are much elongated, and end each in a tiny bristle which projects with those of their companion cells from the little pore into the trench, and is here moistened by the juice of Ebner's gland and whatever sapid substance may be present. The impressions which these sensory cells receive from the bristles, say by the action of a bitter like 'hops,' is carried by the delicate nerve which starts from the opposite end of the cell out of the taste-bulb directly to the brain. Within each taste-bulb are other cells (*e*, fig. 4), which separate and support the sensitive cells, and are similar to analogous structures seen in the sensory epithelium of the eye, and nose, and ear. While it is almost certain that these taste-bulbs are organs of taste, it is not equally certain that other parts are not involved. The reason for this belief is that in the front and sides of the tongue these taste-bulbs are few in number, while in these regions taste sensations are pretty acute. It is therefore not improbable that the nerves which abundantly pass into the epithelium of the tongue end in other ways, but unfortunately we are at present much in the dark concerning their exact method of termination. It is to be noted that the protective layer of the mucous membrane is thin, and might conceivably be permeated readily by the juices of the mouth, which would reach the lower cells into which some of the nerves certainly pass. From the mucous membrane of the mouth the impressions produced by sapid substances are carried probably by fibres belonging to the fifth nerve. These fibres, although they belong to this nerve, are found to run in the greater part of their course in other nerve trunks—viz. the glosso-pharyngeal, to the back of the mouth and tongue, and the chorda tympani to the front of the tongue.

Having sketched the mechanism concerned in the production of taste sensations, we can now turn to the discussion of the many interesting facts which may be observed when this mechanism is called into play. In the first place, it may be remarked that substances capable of dissolving in the juices of the mouth are alone tasted. Marble, wood, flint, are devoid of taste, and so is pure starch; these are all of them quite insoluble in water. By the aid of various means we can convert the last-named substance into a very soluble 'dextrine,' yet this is tasteless. Another chemical product of the starch is a soluble substance termed 'dextrose,' which has a sweet taste and is commonly termed 'grape-sugar.' These examples will serve to illustrate the general fact that substances to be tasted must be in solution, though not all soluble substances are capable of giving rise to this sensation. It is a matter of general experience

that, if a substance like sugar be simply placed in the mouth and allowed to dissolve, its taste is only faintly evident. If, however, the juices of the mouth, sweetened by the sugar, be rubbed into the mucous membrane by moving the tongue against the palate, the sensation is greatly intensified. One invariably 'smacks the lips' in trying to appreciate the qualities of a taste, and obtains in this way its maximum effect.

A fact that is hardly known by the laity is that most of the so-called tastes are really 'smells.' Sugar, salt, quinine, and some acids are devoid of smell; we could not distinguish them except by the tongue itself, and we have in these the prime taste sensations of sweet, salt, bitter, and acid. Meat, wines, and fruit are smelt, not tasted, and a bad cold dulls our appreciation of these articles of diet. To the prime taste sensations already mentioned may be added perhaps alkaline, astringent, and metallic tastes, but when all is told this organ yields us rough results when compared with smell, sight, or hearing, whereby hundreds and thousands of shades of quality are readily perceived in the odour of flowers, the lights from coloured objects, and the sounds from an orchestra. The various taste sensations are not equally produced on stimulating the whole of the gustatory area, and indeed each taste seems to have some special locality at which it is most acutely felt. If we take a piece of quassia or a hop-leaf and chew it, we shall at first be unconscious of taste, and it is only when the juice of the mouth laden with these bitter principles passes to the back of the mouth that the taste is felt at all. This is why we drink beer in the draught, and do not sip it like wine. The sweet or acid wine is tasted best by the front part of the tongue, while the bitter beer is only appreciated as it is going down the throat. As in the other senses, anything that stimulates the gustatory nerve gives rise to a sensation; and although sapid particles effect this best of all, electrical or even mechanical stimuli have some effect. If we place a piece of zinc and copper on the tongue, and join them so as to give rise to a feeble current, or still better, if a slight interrupted electrical current be passed through the mucous membrane of the tongue, metallic saline tastes are produced. These are possibly due to electrolytic changes and not to direct stimulation, though this is less likely to be the case with the induced currents, equally powerful in the production of sensation. It is often stated that a sharp tap on the tongue produces a sweet or saline taste; this is, however, an experiment which often fails. If we rub the back and side of the tongue with the finger tip we shall hardly fail to notice a bitter taste, and it is probable that we shall question the cleanliness of the finger used. A scrupulously cleaned glass rod gives rise, however, in equal measure to the same sensation, and we are forced to conclude that the mechanical stimulus of the rod calls forth that taste which has its seat in the back of the mouth and tongue.

Our knowledge of what really takes place when an external agency affects the senses, sets up a nerve-motion which travels to the brain and there induces a sensation, is very limited. Perhaps in the case of hearing our knowledge is most precise, and there are grounds for believing that the sound-waves mechanically set in motion appropriate structures within the ear, just as a note sung before the piano will cause certain of its strings to vibrate. The light affects the eye in a manner at which we are at present only guessing; but it can be said that our different colour sensations depend upon the stimulation of the retina by ether vibrations of different pitch and complexity. In this respect then sight and hearing are both alike, and we have outside the body media capable of vibrating at different periods, and the kind of vibration determines the kind of sensation produced. As to taste and smell, until lately nothing whatever was known which would explain in any rational way their production. When Newlands, Lothar Meyer, and Mendeleëff discovered what is termed the Periodic Law in chemistry, it occurred to the author of this article to see if this law holds good for taste and smell; this was found to be the case (see *Proceedings* of the Royal Society of Edinburgh, 1885–86; and *Brain*, 1886). Newlands found that if we arrange the elements in a series, beginning with that one which has the lowest and passing to that which has the highest atomic weight, a periodic recurrence of function or property is found. There is a general resemblance in physical properties between the first, eighth, fifteenth, &c., and between the second, ninth, sixteenth, &c. Those elements picked out of the series from their resemblance and periodic recurrence Mendeleëff arranged in groups (see ATOMIC THEORY), and the author found that similar compounds of these elements have similar tastes. To take an example (group 1), the chlorides of lithium, sodium, potassium, rubidium, cæsium are all salt, while the sulphates of these elements are all saline bitters. It is evident that this group of elements, similar in their physical properties, can also produce similar tastes, and we can correlate taste a physiological effect with some common physical quality.

Carnelly has shown that salts of elements belonging to the same group, if coloured, have colours which are related in this respect, that as we ascend the group the colour always approaches more and more to the red end of the spectrum. This, as it is unnecessary to point out, indicates molecular vibration of similar and related pitch, and in this case, alike in taste, smell, hearing, and sight, we have this common fact, that the stimulus is vibratory, and associated with the kind of this vibration is the quality or kind of sensation produced. Another very curious point is that, as in the case of hearing and smell, both very high and very low vibrations are unfelt. Bodies like albumen and starch are devoid of taste, even when converted into very soluble peptone and dextrine. When these molecules are broken up, then sapid substances may be produced such as sugar. Substances such as water and watery solutions of gases, like high-pitched notes or the ultra-violet rays of the spectrum, are incapable of producing sensations, and sulphuretted hydrogen on the border-land has a faint acid taste. Like smell, the sense of taste is placed at the entrance of the alimentary canal, and affords us knowledge of the nature of the food about to be eaten. We have so far adapted ourselves to our environments that, as a rule, those substances which please these senses are salutary foods, and the converse is equally true. This is, however, a rule with many exceptions, and it is perhaps one of the most anxious parts of a child's training, that of teaching by the eye those natural products which are injurious or even of a poisonous nature.

Tatars. See TARTARS.

Tate, NAHUM, was son of Faithful Tate, D.D., and was born in Dublin in 1652. He had his education at Trinity College, Dublin, succeeded Shadwell as poet-laureate in 1690, is described by Oldys as 'a free, good-natured, fuddling companion,' and died August 12, 1715, in the precincts of the Mint at Southwark, then a sanctuary for debtors. His writings include ten dramatic pieces, one of them an adaptation of *King Lear; Panacea, or a Poem on Tea;* various birthday odes, and an elegy on the death of Queen Mary; *Miscellanea*

Sacra; the *Innocent Epicure, or Art of Angling.* But his name alone survives from the metrical version of the Psalms, which he executed in conjunction with Nicholas Brady (q.v.). The whole was completed as early as 1696, and slowly made its way into general use in the Church of England, supplanting the older version made in the reign of Edward VI. by Sternhold (q.v.) and Hopkins. The work as a whole was poor, but portions are not without poetic quality. The *Supplement to the New Version* (1703) was most probably the work of Tate alone; one thing in it, 'While shepherds watched,' has travelled over the Christian world.

Tati. See MATABELELAND.

Tatian, a Christian apologist born early in the 2d century (110, Zahn), was an Assyrian by birth, studied Greek philosophy, and wandered as a sophist round the Roman world, but about 150 at Rome was won to Christianity by the simple charm of the Old Testament Scriptures and the example of the purity and courage of the Christians. He became a disciple of Justin, in whose lifetime he wrote his *Oratio ad Græcos* (ed. by Otto, Jena, 1851; by Schwartz, Leip. 1888), a glowing and uncompromising exposure of the faults of heathenism as compared with the new 'barbarian philosophy.' After Justin's death (166) Tatian fell into evil repute for heresies, and he retired to Mesopotamia, probably Edessa, writing with characteristic fearlessness and vigour treatise after treatise, all of which have perished. He was certainly infected with Gnostic notions of the universe, the supreme God, the demiurge, and the world of æons; but the notions of his which gave most offence were his excessive asceticism, his rejection of marriage and animal food, and adoption of the practices of the Encratites. His name became a synonym for all manner of dangerous and unsettling tendencies, and his doctrines were assailed in turn by Irenæus, Tertullian, Hippolytus, Clement of Alexandria, and Origen. Neither the place nor date of his death are known, but it took place perhaps at Edessa, and probably about 180. Of his writings one maintained a place of importance in the Syrian Church for two hundred years, and supplies one of the most interesting chapters in the history of sacred literature. This was the *Diatessaron*, a gospel freely constructed out of the four gospels known to us, not a harmony in the modern sense, but a kind of patchwork gospel, its principle *amalgamation* not *comparison* in Lightfoot's phrase. This Harnack thinks was written in Greek, but Zahn and most other scholars, among them Lagarde, Bäthgen, Lightfoot, and Hilgenfeld, in Syriac. There is no mention of the *Diatessaron* in any Latin writer before the middle of the 6th century, when Victor of Capua attributes an anonymous gospel harmony he had found to Tatian, neither Cassiodorus, Gelasius, Jerome, Augustine, or Juvencus so much as naming it. Of Greek writers the first to mention it is Eusebius: 'Tatian composed a sort of connexion and compilation, I know not how, of the gospels: and called it τὸ διὰ τεσσάρων. This work is current in some quarters even to the present day.' Zahn thinks from this that Eusebius had never himself seen it, but, knowing Tatian to have been a heretic, thought his compilation a mere distorted gospel like that of Marcion and Gnostic teachers. Epiphanius says, 'the Diatessaron gospel is said to have been composed by him [Tatian]. It is called by some the gospel according to the Hebrews.' But on Syrian soil in Theodoret, bishop of Cyrrhus, near the Euphrates, we first find (453) an explicit account of the book: 'He [Tatian] composed the gospel which is called *Diatessaron*, cutting out the genealogies and such other passages as show the Lord to have been born of the seed of David after the flesh. This work was in use not only among persons belonging to his sect, but also among those who follow the apostolic doctrine, as they did not perceive the mischief of the composition, but used the book in all simplicity on account of its brevity. And I myself found more than two hundred such copies held in respect in the churches in our parts. All these I collected and put away, and I replaced them by the gospels of the four evangelists.' Thus we see that in the 5th century this work was used in the Syrian churches as the form in which the gospel was read, and further back still we find evidence of its use in the 3d-century *Doctrine of Addai* (Cureton's *Ancient Syriac Documents*, 1864, and G. Phillips, Syr. and Eng. ed. 1876), and in the *Homilies* of Aphraates (fl. 340) and the famous Ephraem Syrus. The Syriac text of the Homilies of the former was edited by Professor Wright in 1869, and Zahn has proved that the key to the difficulty of his gospel citations is the fact that he used the *Diatessaron*. Bar-Salibi, a Syrian bishop (12th cent.), distinctly states that Ephraem wrote an exposition of Tatian's *Diatessaron*. Lightfoot printed his famous article on Tatian (*Cont. Rev.* May 1877), ignorant of the fact that a year before Dr Moesinger of Salzburg had published at Venice a Latin translation of the same commentary, made as early as 1841 by Father Aucher of the Mechitarist monastery of San Lazzaro from the Armenian edition of Ephraem's works published in 1836 (4 vols.). The first scholar to make this remarkable discovery widely known was Ezra Abbot in his *Authorship of the Fourth Gospel* (1880). Next year Westcott noticed it in the 5th ed. of his *History of the N. T. Canon*, and Professor Wace began his admirable series of articles in the *Expositor*.

Aucher and Moesinger believe this Armenian version to have been made about the 5th century, and to be a translation from the Syriac, and from the whole facts of the case the constructive argument is so strong that we may without hesitation accept this as the work of Ephraem, and conclude that the basis of this commentary is a gospel harmony, and that the *Diatessaron* of Tatian.

Again, the Latin harmony of Victor of Capua, as it still exists in the *Codex Fuldensis* (pub. by Ranke, 1868), on examination was found to be substantially identical with the fragments of Ephraem. In 1881 Zahn published his masterly monograph on Tatian's *Diatessaron*, containing a reconstruction of the text from the Latin, based on Moesinger's Latin version of Ephraem's Commentary, on the quotations in Aphraates, and occasional parallels with the *Codex Fuldensis*. He showed that Tatian's original Syrian text agreed in great part with the Curetonian Syriac, and evidently preceded the Peshito or reformed Syriac text. The fresh interest thereby aroused in the question led Ciasca of the Vatican Library to examine anew the Arabic MSS. there. The existence of one was already known, it having been partially described by Assemani, Rosenmüller, and Akerblad. In 1886 Antonios Morcos, vicar-apostolic of the Catholic Copts, forwarded to Rome a 9th-century MS., which Agostino Ciasca edited for the jubilee of Pope Leo XIII., and this was found both in contents and arrangement to correspond with the work edited by Moesinger.

Harnack thus sums up the conclusions that may be drawn from what may be considered as proved: (1) In Tatian's time there was still no recognised N. T. Canon, and the texts of the gospels were not regarded as inspired; (2) about 160 our four gospels were already in existence and authoritative, and the fourth on an equality with the three synoptics; (3) the text of the gospels in 160 was

substantially the same as it is now, save that intentional changes and interpolations were made later, as the passage about the church being built upon Peter the rock.

See J. H. Hill, *The Earliest Life of Christ; The Diatessaron of Tatian* (translation and notes, 1893); Zahn, *Forschungen zur Geschichte des neutestamentlichen Kanons* (1881–91), and *Geschichte des neutest. Kanons* (1891); *Texte und Untersuchungen zur Geschichte der Altchristlichen Literatur*, by O. von Gebhardt and A. Harnack (Bd. iv. 1888); the admirable summary of the history of the *Diatessaron* and all the facts relating to it, by the Rev. Professor Samuel Hemphill (Dublin, 1888); and the Study by Professor J. Rendel Harris (1890); Harnack's article in the *Ency. Brit.*, W. Möller's in Herzog's *Real-Encyklopädie*, and Professor Moore's in the *Journal of Biblical Literature* (1890); also Hilgenfeld, *Die Ketzergeschichte des Urchristenthums* (1884).

Tatius, ACHILLES, one of the Greek romancers whose date may be safely put before the middle of the 4th and after the beginning of the 3d century A.D. He belonged to Alexandria, and was much influenced by the rhetorical school of poetry, which owned Nonnus as its master. Suidas tells us that he became not merely a Christian, but a bishop, after writing his romance of *Leucippe and Cleitophon*, but the accuracy of this may well be doubted. Further it is more than doubtful whether he was the author of treatises on etymology and astronomy. His romance comes next to the *Theagenes and Chariclea* of Heliodorus in time, and perhaps in merit. The author describes himself as gazing at the picture of Europa in the temple of Venus in Sidon, when he is accosted by Cleitophon, who straightway tells him his whole adventures in eight books. The plot is sadly lacking in probability, and grows positively wearisome towards its long drawn out conclusion. Its artistic development is marred by the introduction of much irrelevant discourse on painting, sculpture, and natural history, and moreover much of this is mere wordy rhetoric. The delineation of character is feeble to a degree—the hero a mere shadow of a man, uninteresting in everything save devotion to his mistress, who is much better drawn in every respect. Still the dawn of love in Cleitophon's heart is well described, and the doubts and fears characteristic of the passion are well realised, and reveal a striking knowledge of the human heart. Many of the situations are worse than indelicate, but the morality of the purpose, so characteristic of the Greek romances even in their indecencies, is evident throughout. The Greek is elegant, yet unaffected.

Editions are in the *Erotici Scriptores Græci* by Hirschig, Le Bas, and Boissonade (Paris, 1856), and Hercher (Leip. 1858–59); also separately, by F. Jacobs (Leip. 1821). There is a French translation in Ch. Zévort's *Romans Grecs* (Paris, 1856); an English, by the Rev. R. Smith in Bohn's Classical Library (1855). See A. Chassang, *Histoire du Roman dans l'Antiquité Grec. et Lat.* (Paris, 1862); E. Rohde, *Der Griech. Roman und seine Vorläufer* (Leip. 1876); and Dunlop's *History of Prose Fiction*, edited by Henry Wilson (2 vols. 1888.)

Tattersall's, a celebrated mart in London for the sale of racing and other high-class horses, and one of the principal haunts of racing men, so called from Richard Tattersall (1724–95), a native of Hurstwood in Lancashire, who came early to London, entered the service of the second Duke of Kingston, and ultimately became an auctioneer. In 1766 he took a ninety-nine years' lease from Lord Grosvenor of premises in Hyde Park Corner, and after its expiry Tattersall's was removed to Knightsbridge Green (1867). In 1779 Richard Tattersall bought the famous horse Highflyer of Lord Bolingbroke for £2500, and named his house at New Barns near Ely Highflyer Hall. Here he was often visited by the Prince of Wales from Newmarket. The prince was also a joint-owner with 'Old Tatt' in the *Morning Post*, and lost thereby £10,000, which was paid to Tattersall's heirs in 1810. See *Memories of Hurstwood* (Burnley, 1889), by Tattersall Wilkinson and J. F. Tattersall.

Tattooing, the custom of marking the skin with figures of various kinds by means of slight incisions or punctures and a colouring matter. The word itself is Tahitian (*ta*, 'a mark'), but the practice is very widely spread, being universal in the South Sea Islands, and also found among the North and South American Indians, the Dyaks, the Burmese, Chinese, and Japanese, and common enough still among civilised sailors. The absence upon the claimant of tattooed marks known to have been upon the body of Roger Tichborne was a point of much importance in the famous Tichborne trial. It is expressly forbidden in Scripture (Lev. xix. 28), from which we may conclude it was common amongst the neighbouring nations. Undoubtedly the main cause of its origin was the desire to attract the admiration of the opposite sex, but this fundamental human desire does not of course exclude motives for tattooing for religious or other ceremonial purposes, or for mere ornament apart from sexual considerations. Among the Polynesians the operation is attended with circumstances of ceremony, and the figures represented are often religious in signification or symbolic of rank, not seldom the *totem* or special tribal badge. The New Zealanders were distinguished by elaborate tattooing of the face, and many of their heads are preserved in European museums. As it was formerly a common custom for shipmasters to purchase these on visiting New Zealand there is little doubt that the demand stimulated the supply. Dr Wuttke labours to prove that tattooing is a kind of writing, but, whatever may be the case elsewhere, its origin in Japan, where it reached its greatest perfection, is neither ceremonial nor symbolical, but merely cosmetic. Its end is to take the part of a garment or decoration, those parts of the body only being tattooed which are usually covered, and only in the cases of such workmen as runners, grooms, bearers, who work in a half-nude state. Still further, this is found only in large and civilised towns where nudity might have been objectionable. It was a substitute for clothing, but now that clothing is compulsory in Japan it has lost its meaning, and may be expected to disappear. Dr Baelz, writing in 1885, estimated that a few years before there were in Tokio alone as many as 30,000 men who were tattooed. The head, neck, hands, and feet are never tattooed, and it is found among the lower classes alone, and very seldom amongst women, and these only the dissolute. The usual objects illustrated are large dragons, lions, battle scenes, beautiful women, historical incidents, flowers—never obscene pictures. The colours employed are black, which appears blue, derived from Indian ink, and various shades of red, derived from cinnabar. The artist uses in his work exceedingly fine sharp sewing-needles, fixed firmly four, eight, twelve, twenty, or forty together, and arranged in rows in a piece of wood. The points are quite even, except when it is desired to produce a light or dark shading. A skilful artist can cover the whole back or breast

Tattooed Maori Chief.

and belly of a grown man in a day, and that with excellent pictures with various degrees of shading. These punctures are not very painful, and as soon as the operation is over the patient is bathed with hot water, which brings out the colour more clearly. Among the Ainos again the tattooing is done on the exposed parts of the body, and largely practised by women. The Igorrotos in the mountainous region above Luzon tattoo elaborately, but in series of lines and curves. They ornament the hands, arms, breast, and part of the legs, the back only in one tribe, and a favourite form is a picture of the sun as a number of concentric circles on the back of the hand. According to the Archduke Joseph of Austria, tattooing is unknown amongst the Gypsies, but this is questioned by Bataillard and MacRitchie.

Many savages paint their skins as a means of protection against cold, or against the sun's heat or the bites of insects; others again attempt thus to make their aspect more terrible in war, as Cæsar tells us did the ancient Britons. Tattooing has often been employed as a badge of brotherhood in some cause, and more often still as a means of identification for slaves and criminals. The so-called branding of the letters D. and B.C. on military deserters and incorrigible characters, only given up in 1879, was merely tattooing with needles and Indian ink. Among the relics of the ancient cave-men of Europe are hollowed stones in which were ground the ochre and other colours for painting themselves. The war-paint of the ancient Briton and Red Indian braves still survives in the paint-striped face of the circus-clown; and the rouge of the faded London beauty is merely the civilised equivalent of the Maori women's tattooing round the mouth, or the beautiful flower-patterns on the backs and bellies of the Formosans. Amongst the lower-class criminal population in Europe the practice of tattooing is still common, but almost exclusively amongst males, more than twenty designs being sometimes found on the same individual—transfixed hearts, swords, serpents, flowers, initials, a woman's figure, and occasionally obscenities. Among 800 convicted French soldiers Lacassagne found 40 per cent. tattooed, many with inscriptions which gave an index to the criminal's attitude to the world.

See Wuttke, *Die Entstehung der Schrift* (1872); Lacassagne, *Les Tatouages* (Paris, 1881); Baelz, in *Mittheilungen der deutschen Ges. für Völkerkunde* (1885); W. Joest, *Tätowiren* (Berlin, 1887); and General Robley, *Moko or Maori Tattooing* (180 illustrations, 1896).

Tauchnitz, Karl Christoph Traugott, a famous German printer and bookseller, was born at Grosspardau, near Leipzig, October 29, 1761. Bred a printer, he set up in 1796 a small printing business of his own in Leipzig, with which he shortly after conjoined publishing and typefounding, and all his enterprise only added to his prosperity. In 1809 he began to issue editions of the Greek and Latin classics, the elegance and cheapness of which carried them over the learned world. He was the first to introduce (1816) stereotyping into Germany, and he also applied it to music. On his death, 14th January 1836, the business was continued by his son, Karl Christian Phil. Tauchnitz (1798–1884).—A nephew of the elder Tauchnitz, Christian Bernhard, Baron von Tauchnitz, born at Schleinitz, 25th August 1816, also founded in 1837 a printing and publishing house in Leipzig. In 1841 he began his well-known collection of 'British Authors,' of which 2600 volumes appeared within the first fifty years. The enterprising publisher was ennobled in 1860, and made a life-peer in 1877, and died Aug. 13, 1895.

Tauler, Johann, German mystic, was the son of a wealthy citizen of Strasburg, where he was born about 1300. His education was entrusted to the Dominicans in Strasburg and Cologne. When Tauler was twenty-four years of age the clergy of his native city, where he then lived, were prohibited from performing the religious services in consequence of a papal interdict having been launched against Strasburg, because it took a different side from the pope in a disputed imperial election. Tauler, however, and his colleagues continued to officiate. But the heads of the order forbidding them to do so, the magistrates banished the Dominicans from the city. For some seven years or so Tauler found refuge in Basel, where coming in contact with the Friends of God, a sort of free association for deepening religious life, his views underwent a great change. Some ascribe this 'conversion' to Nicholas of Basel; others discredit the fact altogether; whilst others again admit it, but dispute the identity of the agent. At all events, from this time forward Tauler became the centre and source of the quickened religious life in the valley of the middle Rhine, his repute as an eloquent and earnest preacher spreading far and wide. His banishment over, he returned to Strasburg, and is believed to have stayed behind there during the Black Death, to minister to the sick and sustain the courage of the living. He died in 1361. Prior to his conversion Tauler seems to have been a disciple of Master Eckhart (q.v.), at whose feet he probably sat when a young student, and thus he belongs to the Mystics (q.v.). The change that took place in him at Basel turned his thoughts from speculative thinking to pious exhortation and practical doing; and it is this note of sincere practical piety that especially distinguishes his *Sermons*, which are reckoned amongst the finest in the German language. Another work of a more speculatively mystical tendency, *Following in the Footsteps of Christ*, is by some attributed to Tauler.

See K. Schmidt, *Johann Tauler* (1841); Denifle, *Das Buch von geistlicher Armut* (1877); Ritschl, in *Zeitschrift für Kirchengeschichte* (1880); Miss Winkworth, *Tauler's Life and Sermons* (Lond. 1857).

Taunton, a pleasant, well-built town of Somersetshire, in the fair and fertile valley of the Tone ('Taunton Deane'), 45 miles SW. of Bristol. Here about 710 Ine, the West Saxon king, built a fortress, which, passing with the manor to the bishops of Winchester, was rebuilt by Bishop William in the first quarter of the 12th century. Added to in the 13th and 15th centuries, this castle received Perkin Warbeck (1497), and was held by Blake (q.v.) during his famous defence of the town (1644–45). In its great hall, fitted up now as a museum, Judge Jeffreys opened the 'Bloody Assize,' hanging 134 and transporting 400 of the inhabitants of Taunton and the neighbourhood who had accorded Monmouth an enthusiastic welcome (1685); and here too Sydney Smith made his 'Mrs Partington' speech (1831). The church of St Mary Magdalene has a noble Perpendicular tower 153 feet high (*c.* 1500; rebuilt 1858–62); and other buildings are the Elizabethan shire-hall (1858), the municipal buildings (formerly the grammar-school founded by Bishop Fox in 1522), King's College school (1880), Independent college (1847–70), Wesleyan Institution (1843), Huish schools (1874), Bishop Fox's girls' school, hospital (1809–73), barracks, &c. Formerly one of the great 'clothier towns' of Somerset, Taunton now has shirt, collar, glove, and silk manufactures, with a large agricultural trade. It was thrice chartered (1627, 1677, 1877) as a municipal borough, and lost one of its two members in 1885. Pop. (1851) 14,176; (1891) 18,026.

See works by Toulmin (2d ed. 1822), Cottle (1845), Macmullen (1860–62), Jeboult (1873), and Pring (1880).

Taunton, capital of Bristol county, Massachusetts, at the head of navigation on Taunton River, 34 miles by rail S. of Boston. It contains a fine park, a court-house, city hall, a state lunatic asylum, and numerous foundries and cotton-mills, locomotive and copper works, shipyards, and manufactories of bricks, nails, jewellery, &c. Taunton was settled from Taunton in England in 1637. Its first minister was William Hooke, who afterwards married Cromwell's cousin, and became his chaplain. Pop. (1880) 21,213; (1890) 25,448.

Taunus Mountains. See Hesse-Nassau.

Taurida, a government of South Russia, with more than twice the area of Belgium (see Russia), bounded on the E., S., and SW. by the Sea of Azov and the Black Sea. The peninsula of the Crimea (q.v.) forms the southern portion of the government, and is connected with the northern portion by the Isthmus of Perekop (q.v.).

Taurus, Mount. See Asia Minor.

Tautog (*Tautoga onitis* or *americana*), a fish of the family to which the Wrasse (q.v.) belongs, found in the North American seas, and in great request for the table. It attains a weight of 12 or 14 lb. Its colour is black on the back and sides; the belly is whitish; each jaw has a double row of strong conical teeth; the face is covered with a scaleless integument. It is also called Black-fish and Oyster-fish.

Tautphœus, Baroness (1807–93), was the daughter of James Montgomery of Seaview, Co. Donegal, and married in 1838 an official at the Bavarian court. She is known as the authoress of a series of novels in English, mainly pictures of South German life, manners, and history, including *The Initials* (1850), *Cyrilla* (1853), *Quits* (1857), and *At Odds* (1863). Florence Montgomery (q.v.) is her niece.

Tavastehus, capital of a government in Finland, on Lake Vanajäjärvi, 50 miles N. of Helsingfors. Pop. 4098.

Tavern. See Inn, Licensing Laws.

Tavernier, Jean Baptiste, Baron d'Aubonne, a celebrated French traveller, was the son of an Antwerp Protestant engraver who had settled in Paris, and was born there in 1605. The conversation of the savants who frequented his father's shop made him a traveller at fifteen, and by the age of twenty-two he had seen France, England, the Low Countries, Germany, Switzerland, Poland, Hungary, and Italy. His *first journey* to the East lasted from about the beginning of 1631 to the summer of 1633, by Constantinople to Persia, thence by Aleppo and Malta to Italy. The *second journey* (1638–43) was from Marseilles to Alexandretta, across Syria to Ispahan, thence to Dacca, Agra, Surat, Goa, and Golconda; the *third* (1643–49), through Ispahan, much of Hindustan, Batavia, and Bantam, whence to Holland by the Cape and St Helena; and in the *fourth* (1651–55), *fifth* (1657–62), and *sixth* (1663–68) many districts of Persia and India were visited, the outward route being generally by way of Syria and the Arabian Desert, and the return one by Asia Minor. Tavernier invariably travelled as a dealer in precious stones and other valuable articles of small bulk, and the great profits he realised strongly impressed upon him the advantages of regular commerce between Europe and the East. He was well received by most of the eastern potentates—the Shah Abbás II. in 1657 gave him a robe of honour and made him his jeweller in ordinary, and the Great Mogul Aurungzebe kept him to see his annual festival in 1665. Louis XIV. gave him 'letters of nobility' in 1669, and next year he bought the barony of Aubonne near Geneva. In 1684 he started for Berlin to advise the Elector of Brandenburg in his projects for eastern trade. Next year he sold his estate, but it is quite unlikely that he was thrown into the Bastille after the revocation of the Edict of Nantes. He sent his nephew to India with a valuable cargo, but is supposed to have been defrauded by him. In 1687 we find the veteran traveller obtaining a passport in Switzerland, next year he appears to have been at Copenhagen, and in February 1689 he arrived in Russia, where he died at Moscow before the close of the year. His famous *Six Voyages* was published in 1676; the complementary *Recueil* in 1679. Tavernier traversed the plains of Troy, and passed the ruins of Persepolis without even a flutter of interest, and partly perhaps from this habit of mind his statements are accurate and truthful beyond the measure of travellers. But the chief value of his book lies in the fullness and accuracy with which are detailed the nature and state of oriental commerce, the chief markets and commercial routes, the precious stones found, and the various systems of coinage. Editions of the Travels are of 1810 (7 vols.) and 1882 (abridged).

See *Travels in India*, trans. by Dr V. Ball (2 vols. 1890), and Charles Joret, *Jean Baptiste Tavernier d'après des Documents Nouveaux* (1886).

Tavira, a seaport of Portugal, on the Sequa, 20 miles NE. of Faro. It has sulphur-baths, sardine and tunny fisheries, and a pop. of 11,459.

Tavistock, a pleasant market-town of Devon, 11 miles N. of Plymouth and 31 (by rail 40) SW. of Exeter, lies in a trough of the hills on the Tavy's left bank, with Dartmoor stretching away from it to the eastward. An old stannary town, till 1885 governed by a portreeve, it is the centre of what not many years ago was a great mining district; and it sent two members to parliament till 1867, then one till 1885. Two gateways, a porch, and the refectory are the chief remains of its once magnificent Benedictine abbey, founded in 961 by Ordgar, ealdorman of Devon, and father of the infamous Elfrida. It was rebuilt between 1285 and 1458, was the seat of a very early printing-press, and had a revenue of £902 at the dissolution in 1539, when it was conferred on the first Lord Russell, remaining still with his descendant, the Duke of Bedford. The parish church (1318) is a fine structure, with a west tower (106 feet) resting on arches. Tavistock has also a guildhall (1848), corn-market (1839), covered markets (1863), statues of the seventh Duke of Bedford by Stephens (1864) and Drake by Boehm (1883, a very fine one presented by the ninth Duke), and the Kelly College (1877), founded by Admiral B. M. Kelly. Drake and William Browne were natives, Pym and William Lord Russell members; and the Right Hon. W. H. Smith was educated at the grammar-school. Pop. (1851) 8086; (1891) 6252.

See works by A. J. Kempe (1830), Rachel Evans (1846), R. N. Worth (1888), and the Rev. D. P. Alford (1891).

Tavoy', the chief town of a district in Tenasserim, Burma, on the left bank of the Tavoy River, 30 miles from its mouth. Pop. 13,372.

Tax is a term wide enough to include all payments imposed by the government of a state on the persons and property within its jurisdiction. The revenue of a state is often derived in part from property held and managed by public authorities: the silver mines of Laurium belonged to the Athenian republic; and in the middle ages the king of England drew a large income from his crown-lands. Again, the revenue of a state is derived in part from payments for services performed—from the fees paid by suitors in the courts, the profits of the post-office, &c. If an adequate income could be obtained from these sources, it would not be necessary to levy taxes at all; but

no modern government has been able to subsist without taxation. In England the usage of six hundred years has established the rule that taxes are not to be levied unless with consent of parliament; and the House of Commons, as representing the general body of taxpayers, has taken the lead in voting money to the government, and in pointing out the ways and means by which the money is to be raised. It is the 'power of the purse' which makes the House of Commons politically supreme. The general principles to be applied by a taxing authority are tolerably plain and obvious. Taxes should be productive; it is not good policy to harass any interest for the sake of a small gain. They ought to be easily collected; it is not wise to allow the expenses of collection to eat up the tax. They ought to be just; that is to say, the sacrifice demanded from the individual citizen should be proportioned to his means. But abstract justice must be largely qualified by regard for usage; any sudden change in the incidence of taxation causes a disturbance of business, and so tends to diminish the wealth of the community. The chief object to be kept in view is the raising of the revenue required for public purposes, but taxation may be used for other ends. For example, taxes on intoxicating liquor and other luxuries are often defended on the ground that they discourage and restrict the sale of the articles taxed. Protectionists advocate high customs duties for the purpose of excluding foreign goods from competition with native industry. There are also many politicians who think that taxation may be used to correct social inequalities and to undo the effect of what seem to them to be unjust laws. The disciples of Mr Henry George would nationalise the land by taxing the owners at the rate of 20s. in the pound. Graduated taxation is recommended on the ground of abstract justice; it is suggested, for instance, that the income-tax and succession duty on an estate of £10,000 a year should be ten times as heavy as on an estate of £1000 a year. Schemes of this kind are attended by considerable practical difficulties; for high taxes lead to evasion and concealment, and rich men may even be tempted to remove themselves and their capital to another country.

Direct taxes (income-tax and succession duty for example) are paid by a person who cannot shift the burden of payment to another; indirect taxes (customs and excise for example) are paid by one person, while the burden falls on another. The duty on tea is paid by the importer, but he raises his price to cover the duty; it is therefore in fact paid by the consumer. Direct taxation is preferable, because it is levied on property, and can be adapted to the taxpayer's means. Indirect taxation is more easily raised; labouring people especially object to be called upon to pay money, while they are hardly conscious of the large contribution they make to the revenue in the shape of tea-duty and tobacco-duty. Where a government relies on customs and excise duties, it is good policy to refrain from taxing the necessaries of life and the raw materials of industry, and to put the duties on articles of luxury, such as beer and spirits, or tea and coffee. The amount of such duties must be fixed with care; for a high duty checks consumption, a low duty encourages it; for this reason a high duty is often less productive than a low one. Besides the taxes imposed by a national government (the Queen's taxes, as they are called in England) local authorities are usually permitted to levy rates and duties. In some countries octroi or import duties are paid on goods brought into a town; but the octroi is even more objectionable than a duty on foreign produce, inasmuch as it tends to discourage trade between different parts of the same country.

In taxation, as in other matters, the nations of modern Europe have followed closely the precedents of the Roman empire. The revenue of the emperor was raised by means of a tributum or land-tax, customs duties varying from one-fortieth to one-eighth of the value of goods imported, excise duties on certain trades, and a tax on legacies and successions. On the fall of the empire the prevalence of feudal ideas led to a complicated system of territorial exactions; the towns were able to purchase their freedom, but the peasantry were grievously burdened. The formation of strong national governments brought little relief to the people, except when, as in England, there was a representative body strong enough to limit the demands of royal power. France under Louis XIV. may be quoted as a typical example of the evils caused by unjust taxation, unjust exemption of privileged classes, and a bad system of collection; the taxes were farmed out to private speculators, and the necessaries of life were rendered outrageously dear; the salt-tax especially is always named among the worst abuses of the old régime. The economists of the 18th century recalled the minds of statesmen to true principles, while practical reformers like Turgot showed them 'how to pluck the goose without making it cry.' Since the revolt of the English colonies in America (a revolt caused by an impolitic attempt to tax self-governing communities without their consent), and the abolition of feudalism in France at the Revolution, the revenue laws of civilised countries have been greatly altered and improved. In the United Kingdom customs duties are now levied on a few articles, none of which can be described as necessaries; excise duties, once highly unpopular, are levied only on intoxicating liquor, and on some more or less privileged trades and professions; the income and property tax, remodelled by Sir R. Peel in 1842, is fairer and more searching than the old land-tax; the probate and succession duties help to relieve trade and industry at the expense of realised property. Complaints of the incidence of taxation are still very common, and no political question is more keenly discussed. There is much difference of opinion as to land, some contending that land-values should be more heavily taxed, others again maintaining that the land is unfairly burdened, and that personal property should be made to contribute to local rates.

For particulars of the revenue of modern governments, see the *Statesman's Yearbook* and the works there referred to; also the articles in this work on the various countries (Great Britain, United States, &c.). Adam Smith and Ricardo are still the highest English authorities on the principles of taxation. See also A. J. Wilson's *Resources of Modern Countries* (1878); Goschen on *Local Taxation* (1873); S. Dowell, *Taxation and Taxes in England from the Earliest Times* (2d ed. 4 vols. 1888); works on the law of taxation in the United States by Burroughs (1876) and Cooley (1877); Boutwell, *Taxation System of United States* (1863); R. T. Ely, *Taxation in America* (1888); J. Dean Goss, *The History of Tariff Administration in the United States* (1891); French works by Parieu (1866) and Rousset (1883); German works by Schäffle (1880), Roscher (1886), Meyer (1884), Mangoldt (1886); also works noted at POLITICAL ECONOMY, and the articles on Aids, Benevolence, Budget, Corn Laws, Customs Duties, Excise, Free Trade, Income-tax, Land Laws, Legacy, National Debt, Poor-laws, Protection, Smuggling, Tonnage and Poundage, &c.

Taxation of Costs. See COSTS.

Taxidermy, the name given to the art of putting up natural history specimens in the dried state. It includes the skinning and stuffing of fishes, reptiles, amphibians, birds, and mammals; also the preserving, drying, and setting up of insects and other invertebrata. But it does not

properly comprise the making of wet zoological preparations which are to be preserved in spirits; nor, strictly speaking, does it include the articulating of skeletons, although this is usually treated of in books on taxidermy.

For the skinning of animals a few tools, such as scalpels, scissors, and forceps, are required. Incisions must be made in certain directions. Care has to be taken not to stretch the skin in detaching it from the body, and it is necessary to avoid soiling the plumage of birds or the hair and fur of mammals with blood or grease. The skull and certain wing and leg bones are left in their place to preserve as perfectly as possible the form of these parts in case of the skin being afterwards mounted. Considerable difference of opinion has of late years arisen as to the best treatment for preserving or, as it is sometimes called, poisoning skins. Arsenical soap is still largely used. It commonly consists of arsenious acid 1 oz., white soap 1 oz., carbonate of potash 1 drachm, distilled water 6 drachms, and camphor 2 drachms. To preserve bird skins some prefer powdered white arsenic (arsenious acid) either alone or mixed with powdered alum; and nothing else is much used in the United States. But sometimes powdered oak-bark and a little camphor are added, the proportions being arsenic 1 part, alum 1 part, bark 2 parts, camphor ½ part. These powders should be applied to the inner surface of the skin when it is moist. A non-poisonous preservative soap of the following composition has been recommended: chalk 2½ lb., soft soap 1 lb., chloride of lime 2 oz., tincture of musk 1 oz. But as it is difficult to prevent a little free chlorine escaping from chloride of lime, there must be some risk of corroding or rotting skins by the use of this mixture. These dry powders should be well rubbed, and the soapy mixtures carefully brushed, into the wet surface of skins. An alcoholic solution of corrosive sublimate is a good preservative for skins, but it is very poisonous. For cleaning feathers, and especially those that are light coloured, powdered plaster of Paris is very effective. Wherever bird skins or the fur-covered skins of mammals are kept camphor or naphthaline should be present. The latter is more obnoxious to destructive moths than the former, as it has a powerful and peculiar odour. Benzene is also very useful. Butterflies, moths, and other insects require to be kept in drawers or boxes of a peculiar construction to prevent the escape of the vapour of camphor or other preservative.

It would occupy too much of our space to describe in detail the process of stuffing or mounting an animal. Before the taxidermist can stuff or mount well he requires some training in anatomy and modelling, and a knowledge of the external forms of animals, as well as some acquaintance with their habits. He cannot be a master of the art unless he has the artistic faculty in a high degree. With rare exceptions, the remuneration hitherto obtained for stuffing animals has not been sufficient to secure the services of persons trained to produce high-class work. This explains why so many specimens in museums of natural history are so faulty and unattractive. That birds, mammals, and other animals can be made beautiful, instructive, and even of real service to science in the mounted state is, however, clearly seen in some examples of the handiwork of Hancock of Newcastle, Ward of London, Verreaux of Paris, and others. But specimens of the taxidermist's art far in advance of anything ever attempted before have within the last few years been prepared for the natural history museum at South Kensington. Here to each species of British birds a glass case is (or will be) devoted, in which are placed the male, female, and eggs, or young. In addition, the nesting-place of the bird, whether this be a sylvan, pastoral, sandy, or rocky spot, is carefully modelled to show its habitat. All this is represented with so much truth and fidelity to nature, and is in every way so interesting and attractive, as to cause regret that only the funds at the disposal of a great national institution can cope with so costly an undertaking.

See *Methods of the Art of Taxidermy*, by Oliver Davie (1892); *Practical Taxidermy*, by Montagu Browne (1884); *Field Ornithology*, by Coues (1890); and *Taxidermy*, by W. T. Hornaday (1891).

Tay, a river of Scotland, draining nearly the whole of Perthshire, and pouring into the German Ocean a greater bulk of water than any other British river, rises on Benloy, on the Argyllshire border, at an altitude of 2980 feet. Thence it winds 118 miles east-north-eastward, south-south-eastward, and eastward—for the last 25 miles as a tidal estuary, ½ mile to 3¼ miles broad, which separates Perth and Forfar shires from Fife. In the first 25 miles of its course it bears the names of Fillan and Dochart; it then traverses Loch Tay, and it afterwards passes Aberfeldy, Dunkeld, Stanley, Perth, Dundee, and Broughty-Ferry. Its principal affluents are the Tummel (58 miles long, and sometimes regarded as a northern head-stream), Isla, Almond, and Earn. The Tay, as it is the most beautiful of Scottish rivers, so it is unrivalled for its salmon-fisheries, whose rental in good years exceeds £20,000. Vessels of 100 tons can ascend as high as Perth, but even to Dundee the navigation of the firth is much impeded by shifting sandbanks.

Loch Tay lies 355 feet above sea-level, extends 14½ miles north-eastward from Killin to Kenmore, is ½ to 1½ mile broad, 15 to 100 fathoms deep, and covers 6550 acres. It is a magnificent Highland lake, flanked on the north-west by Ben Lawers (4004 feet), and containing near its foot a wooded islet, with a fragment of an Augustinian priory, founded in 1122 by Alexander I., who here buried his queen, Sibylla. In September 1842 Queen Victoria was rowed up Loch Tay, on which a steamer was first launched in 1883, and a railway to which, at Killin, was opened in 1886.

See the articles Pisciculture, Dundee (for the Tay Bridge), Rannoch, Earn, Perthshire, &c., and works there cited, with J. Geddie's finely illustrated monograph on the Tay (1892).

Tayler, John James, an eminent Unitarian divine, was born at Newington Butts, August 15, 1797, son of a minister in London, next at Nottingham. He studied at Manchester New College (which was located at York 1803–40), at Glasgow University, and again at York, was ordained to Mosely Street Chapel at Manchester in 1821, and became professor of Ecclesiastical History in 1840 on the return of the college to Manchester. He spent a year (1834–35) in study at Göttingen and Bonn, removed with his college to London in 1853, becoming principal as well as professor, was joint-minister with James Martineau of Little Portland Street Chapel (1858–60), and died 28th May 1869. He wrote much for the *Prospective Review*, which passed in 1855 into the *National Review*, and made way in 1864 for the *Theological Review*, a list of as many as 102 books, discourses, and articles being appended to the collection of his *Letters*, edited by J. Hamilton Thom (2 vols. 1872).

Of the books the chief were *A Retrospect of the Religious Life of England* (1845), which Martineau styles 'the most charming of ecclesiastical histories;' *Christian Aspects of Faith and Duty* (1851); and *An Attempt to ascertain the Character of the Fourth Gospel* (1867).

Taylor, Bayard, an American author and traveller, was born, of Quaker and German ancestry, at Kennett Square, Chester county, Pennsylvania, January 11, 1825. Having received a

common school education, he was apprenticed at seventeen in a printing-office, in 1844 published *Ximena*, a volume of poems, and started on a pedestrian tour of Europe, and in 1846 published *Views Afoot, or Europe seen with Knapsack and Staff*. After his return he edited a country newspaper, then went to New York, and obtained a post on the *Tribune*. As its correspondent he made extensive travels in California and Mexico, recorded in *El Dorado* (1850), and up the Nile, and in Asia Minor, Syria, across Asia to India, China, and Japan—recorded in his *Journey to Central Africa and Land of the Saracen* (1854), and *Visit to India, China, and Japan* (1855). Later explorations are recorded in *Northern Travel* (1858), and *Travels in Greece and Russia* (1859). In 1862–63 he was secretary of legation at St Petersburg; in 1874 he visited Iceland. In May 1878 he became ambassador at Berlin, where he died 19th December of the same year. His principal reputation, however, was as a poet. His works include *Rhymes of Travel* (1848); *Book of Romances, Lyrics, and Songs* (1851); *Poems of the Orient* (1854); *Poems of Home and Travel* (1855); *The Poet's Journal* (1862); *Poems* (1865); *The Masque of the Gods* (1872); *Lars* (1873); *The Prophet, a Tragedy* (1874); *Home Pastorals* (1875); *The National Ode* which he was chosen to deliver at the Centennial Exhibition (1876); *Prince Deukalion*, a drama (1878); and an admirable translation of *Faust* (1870–71). He also wrote several novels, the best *Hannah Thurston* (1863) and *The Story of Kennett* (1866). See his *Life and Letters* (2 vols. 1884).

Taylor, Brook, mathematician, was born of good family at Edmonton in Middlesex, August 18, 1685, and studied at St John's College, Cambridge. In 1715 he published his *Methodus Incrementorum Directa et Inversa*, the foundation of the Calculus of Finite Differences. Herein also is the formula which, as 'Taylor's theorem,' will keep his name from ever being forgotten. In 1716 he visited Paris and was warmly received by the French savants. From 1714 till 1718 he acted as secretary to the Royal Society. His last years were given to speculations in philosophy and religion, and were darkened by the early deaths of two successive wives. He himself died December 29, 1731. Other works were a *Treatise on Linear Perspective* (improved ed. 1719) and the posthumous *Contemplatio Philosophica* (edited by his grandson, Sir W. Young, with Life, 1793). Several short papers may be found in the *Phil. Trans.* (1713–23).

Taylor, Sir Henry, poet, was born, the son of a gentleman-farmer of unusual culture, at Bishop-Middleham in Durham, October 18, 1800. At fourteen he went to sea as midshipman, but was happy to obtain his discharge after nine miserable months, and two years later was given a clerkship in the Storekeeper-general's Department. After four years' service, including a few months in Barbadoes, he lost his post through internal official rearrangements, and returned to his father's house, Witton Hall, to spend two years of uninterrupted quiet and study. He began to write for the *Quarterly*, and in 1823 settled in London, having been appointed through the influence of Dr (after Sir Henry) Holland to a clerkship in the Colonial Office. Here he laboured for forty-eight years under as many as twenty-six secretaries of state, retiring only in 1872. He declined in 1847 the post of permanent under-secretary in succession to Sir James Stephen, and in 1869 was made K.C.M.G., partly for his public services, partly for his literary work—the latter also acknowledged by the D.C.L. degree at Oxford in 1862. His last days were spent at Bournemouth, and here, March 27, 1886, he ended a long and happy life, the happiness of which was in great measure due first to his admirable step-mother, later to his equally admirable wife, Alice Spring Rice, a daughter of Lord Monteagle. Taylor wrote four tragedies in the Shakespearian manner: *Isaac Comnenus* (1827), *Philip van Artevelde* (1834)—an immediate success, *Edwin the Fair* (1842), and *St Clement's Eve* (1862); and one romantic comedy, *The Virgin Widow*, afterwards entitled *A Sicilian Summer*. In 1845 he published a small volume of lyrical poetry, and in 1847 *The Eve of the Conquest and other Poems*. His work in prose embraced *The Statesman* (1836), a collection of Baconian discourses on official life and the methods of managing men, for which, as he himself says, 'Pragmatic Precepts' would have been a better title; *Notes from Life* (1847)—one of its essays, *The Life Poetic*, mainly a eulogy of Southey; and *Notes from Books* (1849), half made up of two articles on Wordsworth. Last came his interesting *Autobiography* (2 vols. 1885), admirably written, full of genial observation, and not marred at all by the pardonable egotism of age and merit. It contains a fine series of pen-portraits of such contemporaries as Wordsworth, Southey, Scott, Sydney Smith, Mill, Sir James Stephen, Spedding, Carlyle, Tennyson, and Aubrey de Vere. It was supplemented by his only less delightful *Correspondence* (1888), a selection of 202 letters, edited by Professor Dowden, including also letters to Taylor, from Wordsworth, Southey, Stephen, Mrs Norton, Macaulay, Spedding, Tennyson, Aubrey de Vere, Gladstone, Dr John Brown, and Swinburne. A uniform collected edition of his works had appeared in 5 vols. in 1878.

Taylor, Isaac, writer of many books on religious and philosophical subjects, was born at Lavenham in Suffolk in 1787. His father, Isaac Taylor the first (1759–1829), was originally a London engraver, but in 1796 became Independent minister at Colchester, in 1811 at Ongar in Essex, and published a score of volumes. Charles Taylor (1756–1821), editor of Calmet's *Bible Dictionary*, was an uncle, and two sisters were Jane Taylor (1783–1824), author of the *Contributions of Q.Q.*, and Ann Taylor (Mrs Gilbert of Nottingham, 1782–1866; *Autobiography*, 1871), joint-authors of the famous *Hymns for Infant Minds* and *Original Poems*. After a course of study he settled down to a busy literary life at Ongar, where he died, June 28, 1865. As early as 1818 a writer in the *Eclectic Review*, he lived to contribute to *Good Words*—a period of over forty years. In 1862 he was granted a Civil List pension of £100. Of his many books the most important were the *Natural History of Enthusiasm* (1829), *The Natural History of Fanaticism* (1833), *Spiritual Despotism* (1835), *Physical Theory of Another Life* (1836), and *Ultimate Civilisation* (1860).—His eldest son, Isaac Taylor, was born at Stanford Rivers, May 2, 1829, had his education at Trinity College, Cambridge, took orders, and after acting as curate in London and elsewhere, and as vicar of St Mathias, Bethnal Green (1865–69), and Holy Trinity, Twickenham (1869–75), was presented to the rectory of Settrington in Yorkshire in 1875, and collated to a canonry of York in 1885. His *Words and Places* (1864) made him favourably known as a philologist, whilst his great work, *The Alphabet, an Account of the Origin and Development of Letters* (2 vols. 1883; new ed. 1899), brought him a wide reputation. Other publications are *The Family Pen; Memorials of the Taylor Family of Ongar* (2 vols. 1867); *Etruscan Researches* (1874); *Greeks and Goths, a Study on the Runes* (1879); *The Origin of the Aryans* (1890); and *Names and their Histories* (1896). Besides these he has contributed much to the learned journals, and not a few articles on philological questions to the present work.

Taylor, JEREMY, the glory of the English pulpit, was the third son of a Cambridge barber of Gloucestershire family, a descendant of Dr Rowland Taylor, the Marian martyr, and was born in that town, and baptised on August 15, 1613. At thirteen he entered Cains College as a sizar, graduated B.A. in 1630-31, and, according to his friend and successor Bishop Rust, was thereafter chosen fellow of his college. At any rate he became M.A. in 1633, about the same time being admitted to holy orders, and soon after he attracted the notice of Laud, who had a regard for learning, if none for liberty, and was preferred through his influence to a fellowship at All Souls in Oxford (1636). He became also chaplain to the archbishop, and in 1638 was presented by Bishop Juxon to the rectory of Uppingham. About this time Wood tells us he was suspected by watchful zealots of a concealed attachment to the Romish communion, whether from his ascetic notions of piety, his veneration for antiquity and love for the picturesque aspects of religion, the favour of Laud, or his friendship with the learned and pious Franciscan friar, Francis a Sancta Clara [Christopher Davenport]. Taylor married Phœbe Landisdale, or Langsdale, in 1639; his second wife, Joanna Bridges, was believed by Bishop Heber, chiefly on the authority of the MS. of Mr Jones, a descendant of Taylor's, to have been an illegitimate daughter of Charles I. when Prince of Wales. His *Episcopacy asserted against the Acephali and Aërians New and Old* (1642) scarcely gave promise of his future powers, but gained him the empty honour of a D.D. degree. During the struggle Taylor is supposed to have accompanied the royal army as a chaplain, but about the close of 1643 we find him living with his mother-in-law and children, and embarrassed by poverty. Heber thinks his first wife was already dead, and that soon after this time he married his second, and retired to her property at Mandinam in Caermarthenshire. At any rate, after the downfall of the cause he found a shelter in Wales, and for some time he joined in keeping a school at Newton Hall in the parish of Llanfihangel. Here he found a kind patron in Richard Vaughan, Earl of Carbery, then living at the family seat of Golden Grove, immortalised in the title of Taylor's still popular manual of devotion (1655). His second countess was Alice, daughter of John Egerton, first Earl of Bridgewater, and the original of the 'lady' in Milton's *Comus*. During the last thirteen years (1647-60) of Taylor's enforced seclusion appeared all his great works, some of these the most enduring monuments of sacred eloquence in the English language. The first was *The Liberty of Prophesying* (1647), a noble and comprehensive plea for toleration and freedom of opinion, far above the ideas of its age, and even of its author in his turn of triumph. Here he takes the Apostles' Creed as the minimum standard of Christian communion, the only necessary terms of such being those dogmas that are capable of being propounded *infallibly;* that is, from Scripture, in the due exercise of Reason, all such errors as may arise being necessarily venial, when not wilful. 'Heresy is not an error of the understanding, but an error of the will,' to which proposition Coleridge aptly adds its converse, 'faith is not an accuracy of logic, but a rectitude of heart.' 'Those creeds are best which keep the very words of Scripture; and that faith is best which hath greatest simplicity; and it is better in all cases humbly to submit, than curiously to inquire and pry into the mystery under the cloud, and to hazard our faith by improving our knowledge.' He next passes in review the alleged special sources of authority in religious opinion: Scripture, Tradition, Ecclesiastical Councils, the Pope, and the Fathers, finding all save Scripture, interpreted by an enlightened reason, insufficient and contradictory. With regard to civil government he lays down broadly the principle that it is not concerned with opinions, however false or absurd, unless these tend directly to the prejudice of government as such, thus demanding the widest toleration for honest opinion ranging from Anabaptism to Popery. The second edition (1659) closes with the celebrated story of Abraham and the idolatrous traveller.

In 1650 followed the *Life of Christ, or the Great Exemplar*—an arrangement of the facts in historical order, interspersed with prayers and discourses on topics suggested by the narrative. That same year appeared *The Rule and Exercises of Holy Living*, followed in 1651 by its counterpart, *The Rule and Exercises of Holy Dying*, together forming to generation after generation the choicest classic of English devotion. The twenty-seven *Sermons* for the summer half-year were published in 1651; the twenty-five for the winter half-year in 1653. These, with the discourses in the *Life of Christ* and many passages in the *Holy Living* and *Dying*, contain the richest examples of their author's characteristically gorgeous eloquence. The polemical and practical treatises are more subdued in style, though still figurative and allusive far beyond the measure even of his contemporaries; but here he gave full reins to an imaginativeness unmatched alike in range of illustration and in opulence of language. The solemn music of his words, the rich beauty of the imagery in his incidental metaphors, the tenderness, passion, colour, and force, if not precision, of phrase combine to place these writings by themselves on a level scarce attained by all the Asiatic eloquence of Chrysostom.

The more formal treatises were *An Apology for Authorised and Set Forms of Liturgy against the Pretence of the Holy Spirit* (1646); *Clerus Domini, or a Discourse of the Divine Institution, Necessity, Sacredness, and Separation of the Office Ministerial* (1651); *The Real Presence and Spiritual of Christ in the Blessed Sacrament proved against the Doctrine of Transubstantiation* (1654); *The Unum Necessarium, or the Doctrine and Practice of Repentance* (1655), a treatise with a decided taint of Pelagianism, where the theologian had ventured beyond his depth, and which involved him in a cloud of controversy; *The Worthy Communicant* (1660); *Defence and Introduction to the Rite of Confirmation* (1663); *The Dissuasive from Popery* (1664); and the famous *Ductor Dubitantium, or the Rule of Conscience in all her General Measures* (1660), the most learned and subtle of all his works, which he himself counted on as the foundation of his fame. Intended as a complete handbook of Christian casuistry and ethics, it labours first to establish a system of morality on the basis of the will of God revealed to us through Conscience, distinguishing with greater subtlety than security the right or sure conscience, the conscience confident in error, the probable or thinking, the doubtful, and the scrupulous conscience. Under the 'probable' head he gives a magnificent sketch of the different probabilities on which a faith in Christianity is founded. The second book discusses the obligations of conscience in relation to the law of nature and the law of Christ, closing with a splendid peroration on the measures and motives of a Christian's duty. In the third book he passes to human positive law alike of church and state, and in the fourth—the best part of the whole—he closes with a discussion of the nature and causes of good and evil, and the efficient and final causes of human actions. But Taylor is much more a rhetorician than a thinker or even a theologian, and his imagination too often carries him at a leap from an illustration to an argument, from

an analogy to a conclusion. Distinctions without a difference, inconsistencies, sophistries, and prolixity are foibles that too easily beset his argument, and go far to mar the effect of vast erudition, subtlety of thought, and dazzling eloquence. Besides the real bases of the controversy have shifted far from the 17th-century landmarks, and much of his subtlest argument is to modern men a mere beating of the air. Nor is he altogether free from the special sin of casuistry in its narrowest sense—he maintains that private evil may be done for the public good, that in controversy it is allowable to employ arguments and authorities we know to be invalid, and he is able to justify on moral grounds the fraudulent Israelitish borrowing from the Egyptians. He is besides much too slavish in his respect for authority and tradition, but, as Coleridge says well, Jeremy Taylor 'would have been too great for man had he not occasionally fallen below himself.'

During the troubles Taylor was thrice imprisoned, once for the preface to the *Golden Grove;* the last time in the Tower for an 'idolatrous' print of Christ in the attitude of prayer in his *Collection of Offices* (1658). He occasionally visited London, where he numbered among his friends John Evelyn, to whom he wrote many admirable letters still extant, as well as Boyle, George Berkeley, afterwards first Earl of Berkeley, and Wilkins. In 1658 he was given by the Earl of Conway a lectureship at Lisburn in Ireland, and at the Restoration he was made bishop of Down and Connor, to which was added next year the small adjacent see of Dromore. By Ormonde's recommendation he was elected vice-chancellor of the university of Dublin, and in February 1661 he was admitted a member of the Irish privy-council. There were many stubborn Presbyterians in his diocese who mocked at his authority, and tormented his gentle spirit, but we need not believe that the plot to take his life existed anywhere else than in his active imagination. In his first visitation he ejected thirty-six ministers from their churches, but neither severity nor gentleness could prevail to force a form of religion upon an unwilling people. His last years were clouded also by domestic sorrows. His eldest son, an officer in the army, was killed in a duel; the second passed from Trinity College to become the favourite companion and secretary to Buckingham, and died a few days before his father. The three daughters of his second wife alone survived him. He died at Lisburn after a ten days' fever, 13th August 1667, and was buried in the choir of the cathedral at Dromore, largely rebuilt by his own munificence.

Jeremy Taylor's beauty of person corresponded to the beauty of his character and the large charity of his temper. Good portraits are abundant, several he himself gave as frontispieces to his writings; one of the best hangs in All Souls College, Oxford. Bishop Heber endorses Parr's description of Hooker as the object of our reverence, Barrow of our admiration, but Jeremy Taylor of our love. He was above all things a preacher, and that especially of personal holiness. The thread of ideas is ever clear and simple underneath all his exuberant fullness and the stately march of his sentences, and though it is difficult to conceive of a congregation capable of following his argument and illustration in their full detail, all the haste and indistinctness of argument, the quaint, pedantic, and even grotesque irrelevances of illustration are fused together into harmony in the orator's glowing earnestness and fire. No poet ever excelled Jeremy Taylor in exquisite feeling for the sights and sounds of nature; he has no rival in lofty and impassioned prose save Milton alone—'Most eloquent of divines,' says Coleridge, 'had I said of men, Cicero would forgive me, and Demosthenes nod assent.'

The first collected edition of his works was that of Bishop Heber, with an excellent Life (15 vols. 1820–22); a revised edition by the Rev. C. P. Eden (10 vols. 1847–54). See Coleridge's *Literary Remains*, vol. iii. (1838); Tulloch's *Rational Theology in England in the Seventeenth Century*, vol. i. (1872); Archdeacon Farrar in *Masters in Eng. Theology* (1877); and Bishop Barry in *Classic Preachers of the Eng. Church*, series ii. (1878); also an admirable article in the *Quarterly Review* for July 1871.

Taylor, John, the 'Water-poet,' as he styled himself, was born at Gloucester in 1580, and became a waterman on the Thames, but was pressed into the naval service and served at the siege of Cadiz. He collected for many years for the lieutenant of the Tower his perquisite of wine from all ships which brought wine up the Thames. When the rebellion broke out in 1642 Taylor left London for Oxford, where he kept a public-house, which he afterwards gave up for another in London, and here he hawked the doggerel which he wrote. He performed some fantastic feats of rowing, but the chief event of his life was his journey on foot from London to Edinburgh (14th July—13th August 1618). Ben Jonson thought the Water-poet's intention was to burlesque his own journey, yet when he met him at Leith he gave him a piece of gold to drink his health in England. Taylor described his journey in his *Penniless Pilgrimage* (1618); other books of the same kind were his *Travels in Germanie* (1617) and *The Praise of Hempseed*, a story of a voyage from London to Queenborough in Kent in a brown paper boat (1618). He died in 1654. Taylor's works were published under the title of *All the Workes of John Taylor the Water-poet, being sixty and three in number* (1630, folio). His poems are not destitute of natural humour, abounding with the low, jingling wit which prevailed in the reign of James I., and which too often bordered upon bombast and nonsense. Allibone's *Dictionary* contains a list of 138 articles written by the Water-poet. The best reprint of his works is a complete edition issued by the Spenser Society (1868–78).

Taylor, Nathaniel William, preacher and theologian, was born at New Milford, Connecticut, 23d June 1786, studied at Yale, became pastor of a Congregational church at New Haven in 1812, and in 1822 became professor of Theology in Yale College, where he taught until his death, 10th March 1858. In numerous sermons, lectures, and essays he maintained what from his pastoral charge became known as the 'New Haven theology,' long assailed as heretical. This system, a softening of the traditional Calvinism of New England, maintained the doctrine of natural ability, and denied total depravity; sin is a voluntary action of the sinner; but there is, derived from Adam, a *bias* or *tendency* to sin, which is not itself sinful. His works were edited in 5 vols. by his son-in-law, Dr Noah Porter (1858–59).

Taylor, Philip Meadows, Indian administrator and author, was born at Liverpool 25th September 1808, held a mercantile post in Calcutta, but obtained a commission in the army of the Nizam of Hyderabad, whom he served from 1826 as administrator of various large territories, one of them the tributary state of Sherapur. In this capacity he showed marvellous insight, tact, and kindliness, establishing order and justice in place of mere barbarous tyranny, and maintained peace during the mutiny of 1857. The British government gave him charge of some of the ceded districts; in 1866 he retired colonel and C.S.I.; and he died at Mentone, 13th May 1876. He left vivid pictures of Indian history, life, and manners in his romances,

Confessions of a Thug (1839; new ed. 1858); *Tippoo Sultaun* (1840); *Tara* (the story of Sivaji, 1863); *Ralph Darnell* (1865); *Seeta* (1873); and *A Noble Queen* (1878). See his *Story of my Life*, edited by his daughter (1877; new ed. 1881).

Taylor, Rowland, Marian martyr, was a native of Rothbury in Northumberland, and studied at Cambridge, taking his LL.B. in 1530 and LL.D. in 1534. Cranmer, to whom he was domestic chaplain, gave him the rectory of Hadleigh in Suffolk (1544), and he subsequently became archdeacon of Exeter (1551) and a canon of Rochester. Under Mary he was imprisoned as a heretic for more than a twelvemonth in the King's Bench, and on 8th February 1555 was burned near Hadleigh. See Cooper's *Athenæ Cantabrigienses* (1858).

Taylor, Thomas, 'the Platonist,' was born in London, 15th May 1758, went three years to St Paul's School, next studied mathematics and classics under private teachers, but, betwixt an imprudent marriage and the pinch of poverty, found it impossible to realise his dream of completing his studies at Aberdeen with a view to the ministry, and entered Lubbock's bank as a clerk. But he still found six hours in every day for study, and at length left his desk to teach private pupils and fill the office of assistant-secretary to the Society for the Encouragement of Arts, &c. During his last forty years he lived in a small house at Walworth, immersed in Plato and the Platonist philosophers, and partly supported by a gift of £100 a year from Mr Meredith, a retired tradesman with ideas, and here he died, November 1, 1835. His fifty works include translations of the Hymns of Orpheus, and parts of the works of Plotinus, Proclus, Pausanias, Apuleius, Maximus Tyrius, the Greek mathematicians, Iamblichus, Hierocles, Porphyry, &c., besides complete translations of Plato (nine, however, of the Dialogues by Floyer Sydenham, 5 vols. 1804) and Aristotle (11 vols. 1806–12). Mr W. E. A. Axon in a biographical and bibliographical sketch (privately printed, 1890) gives a list of forty-eight books, but does not include *The Spirit of All Religions* (Amst. 1790), which expresses his strange polytheistic creed.

Taylor, Tom, journalist and playwright, was born in 1817 at Sunderland, and passed from the Grange School there in 1831 to Glasgow University, and thence in 1837 to Trinity College, Cambridge, where he graduated as third classic in 1840, and was elected to a fellowship. Professor for two years of English language and literature at University College, London, he was called to the bar of the Inner Temple in 1845, for a short time travelled the northern circuit, and from 1850 to 1872 was first assistant-secretary and secretary to the Board of Health, and then secretary to the Local Government Act Office. From 1846 onwards he wrote or adapted upwards of a hundred pieces for the stage, of which may be mentioned *Our American Cousin*, *Still Waters Run Deep*, *The Ticket of Leave Man*, and *Twixt Axe and Crown*. He also edited the autobiographies of Haydon and Leslie, completed the latter's *Life and Times of Reynolds*, translated *Ballads and Songs of Brittany* (1865), and in 1874 succeeded Shirley Brooks as editor of *Punch*. He died at Wandsworth, 12th July 1880.

Taylor, William, 'of Norwich,' was born there in 1765, the only son of a rich Unitarian merchant, and was educated at Palgrave by Mrs Barbauld's husband. At fourteen he entered his father's counting-house, but next year was sent on the first of two visits to the Continent, where he mastered French, Italian, and, more especially, German. The French Revolution at once indoctrinated him with democratic ideas and began the ruin of his father's business, which by 1811 was completed by American 'repudiation' and a stock-broker's bankruptcy; Taylor had meanwhile turned wholly from commerce to literature. His is the credit of introducing to English readers the poetry and drama of Germany, mainly through criticisms and translations contributed to periodicals, and collected in his *Historic Survey of German Poetry* (3 vols. 1828–30). Other works by him were *English Synonyms Discriminated* (1813) and a *Life of F. Sayers, M.D.* (1823). He died at Norwich in March 1836. George Borrow, his pupil in German, has sketched in *Lavengro* his philosophy, scepticism, and inveterate tobacco-smoking; and his correspondence with Southey, Scott, Mackintosh, Godwin, &c. is given in J. W. Robberds' memoir of his *Life and Works* (2 vols. 1843).

Taylor, Zachary, a distinguished general and twelfth president of the United States, was born in Orange County, Virginia, 24th September 1784. His father had been a colonel in the war of independence, and removed to Kentucky in 1785, settling near Louisville. Here Zachary lived on a plantation until 1808, when he entered the army as lieutenant. In 1812 as captain he commanded Fort Harrison on the Wabash, and in September with only fifty men, two-thirds of whom were on the sick-list, successfully defended that post against a large body of Indians. After further service on the north-western frontier Taylor became major, but at the close of the war being reduced to a captaincy he resigned his commission. He was soon reinstated and again employed against the Indians, and in 1832 fought with Black Hawk, the noted chief of Illinois. In 1836 Taylor, now colonel, was ordered to Florida, where previous commanders had suffered in reputation from their vain attempts to subdue the troublesome Seminoles. Taylor had the good fortune to defeat the savages at Okeechobee Swamp on Christmas Day 1837, and thus won the brevet of brigadier-general. In 1840, being placed in command of the army in the south-west, he removed his family to a plantation at Baton Rouge, Louisiana.

When Texas was annexed in 1845 its western boundary was not defined, and Mexico still claimed the uninhabited district between the Rio Grande and the Nueces. Taylor, being ordered to defend Texas from invasion, sailed from New Orleans to Corpus Christi, where he gathered a force of 4000 regulars. Though well aware that President Polk wished him to occupy the disputed district, he would not cross the Nueces until express orders came in March 1846. He then marched to the Rio Grande and erected Fort Brown opposite the Mexican town of Matamoros. The Mexicans ordered him to retire, and upon his refusal crossed the Rio Grande to drive him out. Their action enabled President Polk to declare that the United States had been invaded, and to call for volunteers to repel the foe. But the battles of Palo Alto and Resaca de la Palma on the 8th and 9th of May drove the Mexicans back, and Taylor following seized Matamoros. The volunteers did not come to his aid until September, when he marched to Monterey, and after a severe struggle captured it on the 24th. After seven weeks' vain waiting for more troops the march was resumed. The city of Victoria was occupied on December 29, but the line of communication was found too long for the meagre force, while Polk's Democratic administration, fearing the rising fame of Taylor, who was a Whig, crippled him by withholding reinforcements.

Taylor was already falling back to Monterey when his regulars were taken from him to form part of the new expedition under General Scott. Santa Anna, the ablest Mexican general, learning

of Taylor's weakened condition, believed that with his 21,000 veterans he could crush the 5000 American volunteers. After a march of hundreds of miles, he overtook Taylor near the mountain-pass of Buena Vista. Availing himself of its natural advantages, Taylor on the 22d of February 1847 completely repulsed the Mexicans with a loss thrice as great as his own. In the following November General Taylor returned home and was received with enthusiastic expressions of popular favour. In June 1848 the convention of the Whig party, passing by its great political leaders, selected him as the candidate for the presidency. A few Free Soilers refused to support him as being a slaveholder, but his character, indicated by the sobriquet of 'Rough and Ready,' endeared him to the masses. He was triumphantly elected in November and inaugurated in the following March. The fierce struggle over the extension of slavery to the newly-acquired territory had begun. The congress was Democratic and opposed the admission of California as a free state, while the president favoured it. To avert the threatened danger to the Union Henry Clay introduced his famous compromise, which called forth a stormy discussion. Taylor remained firm and impartial, though his son-in-law Jefferson Davis was the leader of the extreme pro-slavery faction. Before a decision was reached in congress President Taylor died suddenly of bilious fever, 9th July 1850.

General Taylor was of medium height, stout and swarthy. He was plain in manners and speech, and careless in dress; he rarely wore uniform, and often sat sideways on his horse. His ability as a commander is shown by his unvarying success in battle, and is attested by General Grant, who served under him as lieutenant. Though Taylor had taken little part in political strife, he carried off the prize which great party leaders failed to win. As president he showed himself a true promoter of his country's welfare. There are Lives by Frost (1848), Fry and Conrad (1848), and O. O. Howard (1892).

Tayport, a watering-place and police-burgh of Fife, on the south side of the entrance of the Firth of Tay, opposite Broughty-Ferry (q.v.), and 3½ miles E. by S. of Dundee. Pop. (1891) 2829.

Tchad, LAKE. See TSAD.

Tchuktchis. See SIBERIA.

Tea (*Camellia theifera*, Griff.) is a plant of the genus Camellia (q.v.), natural order Ternstrœmiaceæ, of which there are two well-known varieties: (1) *C. theifera*, var. *assamica*, or Assam tea; and (2) *C. theifera*, var. *sinensis*, or China tea. There is no evidence that tea is wild in any part of China. The only part of the world where tea is really known to grow wild is in the forests of Assam. The Assam variety, known as 'indigenous' tea, is a tree of vigorous growth attaining a height of 30 to 40 feet, with a leaf from 8 to 10 inches in length. The China variety is a comparatively stunted shrub, though hardier, growing to a height of 12 to 15 feet, with a rounder leaf about 3½ inches in length, and calyx covered with soft short hairs. These two varieties have resulted in a hybrid which combines the hardy character of the China with the other features of the indigenous, now largely cultivated on the hills of India and Ceylon, and known as 'hybrid-Assam.' At low elevations where the climate is tropical the indigenous, or a hybrid nearly approaching it, is preferred. It is probable that the Chinese variety is the indigenous, changed by climate and cultivation. The hybrids vary much in productiveness, and the planter is careful in selecting a good strain, which grows and foliates freely without seeding. The branches are smooth.

China Tea (*Camellia theifera*), young shoot with flowers: *a*, fruit. (Bentley and Trimen.)

The leaves are serrated and have a bright shining surface, are rather thin, but often tough and leathery. The flowers are often handsome, usually white, and are about 1¼ in. in diameter; sometimes solitary, sometimes clustered in masses; they have very short flower-stalks or no stalks at all. The fruit is rather short, of a leathery or woody consistency; dry, not fleshy. Inside it is divided into three to five three-celled chambers. Linnæus gave the name *Thea sinensis* to the Chinese variety of the tea-plant, but afterwards made two species, *T. bohea* and *T. viridis*, under the impression that black and green tea were the products of different plants. Mr Fortune was the first to show that both kinds of tea were made from the same shrub. The Chinese name for tea is *tcha*, in the Fuh-kien dialect *té* or *tch*.

The tea-plant will flourish in all parts of the tropical and subtropical zones where the rainfall is over 60 inches and evenly distributed throughout the year. In Ceylon (lat. 7° N.) it grows from sea-level to an altitude of 7000 feet. At a low elevation the growth of the plant is more rapid, but in time the high-grown tea seems to produce as much leaf as the average of low-country estates, while the tea is of more delicate flavour, though

inferior in strength. At Darjeeling (27° 3′ N. lat.) it grows at 7000 feet above sea-level. In China and Japan it is cultivated to the 40th degree N. lat. At Auckland, New Zealand (36° 50′ S. lat.), it grows in the Domain gardens. At Natal (30° S. lat.) it is regularly cultivated, and the tea is of good flavour and strength. One circumstance, however, rules the successful production of tea—the price of labour. Roughly speaking, it may be said to take the labour of one man a day to produce a pound of tea. In Ceylon the daily pay of a coolie man is 8d., children and women being paid from 4d. to 6d. Hence it is evident that no country where labour is dear can compete with countries like India, Ceylon, Java, and China, where labour is cheap.

The tea-plant is not particular as to soil, but it succeeds best on new forest-land containing plenty of humus. Belts of forest should be left for shelter in windy situations, and a reserve of forest for firewood and timber for chests is most important. If the machinery in the tea-factory can be driven by water-power a great economy is effected by saving fuel. As is the case with cacao, coffee, and other economic plants, tea grown on rich alluvial soil is stronger than tea grown on poorer land, though the latter is often of more delicate flavour. Tea-factories range in value from £200 to several thousand pounds; some are lighted by electric light. Tea-making goes on night and day in the busy seasons.

Cultivation.—The clearing is made by cutting the undergrowth with heavy socket-knives, after which the forest-trees are felled and the largest branches lopped; six weeks afterwards the wood is burned. In Ceylon this is done by contract for 20 rupees per acre. Tea is planted in rows from 3½ to 5 feet apart, with a similar distance between the plants; 4 × 4 feet being a favourite distance, which gives 2722 plants to the acre. The tea-seed is soaked in water, and planted in shaded nursery beds; when the plants are about 4 inches high they are transplanted to the holes in wet weather during the monsoons. When plants are scarce the seed may be sown at stake in the holes, but nursery plants are generally preferred. The clearing is roaded and drained as soon as possible. On the rich deep soils of Assam manuring is not practised. In Ceylon the favourite manures are cattle-dung, castor-cake, bones, nitrogenous manures, and those which contain potash. When the plants have been in the ground about fifteen to eighteen months they are cut down to 10 or 12 inches; this makes them spread, and strengthens the growth of the branches. In about two months the more vigorous shoots are nipped back below the second leaf, thus taking off the terminal leaf-bud and first and second leaves, which makes the axillary bud at the base of the third leaf develop a fresh shoot. At first plucking is rather a matter of pruning than of gaining leaf, but as the trees become stronger the plucking becomes more regular and heavier. At about three years the bush is again cut down to some 15 inches flat across, so as to leave two joints of new wood above the last pruning. In subsequent prunings all bark-bound wood must be removed, along with whippy branches which do not 'flush' or develop fresh shoots. The plucking is done with the thumb-nail, and the leaf must on no account be torn off. Only the youngest and most tender leaves are plucked; and the younger the leaf, the finer the tea. The largest leaves used are never more than 2½ inches long. The estate must be plucked in regular rotation every ten days or a fortnight. When tea is flushing well a good coolie can bring in from 20 to 30 lb. of green leaf in a day.

In China the cultivation of tea is very different from the Indian and Ceylon system. There are no large gardens, the tea being grown in small fields and on hillsides. The leaf is plucked from the latter part of April to the end of October. The small farmer imports coolie labour for the purpose from the more populous districts. The grower does not manufacture the leaf himself, but sells it green in the local market at the nearest head village. The green leaf is bought by the agents of Chinese capitalists, who have hongs where they manufacture and pack the leaf. The finest pickings are described as first chop, the next as second chop, and so on. The hong-man ships the tea in boats, and sends it down the rivers uninsured. Before the tea is exported it has to pay the imperial Chinese customs export duty, which amounts to 1¼d. the pound; the lekin duty is nearly as heavy.

Chinese teas may be classified thus: Monings or black leaf teas are grown in the north of China, and shipped from Hankow and Shanghai. They come from the following districts: Ningchow (mostly bought for Russia), Kintuck, Keemun (shipped chiefly to England), Kutoan, Ichang, Oopack, Oonam, Oonfa, Ly Ling, Cheong-sow-kai, Hohow, Siangtam. Green teas are shipped from Shanghai, and consist of Gunpowder, Imperial, Hyson, Young Hyson, and Twankay. Kaisows or Red-leafs are grown farther south, and are shipped from Foo Chow. The different kinds which take their names from the districts in which they are grown are Seumoo, Panyong, Paklum, Pakling, Padrae, Saryune, Sucy Knt. From Foo Chow are also shipped Souchongs, which are a distinct kind from Congous, and are principally drunk in Germany and Austria. Fancy teas, consisting of Oolongs, Flowery Pekoes, and Scented Orange Pekoes, are exported from Foo Chow. Canton exports Congous called New-makes, Scented Capers, and Scented Orange Pekoes.

The United States and Canada consume nearly all tea exported from Japan, the estimated supply in 1891 being 47,000,000 lb. The teas exported from Japan are of light character, mostly Oolongs and greens. The total quantity of tea imported into the United States was, in 1888–89, 79,575,984 lb., and in 1889–90, 83,886,829 lb.

Manufacture.—The first process is to spread the green leaf thinly on hessian trays in the withering house, where it is exposed to a free current of air—a very important operation, which takes from 12 to 48 hours. When the leaf is tough and flaccid, like an old kid glove, it is ready for rolling. Withering is assisted by fans which circulate currents of dry air. The old or Chinese system of rolling was to place the withered leaf on a table where it was rolled by hand to and from the coolie till the juice was expressed and the leaf well twisted; this took about 20 minutes to do. The Chinese accomplish this partly by the dirty process of treading. Now this process is performed by machinery, and in India and Ceylon tea is not manipulated after plucking. In Jackson's 'Excelsior' and 'Rapid' tea-rolling machines in general use in India and Ceylon the leaf is rolled between two superposed plates of hard wood or polished granite, actuated by cranks which give them a compound circular or eccentric motion. These machines are driven by steam or water power, but there is a smaller roller for hand power. Both the 'Excelsior' and 'Rapid' rollers are capable of taking a charge of from 240 to 300 lb. of withered leaf, they effect a great saving in labour, do the work far more thoroughly than by hand or foot pressure, and ensure perfect cleanliness. Some planters sift the rolled leaf through sieves with ¼-inch meshes and re-roll the leaf which is too large to pass through. Considerable diversity of opinion exists as to

whether tea should be rolled lightly or hard: the former gives a prettier tea with more of the golden 'tip;' the latter gives a stronger liquor, and the tea keeps better. The rolled leaf is now ready for fermentation, an operation requiring close attention. It is placed in drawers or on tables and covered. The state of the weather hastens or retards the process; in hot dry weather the leaf will be sufficiently fermented or oxidised in 20 minutes, in cold wet weather it may take hours. Whenever the leaf assumes a bright copper colour it must be fired; over-fermentation is a fatal error. The difference between black and green teas is simply this: if the tea is fired immediately after rolling it is green tea, if it is fermented it becomes black tea. The old system of firing was to have iron gauze trays fitting over V-shaped chula furnaces about 30 inches high, and to dry the tea over charcoal fires. Now drying is done quicker and better by machines for the purpose, such as the 'Sirocco,' consisting of a stove portion and drying chamber, through which a powerful air-current passes; and by this means the wet leaf is dried thoroughly in 6 to 8 minutes. Other machines are known as the 'Britannia' and the 'Desiccator.' Jackson's 'Victoria' and 'Britannia' driers are highly recommended, and Brown's desiccator is well spoken of in Ceylon. After firing the manufacture is complete, and the tea is what is known as 'unassorted,' which contains all the different grades into which tea is usually separated. In this state it is a most excellent tea for drinking, but it is customary to sort it into different grades before sending it to market. The old system of doing this was by using hand sieves of different sizes. The 'dust' was taken out by the finest sieve; the 'broken pekoe' or finest and youngest leaf by the next; the 'pekoe' by a sieve with wider meshes; the 'pekoe souchong' by the next larger; if 'souchong' is made a still larger meshed sieve is employed. Sorting by hand sieves is still done in small factories, but in large factories machinery is used. Jackson's 'Eureka combined tea sorting and cutting machine' is in general favour. Before the final packing the tea is taken from the bins in which it is kept and re-dried to expel any moisture which it may have absorbed from the atmosphere. It is then weighed into lead-lined chests, half-chests, or boxes, and soldered up, the name of the garden is stencilled on the packages, and it is ready for export. Chests usually contain 100 lb. of tea, half-chests from 45 to 50 lb., and boxes 20 lb. The 'brick tea' prepared at Hankow for overland exportation to Russia is made of tea-dust steamed and pressed into cakes, which occupy only one-sixth of the bulk of loose tea. A coarser kind, made of tea-leaves, stalks, and refuse of the tea-dust cakes, is sent to Mongolia, where for use it is boiled with mutton fat and butter. The Burmese eat pickled tea with fish, &c.

History. — De Candolle states that tea was known to the Chinese before 519 A.D.; a Chinese legend says tea was introduced into China by Djarma, a native of India, about 500 A.D. Tea first became known to Europeans about the end of the 16th century. Small quantities were brought to England early in the 17th century, but it was not till about the year 1657 that it began to be used as a beverage, when Garraway opened a tea-house in Exchange Alley; the price then was from £10 to £5 per lb. Pepys, writing on 28th September 1660, says: 'I did send for a cup of tee (a China drink) of which I had never drank before.' Two years later he writes: 'Home, and there find my wife making of tea, a drink which Mr Pelling the Pothicary tells her is good for her cold and defluxions.' In 1678 the English East India Company imported 4713 lb.; in 1725 370,323 lb. were drunk in England; in 1740 the prices ranged from 7s. to 24s. per lb.; in 1775 the consumption was 5,648,000 lb.; in 1801, 23,730,150 lb. In 1840-90 the consumption in the United Kingdom has been (1840) 32,000,000 lb., (1850) 51,000,000, (1860) 77,000,000, (1870) 110,666,390, (1880) 158,571,000, (1890) 194,008,000; and it has increased from 1·22 lb. per head in 1840 to 5·07 lb. in 1890. In 1840 the duty was 2s. 2¼d. per lb.; in 1858, 1s. 5d. per lb.; in 1865, 6d.; and in 1890, 4d. per lb.

About 1820 the plant was discovered wild in Assam, and was again noticed in 1823. The attention of the East India Company having been called to the expediency of introducing tea into India, a commission was sent to China in 1834 for this purpose. It was, however, recalled when Dr Griffith and Dr Wallish proved tea to be growing wild in Upper Assam between the Naga and Mishmee mountains on the upper part of the Brahmaputra River. The same year the Company commenced the industry at Kumaon with plants brought from China. In 1835 the first garden in Assam was opened at Luckimpore, from which a small quantity of tea was sent to England in 1838. In 1840 the Assam Tea Company was started, and in 1843 Indian tea offered for sale in London fetched from 2s. 6d. to 3s. per lb. The first garden of indigenous tea was planted by the Assam Company in 1840, and the value of the variety was gradually recognised; though large quantities of China plants and seed were imported in 1848 and 1851. The industry in its early days passed through many vicissitudes, but the perseverance of those engaged in the cultivation was attended by success. There are now about 312,000 acres under tea cultivation in India, the leading districts being Assam, Cachar, Sylhet, Darjeeling, Dooars at the foot of the Darjeeling Hills, Dehra Dun, Kumaon, and Kangra, Chota Nagpore, Chittagong, the Neilgherry Hills, and Travancore. Export of tea from India (year ending 31st March 1886), 69,666,116 lb.; (1887) 80,557,329 lb.; (1888) 88,982,346 lb.; (1889) 99,339,868 lb.; (1890) 105,609,533 lb.; (1891) 101,903,655 lb.

Tea was introduced into Ceylon in 1839. In 1867 Mr James Taylor opened the first clearing on Loolcondura for Messrs Keir, Dundas, & Co., but it was not till 1874–75 that the cultivation became common. On the failure of coffee from the 'leaf disease' fungus about 1881 and onwards there was a rush into tea, and the staple cultivation of the colony was changed. In 1867, 10 acres were under tea; in 1877, 2720 acres; in 1887, 170,000 acres; in 1891, 223,000 acres. The exports were (1873) 23 lb.; (1877) 2105 lb.; (1880) 162,575 lb.; (1884) 2,392,973 lb.; (1888) 23,820,723 lb.; (1889) 34,346,432 lb.; (1890) 45,390,086 lb.; (1891) 68,274,420 lb. As in Southern India, there is no winter in Ceylon and vegetation receives no check, hence tea is made more or less in every month of the year. The crop in Natal is about 300,000 to 400,000 lb., and is consumed in the colony, Free States, and Transvaal. The tea is of fair quality when made by experienced planters, having something the character of Ceylon. Java ships tea of taking appearance but often of weak liquor. In 1888–89 the export was 7,659,000 lb., and in 1889–90 7,056,000 lb. About 70,000 acres are planted. China teas were formerly much adulterated with foreign leaves, various mineral substances, sand, quartz, magnetic oxide of iron, soapstone, &c. These were cleverly made up so as to resemble the various kinds of tea with starch, and were known as 'lie tea.' Dr Hassall found from 8·32 to 24·94 per cent. of mineral matter in caper; in siftings, 15·32 per cent.; in gunpowder, 8·49 to 33·49 per cent. Infused tea-leaves, redried, were also commonly used. Thanks to the care taken in the laboratory at the London Custom

House, adulteration may be said to be a thing of the past to the English consumer, as the detected teas are not allowed to pass into use in Britain, though they may be again shipped abroad. Mineral matters are, however, still allowed for facing purposes to the extent of 2 per cent., the object of facing being to improve the appearance of inferior tea. The substances used are generally Prussian blue, indigo, soapstone, and plumbago. The caper tea much used in the midland counties is faced with plumbago. Spurious leaves are easily detected by macerating in hot water and examining under the microscope. Although, owing to the increasing cultivation of tea in India and Ceylon, the amount grown in China has decreased, it is still a most important industry. In 1885 the total amount of tea exported from China was 283,833,466 lb.; in 1897 it had fallen to 204,288,500 lb., of which 30,029,666 lb. went to the United Kingdom, 108,485,866 lb. to Russia, 27,718,366 lb. to the United States, 15,952,016 lb. to Hong-kong, 4,433,600 lb. to Australia, &c. In India in 1897 there were under tea-cultivation 423,932 acres, and the value of the tea exported to the United Kingdom alone amounted to £5,450,541. In Ceylon in the same year the acreage under tea was 404,574, and the value of its exports to the United Kingdom was £3,728,166, while in 1878 the total value of the Ceylon tea-crop was only £120.

While in 1864 all the tea imported into the United Kingdom (85,799,253 lb.) came from China, except 2,800,000 lb. from India, and Ceylon tea was unknown till 1880, in 1897, of a total of 231,399,778 lb. imported and entered for home consumption, 17,242,274 lb. only were from China. Of the remainder, 124,534,194 lb. were from India, and 85,493,534 lb. from Ceylon. It is satisfactory to know that markets for Indian and Ceylon tea are gradually being developed with Australia, Russia, North America, and other places. The largest consumers of tea are, in the order named, Great Britain, United States, Russia, Australian colonies, Canada, followed a long way behind by Holland, Germany, France, Austria-Hungary, and Denmark.

Chemistry.—As a beverage, the refreshing qualities of tea are well known. It exhilarates the system, dispelling fatigue and sleepiness, and stimulates the mental powers. These properties are generally believed to be due chiefly to the active principle theine, though the evidence on this point is not clear. We find tea in great favour with weak and old persons, also among the poor, who find that by using tea they consume less solid food. But if tea is used to excess it produces flatulent indigestion, increased pulsations of the heart, and nervousness; the imagination is excited, and sleeplessness follows. These conditions cause a certain degree of fatigue, which induces the patient to have recourse to tea again to brace up the system, as drunkards resort to spirits in the morning for a similar purpose. It is difficult to determine how much tea can be safely drunk daily, the effects on different constitutions being unlike. Johnston considered that 3–4 grains of theine may be taken daily without bad effects, but that double this quantity may be injurious. Dr Bennett (*British Medical Journal*, 1874) found theine was poisonous for cats and rabbits in doses of rather over one grain for every pound-weight of the animal. In medicine theine is used in cases of opium-poisoning, for nervous headaches, to relieve stupor in fevers, and as a sedative of the vascular system; it has also a considerable diuretic action. Theine can be obtained from the infusion of manufactured tea by crystallisation. It is odourless, white, and has a slightly bitter taste. It is generally considered to be identical with caffeine, though this has lately been questioned. It occurs very irregularly in tea, but is found to a greater degree in Indian and Ceylon than in China and Java teas, as is shown in analyses by Dr Paul and Mr Cownley (*Pharmaceutical Journal*, November 19, 1887, and July 26, 1890). From these analyses it appeared that the theine in different kinds of dry Ceylon tea varied from 4·89 to 2·57 per cent., in Indian tea from 4·89 to 3·86, and in Chinese tea it ranged from 3·78 to 2·42.

Tannin is an important constituent of tea, which gives the astringent properties to the infusion. It is generally admitted by chemists that tannin to a great extent regulates the commercial value of tea. Those teas which are rich in tannin give a stronger and darker liquor, and are consequently in greater demand. Tannin precipitates both albumen and peptone, and in this way doubtless hinders digestion. It also stops secretion from the mucous membrane, and so retards the pouring out of the digestive products; otherwise it probably has no effect, when given in small doses as in infusions of tea, on normal persons. When tea is allowed to stand five minutes before pouring off the infusion, which is the time allowed by tea-tasters, probably only one-fifth of the tannin is extracted. But when allowed to stew a long time, as is too often the case in poor households, a much larger percentage of tannin is extracted. Though Indian and Ceylon teas contain more tannin than China teas, it does not follow that the drinker of the former absorbs more tannin into his system than the drinker of the latter, as much less Indian tea is required to make a cup of tea. The percentage of gluten in tea is of little importance. Sometimes the results of analysis are stated for gluten and at other times for albumen, of which it is a form. Albumen (and gluten) is, however, rendered insoluble by boiling water, and so probably remains entirely in the tea leaves. If any were dissolved in the infusion it would probably become a food, like white of egg, fibrin, and other albumens. As yet chemistry throws but little light on the volatile oil contained in tea. Nor is it definitely known whether any of the ordinary effects of tea are due to it. It is possible that it may have something to do with the peculiar flavour of certain teas. The following plan of tea-making for household use is worth attention. Bring the water to the boil, but do not let it boil longer or the water hardens. Use a liberal quantity of tea, and pour over it as much water as you consider will make all the tea you require. Let it stand for three minutes and pour into a fresh (warmed) tea-pot. Five minutes is the longest time the water should remain on the tea.

Money, *Cultivation and Manufacture of Tea* (Lond. and Calcutta, 1878); Johnston's *Chemistry of Common Life* (new ed. 1879); the present writer's *Subtropical Cultivations* (1886); W. G. Stables, *Tea, the Drink of Pleasure and Health* (1883); Owen, *Tea-planter's Manual* (Colombo, 1886); A. M. and J. Ferguson's *Tropical Agriculturist, Tea Culture and Preparation, Tea-plucking Illustrated* (Colombo, various years); and Rutherford's *Ceylon Tea-planter's Note-book* (1889).

Teak (*Tectona grandis*), one of the most valuable timbers known, is the wood of a large deciduous tree (natural order Verbenaceæ) with leaves from 10 to 20 inches in length, and from 8 to 15 inches in breadth. The tree, which has small white flowers in panicles, is found in Central and Southern India, where, however, it is now scarce in some localities in which it was formerly plentiful. There are extensive forests of it in Burma and Siam, and it extends into Java and some neighbouring islands. In India growing teak is placed under the management of a conservator of forests,

and very little is now exported from that country. The wood is of a quiet yellow colour, tending to brown, and like many other kinds of timber has a characteristic odour. It is classed as a hardwood, though it is only of medium hardness, taking, however, a good polish; and it is straight grained and strong. Although easily worked when not long cut down, it readily blunts tools after being kept some length of time. Its average specific gravity when dry is about 585. Teak does not shrink much in seasoning, and it is believed to expand and contract less by differences of temperature than most woods. Unless very thoroughly seasoned it has some tendency to split, and this is perhaps its chief defect. It is much less resinous than some other well-known hardwoods, such as mahogany and rosewood, but it is usually said to contain an aromatic essential oil which prevents iron in contact with it from becoming rusted, and for this reason it is always used for the backing to the armour-plates of ships of war. A sticky elastic extract, to some extent resembling india-rubber, is obtained from teak by treating the wood with naphtha or ether. It is probably this which is the real cause of the wood preventing iron from rusting. The pores of the wood are sometimes filled with a white substance, which has been ascertained to be phosphate of lime (calcium phosphate). There is a high percentage both of this substance and of silica in the ash of teak, and this no doubt explains why carpenters and other tradesmen consider it gritty. White ants rarely attack the wood if it is sound, but nevertheless logs of it are often badly worm-eaten; these, however, are rarely sent to Europe, and are believed to be derived from unhealthy trees. Teak wood varies considerably in quality even when perfectly sound.

In India teak is used for all kinds of work where strength and durability are required, such as for building ships, houses, and bridges; also for the construction of railway carriages and furniture. In England it is largely employed in shipbuilding, and to some extent for architectural purposes, such as shop fronts, as well as for furniture. It has numerous minor applications. The leaves of the tree yield a red dye. Being of large size they are used in India for plates and for thatching. The great increase in the consumption of teak in recent years shows that the wood is much appreciated for its valuable properties. In 1890 the imports into Great Britain were 60,182 loads, value £680,162; while in 1880 they only amounted to 33,800 loads.

African teak (*Oldfieldia Africana*) is imported from the west coast of Africa; it is also a valuable timber, but less so than true teak.

Teal (*Querquedula*), a genus of very small ducks with numerous widely distributed species. The

Common Teal (*Querquedula crecca*), male and female.

Common Teal (*Q. creecca*), a beautiful bird measuring 14 inches in length, is comparatively abundant in Britain, breeding freely in the east and north of England, and throughout Scotland and Ireland. Its nest is usually built on the margin of a lake or among heather; it is made of grasses and leaves and lined with down. The bird feeds chiefly at night on worms, slugs, insects, and seeds. The Garganey (*Q. circia*) is also a British species, but is much less common, and breeds regularly only in Norfolk and Suffolk. It is larger than the common teal, the adult male measuring 16 inches. The Green-wing Teal (*Q. carolinensis*) of North America closely resembles the common teal, the females of the two species being hardly distinguishable from each other.

Tears usually consist of pure water, with saline traces; but in cases of poisoning may show the poison, and in diabetes become saccharine like the other secretions. The lachrymal apparatus is described at EYE, Vol. IV. p. 509. Serving normally to moisten eyeballs, interior eyelids, and nose, they are regularly secreted in normal quantities, and disappear by the duct into the nose. Where there is spasmodic contraction of the muscles about the eye, as in fits of coughing, yawning, or immoderate laughter, the tears are squeezed out from the eyelids and run down the cheeks. In man they are also the natural outlets of strong emotion, and are secreted in greatly increased quantity; they much more constantly accompany crises of fear, anxiety, grief, affection, and keen joy than physical pain. Old age is comparatively tearless. Some animals, especially deer, are credited with weeping tears of grief. Darwin says few animals shed tears at all; he failed to notice weeping in monkeys, but records Emerson Tennent's opinion that elephants weep with sorrow, as supported by the keepers of tame elephants. See Darwin's *Expression of the Emotions* (1873).

Teasel (*Dipsacus*), a genus of plants of the natural order Dipsaceæ. This order consists of herbaceous and half-shrubby exogenous plants, with opposite or whorled leaves, and flowers in heads or whorls, surrounded by a many-leaved involucre. There are five known genera and 125 species comprised in the order, all natives of the temperate parts of the Old World. In the genus Dipsacus the flowers are separated from each other by long, stiff, prickle-pointed bracts. The only valuable species of the order is the Fuller's Teasel, or Clothier's Teasel (*D. fullonum*), a native of the south of Europe, naturalised in some parts of England. It is a biennial, several feet high, with sessile serrated leaves, the stem and leaves prickly; and with cylindrical heads of pale or white flowers, between which are oblong,

Fuller's Teasel (*Dipsacus fullonum*): *a*, a bract.

acuminated, rigid bracts, hooked at the point. The heads are cut off when the plant is in flower, and are used in woollen factories, and by fullers and stocking-makers, for raising the nap on cloth. No mechanical contrivance has yet been found to equal teasel for this purpose, to which the hooked points, the rigidity, and the elasticity of the bracts are admirably adapted. The heads of teasel are fixed on the circumference of a wheel or cylinder, which is made to revolve against the surface of the cloth. Teasel is cultivated in many parts of Europe, and is imported into Britain, but is cultivated to some extent in England, particularly in Somersetshire and Yorkshire. The seed is sown in March, on well-prepared, strong, rich land, and the plants thinned out to a foot apart; in August of the second year the heads are ready to be cut. The flowers of teasel abound in honey, and the seeds are used for feeding poultry. The root was formerly in use as a diuretic and sudorific.

Teb, El, 50 miles SSE. of Suakin, was the scene, on 29th February 1884, of General Graham's defeat of Osman Digna's forces, that victory being preceded by Baker Pasha's defeat near Tokar (4th February), and succeeded by the second British victory of Tamanieb (13th March).

Technical Education, of such a kind as best to fit the youth of the country for their work in after life, is especially necessary in the case of those on whose work depends the material welfare of the nation—artisans, foremen or employers, farmers or merchants or commercial travellers. The public interest in the subject was aroused by the fact that in 1881, when a Royal Commission was appointed to consider the question, education in Britain was in this respect very much behind that provided in such countries as France, Germany, and the United States of America.

The methods of technical education are necessarily different in different countries. On the Continent the growth of the industrial system has accompanied or rather followed that of the technical schools. These have thus been able to render very great direct assistance to the industries; while even the injurious effect of compulsory military service has been much diminished by the inducement to higher technical study involved in the offer of a shortened period of service to students who have passed successfully through a technical school. In Britain long-continued industrial supremacy has led to a well-developed industrial organisation in which the old opportunities for the trade education of apprentices in the workshops have largely disappeared, and their place is only now being filled by outside teaching. In Britain, moreover, the difficulty of reorganisation is increased by the power of trade societies, which insist upon the letter of the apprenticeship period although its spirit is gone.

In the earlier stages of education the aims and the conditions are practically the same in all countries. The subjects of instruction and the methods of teaching must be such as will best train the intelligence, the observing and reasoning powers, and pave the way for manual dexterity. In the teaching of arithmetic every opportunity must be taken to connect figures with facts, and pupils must be accustomed to solve the simple problems of price and measurement that are of constant occurrence in daily life. English language and composition is not only valuable as a medium for literary culture, but it is technical in so far as it leads to the accurate description of an object, a process, or an event, or to the full understanding of such a description. Drawing offers a ready means of training the hand and eye; while modelling and the use of tools are valuable aids in this important relation. The accurate study of common things ought to form an essential part of the training of the pupils who have to acquire habits of inquiry; it is also the foundation of that familiarity with properties of materials which is the basis of good work in the industries. It is this study of common things which is known as 'Elementary Science' in school programmes. Throughout the elementary stage of education it is the method as much as the matter that constitutes the claim of the work to be described as technical.

In Britain the higher stages run along two parallel lines—the one for pupils who devote their time to systematic study, and for these the teaching is carried on in day classes; the other for pupils who spend the day in work in a trade workshop, in an office, or in the field, and for whom only the evenings are available for instruction in sciences—in the principles underlying their daily work and in languages. Considering day classes first, we find in every town of considerable size secondary schools adapted to the needs of boys from thirteen to sixteen years of age. In most of these adequate instruction is given in technical and commercial arithmetic, in mathematics, and in modern languages. In many towns there are also technical schools in which the training includes moreover free-hand and mechanical drawing, handicraft, and the branches of science that are likely to be of most advantage to the pupils—applied mechanics, steam, electricity for engineering students; chemistry and agriculture for agricultural students, and so on. The great majority of the pupils attending these schools pass from them directly to work, and continue their education by attendance at advanced evening classes, or by attending advanced day classes for a year or two after completing an apprenticeship. Some, however, give up a year or more, when they are from sixteen to eighteen years of age, entirely to study before taking up practical work. This course is followed mainly in industries such as engineering, mechanical or electrical, chemical or textile manufactures, or agriculture, where the processes involve applications of principles which can be fully understood only by those who have studied a fairly wide range of science. The advanced classes for the instruction of such students are to a large extent of a practical kind; much of the work is done in laboratories. All colleges for such work require fully equipped chemical, physical, mechanical, and engineering laboratories, workshops for wood and iron, as well as a full complement of appliances for teaching art, the principles of agriculture, or such other departments of applied science as are required by the students in attendance. It is also desirable that the students should have facilities for continuing their language studies and for becoming familiar with book-keeping and commercial practice. After a course of study such as is provided in a technical college of this kind the students are in a position to benefit very readily by the experience they will have in the manufactory or office or on the farm. They will have thoroughly mastered the principles, and have learned something of the modes of their application, so that they enter upon their work with their eyes open alike to the possible causes of failure and to likely avenues of advance.

For the benefit of students who are unable to devote their entire energy to study up to the age of eighteen, or even up to sixteen, evening classes have been established throughout the country in which the work ranges through the standards described here as secondary and advanced. It is thus possible for a lad who leaves school for a trade at the age of thirteen or fourteen to continue his studies by attending evening classes, and he will find that by diligent work for four or five

years he may complete the secondary stage of his education, while three or four more will enable him to become familiar with that theoretical knowledge whose applications he has been practising all these years. This prolonged course is required only for those who would fit themselves for any promotion that may be open to them; for the less ambitious a shorter course suffices. For all, however, it is now realised that what is first wanted is a thorough grasp of elementary principles such as will enable a man to make the most of the experience and deftness he acquires in the course of his practical work.

The scope of the technical education required for each of the thousand-and-one occupations of the day is, according to the British view, limited by the accepted conclusion that the best place for a young man to learn the practice of his trade or business is in the workshop or office, as the case may be. But while this is so it is also recognised that there are many matters of general knowledge essential to the due understanding of this practice, many questions of materials, design, principles, and methods which it is nowadays quite impossible for a beginner to be instructed in during business hours, and which can be both more economically and more efficiently taken in hand by an organisation specially charged with such work. A technical school may thus be complete without any teaching of a trade. In fact, in Britain, trade teaching in schools or colleges has been suggested only in the case of a few special industries, and to a certain extent in others for youths in exceptional circumstances.

On the continent of Europe and in America the provision for the technical education of workmen and foremen is not in most respects in advance of that now made in Britain. For masters and managers, however, there have been in active operation for many years numerous technical schools, supported almost entirely by the several states, housed in palatial buildings, equipped with costly and extensive laboratories and museums, and conducted by staffs of professors and teachers so numerous as to admit of the utmost subdivision of the subjects taught. Reporting in 1884, the Royal Commissioners on Technical Instruction declare 'that they had been much impressed with the general intelligence and technical knowledge of the masters and managers of industrial establishments on the Continent. They found that these persons, as a rule, possessed a sound knowledge of the sciences upon which their industry depended, and that they were familiar with every new scientific discovery of importance, and appreciated its applicability to their special industry. They adopted not only the inventions and improvements made in their own country, but also those of the world at large, thanks to their knowledge of foreign languages and of the conditions of manufacture prevalent elsewhere.'

The great proportion of important inventions and improvements in industrial processes that are due to British manufacturers shows that there have ever been men who secured their own technical education when there were little or no apparent facilities for it. A complete system of technical education will widen the area from which such industrial leaders may arise. It will increase the number of those who, having the intelligence and tact essential in a foreman, have also the technical knowledge required to enable them to understand new work. And it will give workmen, in addition to the expertness which retains for them a large share of the markets of the world, the ability to enter into their work with intelligence, with pleasure, and with ambition.

See the Reports of the Royal Commissioners on Technical Education (1884; explaining the systems in use in various countries); vol. ii. of the *Proceedings* of the International Conference (Lond. 1884); the publications of the National Association for the Promotion of Secondary and Technical Education; the reports and prospectuses of the several technical schools; MacArthur, *Education in its relation to Manual Industry* (New York, 1885); C. H. Ham, *Manual Training* (New York, 1886); Sir Philip Magnus, *Industrial Education* (1888); also the articles POLYTECHNIQUE, EDUCATION, ART (INSTRUCTION), SLOYD; and for the part taken by the county councils in promoting technical education, see Ashby, *Manual of the Guild and School of Handicraft* (1892).

Technology, the systematic knowledge of the industrial arts, represented by innumerable articles in this work, such as those on spinning, weaving, calico-printing, the manufactures of cotton, woollen goods, silk, the making of the several metals, gas, sulphuric acid, bread, beer, wine, &c.

Teck, an ancient principality named from a castle on 'the Teck,' a limestone peak in the Swabian Alb, 20 miles SE. of Stuttgart. Held by various families from the 11th century on, it passed in 1498 to the Dukes of Würtemberg. In 1863 the king of Würtemberg conferred the principality on Duke Albert of Würtemberg's son (born 1837), who in 1866 married the Princess Mary of Cambridge. Their daughter, Princess May, was married to the Duke of York, eldest surviving son of the Prince of Wales, 6th July 1893.

Tecumseh (or *Tecumtha;* 1768–1813), chief of the Shawnees (q.v.), who headed the rising suppressed by Harrison in 1811, and passing into the English service commanded the Indian allies in the war of 1812–13 with the rank of brigadier-general. He was killed fighting bravely at the Thames in Canada. See the monograph by Eggleston (New York, 1878).

Teddington, a town of Middlesex, on the left bank of the Thames, 13½ miles (by water 18½) SW. of London. Pop. (1861) 1183; (1891) 10,025.

Te Deum (*Te Deum laudamus, Te Dominum confitemur*), a well-known Latin hymn of the Western Church—so called from its first words—sung at the end of matins on all feasts except Innocents' Day, and on all Sundays except during penitential seasons. The hymn is one of the most simple, and at the same time the most solemn and majestic, in the whole range of Latin hymnology. Its authorship is uncertain. The chronicle of Bishop Datius of Milan (died *c.* 552), which unhappily is both unauthentic and worthless, describes the Te Deum as the joint production of St Ambrose and St Augustine, into which they both burst forth by a common inspiration on occasion of the baptism of Augustine. Hence the Te Deum is commonly called the Ambrosian Hymn. The first actual reference to it is in the rule of Cæsarius of Arles, who was made a bishop in 502, and it is at any rate certain that it arose as early as the 5th century, and in its modern form was used by Hincmar of Rheims in the 9th century. It is ascribed by some authorities to Hilary of Arles, by others to some disciple of Cassian of Marseilles, but in no case is the evidence at all satisfactory. The hymn in its current form consists of twenty-nine verses; the first twenty-one verses are uniform in the four oldest versions current, and it seems probable that verses 1–10 were a Greek hymn dating back to the 2d century, although Bishop John Wordsworth in Mr Julian's *Dictionary* thinks verses 7–9 are a reminiscence of Cyprian, not *vice versâ*, and that the Greek form of verses 1–10 is a translation from the Latin, not an original composition. In the Anglican morning prayer it follows the first Lesson, except when the Benedicite is preferred as its alternative. It is frequently used also in the

services of both Presbyterian and Congregationalist churches, and there are more than twenty metrical renderings of it in English hymnology.

See the Rev. John Julian's *Dictionary of Hymnology* (1892), and Prebendary Edgar C. S. Gibson in *Church Quarterly Review* for April 1884.

Tees, a river in the north of England, rising on Cross Fell, Cumberland, and flowing 70 miles eastward, mainly along the boundary between Durham and Yorkshire, till it falls into the North Sea, 4 miles below Stockton. Owing to works carried out since 1853 it is now navigable to that town for vessels of large burden, those works including the construction of two breakwaters at the mouth.

Teeth, hard bodies in the mouth, attached to the skeleton, but not forming part of it, and developed from the dermis or true skin. 'They present,' says Owen, 'many varieties as to number, size, form, structure, position, and mode of attachment, but are principally adapted for seizing, tearing, dividing, pounding, or grinding the food. In some species they are modified to serve as formidable weapons of offence and defence; in others, as aids in locomotion, means of anchorage, instruments for uprooting or cutting down trees, or for transport and working of building materials. They are characteristic of age and sex; and in man they have secondary relations, subservient to beauty and to speech. Teeth are always intimately related to the food and habits of the animal, and are therefore highly interesting to the physiologist; they form, for the same reason, important guides to the naturalist in the classification of animals.'

True teeth consist of one, two, or more tissues, differing in their chemical composition and in their microscopical appearances. 'Dentine,' which forms the body of the tooth, and 'cement,' which forms its outer crust, are always present; the third tissue, the 'enamel,' when present, being situated between the dentine and cement. The *dentine*, which is divided by Owen into hard or true dentine, vaso-dentine, and osteo-dentine, consists of an organised animal basis, disposed in the form of extremely minute tubes and cells, and of earthy particles. The tubes and cells contain, besides the calcareous particles, a colourless fluid, which is probably transuded blood plasma, or *liquor sanguinis*, and contributes to the nutrition of the dentine. In hard or true dentine the *dentinal tubes* proceed from the hollow of the tooth known as the *pulp cavity*, in a slightly wavy course, nearly at right angles to the outer surface. 'The hard substance of the tooth is thus arranged in hollow columns, perpendicular to the plane of pressure, and a certain elasticity results from these curves; they are upright where the grinding surface of the crown receives the appulse of the opposing tooth, and are horizontal where they have to resist the pressure of contiguous teeth. The tubuli also receive the plasma transuded from the remains of the vascular pulp, which circulates by anastomosing branches of the tubuli through the dentine, maintaining a sufficient though languid vitality of the system. The delicate nerve-branches on the pulp's surface convey sensations of impressions affecting the dentine—sensations of which every one has experienced the acuteness when decay has affected the dentine, or when mechanical or chemical stimuli have "set the teeth on edge."' When a part of the primitive vascular pulp from which the dentine is developed remains permanently uncalcified, red blood is carried by 'vascular canals' into the substance of the tissue. Such dentine is called *vaso-dentine*, and is often combined with true dentine in the same tooth, as, for example, in the large incisors of certain rodents, the tusks of the elephant, and the molars of the extinct megatherium. When the cellular basis is arranged in concentric layers around the vascular canals, and contains 'radiated cells,' like those of bone, this is termed *osteo-dentine*, and resembles true bone very closely. The *cement* always corresponds in texture with the osseous tissue of the same animal, and wherever it occurs in sufficient thickness, as on the teeth of the horse or ox, it is traversed like bone by vascular canals. Moreover, when the osseous tissue contains minute radiated cells, precisely similar cells are likewise present in the canal, and constitute its most marked characteristic. The relative densities of dentine and cement vary according to the amount of earthy matter. In the complex grinders of the elephant and some other animals the cement, which forms nearly half the mass of the tooth, wears down sooner than the dentine. The *enamel* is the hardest of all the animal tissues, and contains no less than 96·4 per cent. of earthy matter (mainly phosphate of lime), while dentine contains only 72 per cent., and cement and ordinary bone only 69 per cent. of earthy matter. The earthy matter is contained in comparatively wide canals, composed of animal membrane of extreme tenuity.

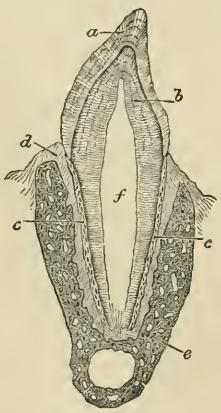

Fig. 1.—Vertical Section through a Tooth lodged in its socket:

a, enamel; *b*, dentine; *c*, crusta petrosa, or cement; *d*, lining of the cavity in the gum; *e*, bony socket in gum; *f*, pulp cavity.

In a few fishes the teeth consist of a single tissue —a very hard kind of non-vascular dentine. Teeth consisting of dentine and vaso-dentine are very common in fishes. Dentine and cement constitute the grinding teeth of the dugong. In the teeth of the sloth the hard dentine is reduced to a thin layer. 'The human teeth and those of the carnivorous mammals appear at first sight to be composed of dentine and enamel only; but their crowns are originally, and their fangs are always covered by a thin coat of cement. There is also commonly a small central tract of osteo-dentine in old teeth. The teeth called compound or complex in mammalia differ as regards their composition from the preceding only by the different proportion and disposition of the constituent tissues. Fig. 2 is a longitudinal section of the incisor of a horse; *d* is the dentine, *e* the enamel, and *c* the cement, a layer of which is reflected into the deep central depression of the crown; *s* indicates the coloured mass of tartar and particles of food which fills up the cavity, forming the "mark" of the horse-dealer.' Far more complex forms of teeth than this may be produced by peculiar arrangements, chiefly inflections, of the tissues (see LABYRINTHODONTS). Another kind of complication is produced by an aggregation of many simple

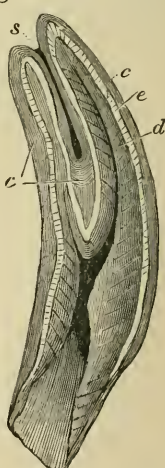

Fig. 2.—Longitudinal Section of the Incisor of a Horse.

teeth into a single mass, as in some fishes and a few mammals. The teeth of the Aard-vark (q.v.) are of this kind, each tooth being composed of a congeries of long and slender prismatic denticles of dentine, which are cemented together. In the elephant the compound molars belong to this class, the denticles being in the form of plates vertical to the grinding surface, and transverse to the long diameter of the tooth.

The teeth of *fishes*, in regard to their number, form, substance, structure, situation, or mode of attachment, offer a greater and more striking series of varieties than do those of any other class of animals. In all fishes the teeth are shed and renewed, not once only, as in mammals, but frequently during the whole course of their lives. Tortoises and turtles, toads, and certain extinct Saurians are toothless. Frogs have teeth in the upper, but not in the lower jaw. Newts and salamanders have teeth in both jaws and upon the palate; and teeth are found on the palate as well as on the jaws of most serpents. In reptiles, as a general rule, the base of the tooth is anchylosed to the bone which supports it. The completion of a tooth is soon followed by preparation for its removal and succession, the faculty of developing new tooth-germs being apparently unlimited in this class. The extinct Odontornithes (q.v.) are the only birds with teeth. Of mammals there are a few genera and species devoid of teeth. The true ant-eaters, the pangolins, and the echidna are strictly toothless. The ornithorhynchus has horny teeth, and the whales have transitory teeth, succeeded in the upper jaw by whalebone. The Narwhal (q.v.) has a peculiar development. The elephant has never more than one entire molar, or parts of two, in use on each side of the upper and lower jaws; to which are added two tusks, which are modified incisors, more or less developed, in the upper jaw. The boar's tusks are large and powerful canines. Some rodents have two grinders on each side of both jaws, which, added to the four cutting-teeth in front, make twelve in all; but the common number of teeth in this order is twenty, although hares and rabbits have twenty-eight each. The number of teeth, thirty-two, which characterises man, the apes of the old world, and the true ruminants, is the average one of the mammals. The dentition is often summarised as to the number and position of incisors, canines, molars, and premolars, thus: the *dental formula* of the typical mammal is *inc.* $\frac{2}{2}-\frac{2}{2}$, *can.* $\frac{1}{1}-\frac{1}{1}$, *pm.* $\frac{4}{4}-\frac{4}{4}$, *m.* $\frac{3}{3}-\frac{3}{3}=44$; or more briefly $\frac{2}{2}\frac{1}{1}\frac{4}{4}\frac{3}{3}$. The absent teeth may be denoted by $\frac{0}{0}$ or by a blank. The dentition is indicated in the articles on the several animals where it is of interest (especially at HORSE), and in the articles on the great groups of animals (see, for example, CARNIVORA). Dolphins may have 200 teeth. (Compare the number of teeth on the tongue of the common garden snail; 135 rows of 105 teeth each—14,175 in all.) It is only in the mammals that we have a well-marked division of the teeth into the four kinds of incisors, canines, premolars, and molars, each of which claims a brief description.

The *incisors*, or cutting-teeth, are situated in front, and possess a single conical root or fang, and a vertical crown bevelled behind, so as to terminate in a sharp cutting edge. These teeth are specially fitted, as their name implies, for cutting the food. In man there are two of these incisors in each side of each jaw (in the pre-maxilla). The permanent incisors, molars, and premolars are preceded by a set of deciduous or *milk* teeth, which are lost before maturity, and replaced by the permanent ones. In herbivorous animals they crop the herbage; in rodents (the rabbit, hare, rat, beaver, &c.) these teeth are very much developed, and differ from any other teeth occurring in mammals in this respect, that their growth continues throughout life; and if their length does not constantly increase, it is because their free extremity or edge

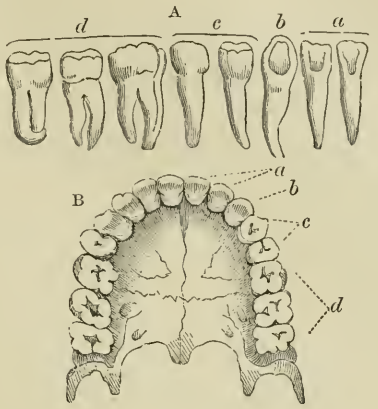

Fig. 3.

is worn down by trituration as fast as they grow at the base from their roots.

The *canines* (so called from their prominence in the dog) come next to the incisors. Their crown is rather conical than wedge-shaped, and their fang sinks more deeply into the jaw than in the case of the incisors. In all carnivorous animals they are largely developed, being obviously formed for tearing the flesh of their prey. In man there is one canine tooth in each half-jaw; and there is never more than this number in any of the lower animals.

The *premolars* (known also as bicuspids and false molars) come next in order to the canines; they are smaller than the latter, and their crown presents two pyramidal eminences. In man there are two premolars in each half-jaw. Their function more nearly approaches to that of the true molars behind them, than to that of the canines.

The *true molars* (or multicuspids) are placed most posteriorly. They are remarkable for their comparatively great size, the square form of the upper surface, on which are from three to five elevations or cusps, and for their short root, which is divided into from two to five branches, each of which is perforated at its extremity. They appear first in the permanent set. In man there are three molars in each half-jaw, the posterior one being termed the wisdom-tooth, from its being cut the latest; they are especially employed for grinding the food, under the action of the muscles of the lower jaw.

The teeth are so admirably adapted for the special purposes which they are called upon to fulfil that it is generally easy, from a careful examination of them, to say to what class of animals they belong, and to draw various conclusions regarding the habits and structure of the class generally. Thus, in carnivorous animals the molars are not grinding-teeth, but present sharp cutting edges, and those of the upper and lower jaw overlap each other, resembling a pair of scissors in their action. In insectivorous animals the molars have a tuberculated surface, with conical points and depressions, so arranged as to lock into each other. In frugivorous animals, living on soft fruits, these teeth are provided with rounded tubercles, while in herbivorous animals they have a broad, rough surface, resembling a millstone.

There is also a close connection between the articulation or joint of the lower jaw and the nature of the food used by the animal. Thus, in purely carnivorous animals, in which the teeth simply tear and cut the food, no grinding motion is required, and the jaw is capable only of a simple hinge-motion in the vertical plane; while in herbivorous animals the joint is so constructed as to allow of extensive sliding and lateral motion of the lower molar teeth upon the upper. In man both the form of this articulation and the general character of the teeth point to an intermediate position in relation to food, and form a physiological argument for the mixed diet which general custom has decided to be most natural to our species.

See the articles CARNIVORA, DOG, RODENTIA, SKULL, for illustrations of teeth *in situ;* and besides general works on anatomy, human and comparative, Owen's *Odontography* (1845) and other works, and Flower's *Osteology of the Mammalia* (1886).

DISEASES OF THE TEETH.—Decay (*Caries*) is by far the most common of the diseases which affect the teeth, and consists in a gradual and progressive disintegration of the tooth-substance. Among the chief predisposing causes are hereditary defects of quality; imperfect calcification; pits and grooves in the enamel; overcrowding of the teeth; facilitating the retention of particles of food between them, constitutional disorders; chiefly those affecting the digestive organs; and debilitating causes generally —e.g. over-exertion of nervous and mental energies. The exciting cause of caries has recently been proved by Professor Miller of Berlin to be due to the action of micro-organisms. According to him, 'the first stage of dental caries consists in the decalcification of the tissues of the teeth by acids which are for the greater part generated in the mouth by fermentation,' the agents concerned in the process being micro-organisms and the acid they produce—lactic acid.

Decay is rarely met with on smooth surfaces exposed to the friction of food and the direct washings of the saliva. It usually begins in some pit or groove in the enamel or between the teeth, such points forming a lodgment for the development of the organisms. Once the enamel has been penetrated the decay proceeds more rapidly, spreading laterally beneath the as yet healthy enamel and towards the pulp. The more dense the structure of the tooth the more directly does the decay penetrate in the direction of the pulp, although its progress is not so rapid and its tendency to spread is less. Caries is most common in early life, by far the greater number of cavities making their appearance between the ages of six and eighteen. Its colour varies from pale brown to black, and generally the lighter the colour the more rapid is the decay. Pain may be felt soon after the enamel has been penetrated, or may be delayed until the nerve (pulp) has become almost or quite exposed; yet, strangely enough, it is sometimes altogether absent, particularly in very hard teeth. When the pulp has become nearly encroached upon, the patient's sensations will warn him against taking hot or cold, sweet or acid fluids. Ultimately the pulp becomes exposed, when the pain increases and may become very violent, especially if the nerve be pressed upon by food forced into the cavity by mastication. Should this take place the pulp becomes acutely inflamed and soon dies, when the pain may either cease or go on till an alveolar abscess is formed. The treatment of caries can only be undertaken by the dentist, and varies with the extent and character of the disease. See DENTISTRY.

Periostitis and Alveolar Abscess.—Periostitis is an inflammation of the membrane (periosteum) which covers the roots of the teeth and lines their sockets. It may be either general or local. When general the majority or all of the teeth are commonly involved. Periostitis of this type is usually due to constitutional causes (such as rheumatism), or the effects of some such agent in the system as mercury, or the presence of accumulated tartar about the necks of the teeth. When the disease is local—confined to one or two teeth—it may result from a blow or some such injury, or it may proceed from an inflamed pulp; but by far the most common cause is the presence of a dead nerve, the poisonous products of which are liable at any time to cause violent inflammation at the end of the root. Yet it is not uncommon to find that teeth whose pulp dies and whose substance gradually breaks down and decays away do not give rise to any trouble. When acute periostitis has fairly set in, it and its usual accompaniment, alveolar abscess, are perhaps the most painful affections to which the teeth are subject. The symptoms vary in intensity, though the characters remain the same. A dull aching pain is felt, and is relieved at first by pressure upon the affected tooth; as the inflammation increases in severity the tooth rises slightly in its socket, and becomes exquisitely painful when bitten upon; the gum around it becomes congested, and the throbbing pain is almost continuous.

Alveolar Abscess may be defined as a suppuration around the root or roots of a tooth. It is of two varieties, *acute* and *chronic*. Its causes are those of periostitis, which precedes it, the continuous and throbbing nature of the pain indicating the formation of matter (pus) within the surrounding bone. The face, with the glands about the neck, swell, and the glands exhibit tenderness on touch. The pent-up pus forces its way through the bone to reach the surface of the gum at the point of least resistance, which is most often opposite the end of the root or roots (this is popularly known as a 'gum-boil'). It occasionally finds its way along a canal by the side of the root, and discharges at the edge of the gum. Sometimes the discharge burrows downwards to find an exit on the face. This is almost peculiar to the lower teeth, and calls for removal of the tooth affected. With the escape of pus by 'gum-boil' there is a marked abatement in the intensity of the pain, which generally disappears in a few hours and the swelling in a few days. If left to itself, however, the abscess soon assumes the chronic form, the tooth becoming almost if not quite comfortable. This condition may continue for an indefinite period, but there may also be a recurrence of the symptoms in a milder form. Not unfrequently chronic abscesses occur without giving rise to any pain, the only evidence of their existence often being a small fistulous opening on the surface of the gum, from which from time to time pus discharges. Even this last may be wanting. If the abscess resist all treatment, the disease can be cut short by the extraction of the tooth, although many cases can be successfully treated and the tooth rendered permanently useful.

Exostosis is characterised by an increase in the thickness of the cementum, the external of the two hard tissues forming the roots of the teeth. Its forms vary from a small nodule or patch to a quantity sufficient to invest the entire root or roots of the same or adjoining teeth. It is most often caused by slight but continued irritation of the periosteum by caries, or by rapid wearing of the masticating surfaces. Occurring as it sometimes does in teeth otherwise sound, its diagnosis is difficult; its presence may not be suspected till an attempt is made to extract the tooth, which, owing to the enlargement of the fangs, cannot even when loosened be removed without great difficulty. Exostosis may often cause neuralgic pains about the jaws.

Impaction and difficult Eruption of the Wisdom and other Teeth.—It is not uncommon to find certain of the temporary teeth firmly set in the adult jaw, and occupying the place of the permanent ones. In such cases the permanent tooth is usually present in the body of the jaw, but it has been retarded in eruption by being too deeply imbedded in the bone. Impaction may also be due to an abnormal direction of growth. Such teeth may appear late in life after all the others are lost, and the bone overlying them has been absorbed and so exposed them. When these cases do occur they are responsible for the popular but incorrect idea of a third set of teeth. An impacted tooth seldom gives rise to any trouble, unless it be an upper or lower wisdom, *particularly* the latter. The cutting of these teeth is sometimes accompanied by distressing symptoms which may be protracted for months or years, unless they are removed by extraction of the tooth. This condition is usually due to imperfect development of the jaw. The tooth usually takes its natural vertical direction, but, being wedged in between the tooth in front and the ascending portion of the jaw behind, only a small portion of the crown is visible. The overlying gum is apt to be bruised by the occlusion of the opposing tooth in the upper jaw; inflammation is thereupon set up, and being maintained by biting may extend to the surrounding parts. Swallowing becomes painful and the motion of the jaws restricted. When it is evident that there is insufficient accommodation in the jaw for the erupting tooth it should be removed.

Inflammation of the Gums, although not a disease of the teeth proper, is one of the most common causes of their premature loss. It may arise from constitutional causes—chronic dyspepsia, rheumatism or gout—or from the administration of such drugs as mercury or iodide of potassium. Most often, however, it results from the presence of tartar about the necks of the teeth, and lack of thorough cleansing. When due to constitutional causes, their appropriate remedies are called for; but when due to the presence of tartar, this deposit should be carefully removed. See DENTISTRY (*Scaling*).

Absorption of the Alveoli.—The gradual wasting of the bone which surrounds and supports the roots of the teeth, accompanied by a simultaneous recession of the gums, is one of the changes which mark the approach of old age. This wasting may, however, occur in middle life without any visible cause, although the majority of such cases are due to chronic inflammation of the gums, with or without the deposition of tartar. Heredity, or the use of too hard a tooth-brush, may likewise be accountable. The teeth most affected are the front ones; but the reverse of this is not unusual. The gums, especially in front, gradually recede and lay bare the roots; the teeth now become loosened and finally drop out. The treatment consists in the removal of any obvious source of irritation; but when the disease is due to heredity nothing can be done to arrest its course.

Abrasion of the Teeth is a gradual loss of their substance from causes which are purely mechanical. The more common cause is a faulty occlusion of the jaws, but it is also produced by the improper use of the tooth-brush. When the result of malocclusion, it shows itself upon the grinding surfaces of the back teeth and the cutting edges of the incisors, which may become rapidly worn down almost to the gum, the rate of progress being frequently hastened by the common habit of grinding the teeth together. When caused by improper brushing it is seen on the front surfaces.

Erosion of the Teeth, on the other hand, though closely resembling the second form of abrasion, is understood to be due to the secretion of a corrosive acid by the labial glands. It is first seen near the gums as a small concave depression with a smooth polished and often very sensitive surface continuous with the front of the tooth. As it progresses, the pulp recedes, throwing out successive layers of protective dentine until it becomes entirely calcified. The disease can generally be arrested by filling, preferably with gold or porcelain inlays.

Diseases of the Antrum, while springing from other sources, are often caused by diseased teeth. The cavity in the bone of the upper jaw, known as the Antrum of Highmore, communicates by a small opening with the nose, and is sometimes the seat of inflammation set up by the presence of an abscess in connection with one of the back teeth, the roots of which project into it. The most common symptom of such a condition is an offensive discharge from the nostril of the affected side, increased in quantity when the patient lies down. The treatment is very tedious, much depending upon the age and general health of the patient; it consists in the removal of any diseased teeth from the affected side. This extraction may be followed by a discharge of pus; if not, an opening into the antrum should be made through the socket of one of the roots, and the cavity drained, suitable stimulating and disinfecting lotions being injected by means of a syringe till a healthy condition is established. Among the less common forms of disease which attack the teeth and gums are necrosis, dentigerous cysts, odontomes, epuloid and polypoid and other tumours of the jaws, and diseases of the tooth-pulp itself. These, however, are so comparatively rare as to be of no interest to the general reader.

Toothache is not so much a disease as a symptom. Its chief causes are mentioned under *Caries* and *Alveolar Abscess*. The pain, which varies greatly in degree, character, and duration, depends largely upon its cause, and the health of the patient at the time of the attack. Only a transient uneasiness may in some instances be felt, and, as often, in others almost insupportable agony. If neuralgic in character it most frequently occurs in paroxysms at more or less regular intervals. When toothache is due to caries with or without simple exposure of the pulp, the attack is brought on by taking hot or cold, sweet or acid fluids, and is seldom of long duration. To afford relief in such cases as these, gently wash out the cavity with a solution of carbonate of soda; then, drying it carefully with a piece of cotton-wool, take a very small pellet of wool dipped in eucalyptus oil and place it in the bottom of the cavity; over this place a piece of cotton-wool large enough to fill the cavity and saturated with the following solution: 1 drachm of mastic in 1½ ounce of Eau de Cologne. This should be changed daily. When the pain is caused by the forming of an alveolar abscess the tooth will be found insensitive to change of temperature but very susceptible to pressure. The patient now becomes feverish, and the pain, which is at first of a dull heavy character, becomes more intense, throbbing, and continuous, till pus has been formed and discharged through the gum. Provided the tooth is likely to prove useful and the patient cannot consult a dentist, the gum should be carefully painted with tincture of iodine, or the old-fashioned plan of placing a roasted fig over the root may be resorted to; at the same time it is well to give an aperient such as Epsom salts, followed by a full dose of quinine—6 to 8 grains for an adult. Great relief follows this treatment, which is, of course, only temporary. If an abscess shows signs of pointing upon the gums it may with advantage be lanced. Poultices *must never* be applied to the face, for heat tends to draw

the pus outwards. Abscesses in connection with the lower wisdoms often assume a very serious character unless cut short by extraction of the tooth.

Hygienic Care of the Teeth.—Many of the diseases of the teeth and gums might be prevented or greatly retarded by proper attention to the cleansing of these organs. The implements best fitted for this purpose comprise the quill toothpick, waxed silk thread and brushes, with suitable powders. The toothpick ought to be used after *every* meal, but it should be supplemented by the use, between the teeth, of floss silk, which will remove deposits accumulating where contiguous teeth touch. The brush is used to remove all deposits solid and mucous, and it gives the teeth a bright and polished appearance; its mechanical friction too stimulates the gums to more healthful action. An excellent tooth-powder is composed of precipitated chalk, 2 ounces; light magnesia, 2 ounces; oil of cinnamon, 8 drops; thymol crystals, 4 grains; otto of roses, 10 drops. The teeth should be brushed twice daily, in the morning and in the evening. The manner of using the brush is more important than many people suppose. The general method is to brush horizontally, but a moment's reflection will show that this leaves untouched the very situations most in need of cleansing. The brush, used properly, should be pressed against the teeth and the handle rotated so as to make the bristles sweep vertically between and over them; this, coupled with an up-and-down motion, will thoroughly cleanse the interspaces; the inner surfaces of the back teeth are best cleaned in a like manner, while the corresponding parts of the upper and lower incisors are effectually reached by a vertical drawing movement. The brush should be of medium texture, and the bristles of unequal length, and not too closely placed. A hard-and-fast rule cannot, of course, be laid down for everyone to follow, but in the majority of cases it is advisable to use the powder in the morning and a mouth-wash with the brush in the evening. For the latter purpose the following is good (especially where a tendency to inflammation exists)—tannic acid, 4 grains; rose water, 1 ounce; tincture of pyrethrum, ½ drachm; oil of cinnamon, 10 drops. Over-brushing must be guarded against as carefully as under-brushing lest the gums and the necks of the teeth be injured. During an illness these precautions are doubly necessary as the corrosive effects of many medicines are then added to the evil results of a weakened vitality. The use of a glass tube in taking medicines that contain mineral acids and iron is usually supposed to be a sufficient precaution against the action of such drugs upon the teeth, but this is quite erroneous; the only sure preventative being a weak solution of ordinary baking soda, with which the mouth should be rinsed after *every* dose. The choice of a tooth-powder should be left to the dentist, for many dentifrices which, no doubt, whiten the teeth do so by the action of some agent which is as deadly to the tooth-substance as to the impurities it is meant to remove. Charcoal (so much used) is quite unsuitable because of its gritty nature. As far as the ordinary individual is concerned, the use of brush and toothpick is the limit up to which one can take care of one's own teeth, so that a thorough examination of the mouth once or twice a year by a trustworthy professional man is necessary to check the diseases of the teeth before they have gone so far as to be irreparable. Especially should this be attended to in children. It is almost impossible to overrate the importance of following, at least in the main if not in detail, the hints given above, for when we consider that the teeth are placed at the very gateway of life, it is not surprising that their neglect should be answerable for many of the disorders of the system. And surely precaution is better than cure.

For a more detailed description of the diseases of the teeth, see the works of Litch, Tomes, and Salter.

Teething, the acquirement of teeth, especially of their first teeth, by children from about their seventh month onwards, may take place in strong children without any constitutional disturbance or ailment other than some local irritation or inflammation; many of the infantile diseases once credited to teething being really due to improper feeding (see INFANTS) and neglect of hygiene. But the time of teething is more or less a critical period, especially for the nervous system of the child, and is apt to be associated, especially in sensitive children or such as suffer from rickets, with restlessness, disturbed sleep, and even in some cases with Convulsions (q.v.), diarrhœa, and eruptions. Close attention to the general health is always necessary.

Teetotalism. See TEMPERANCE.

Tegern-See, a beautiful mountain lake, 3½ miles long, in the extreme south of Bavaria, 30 miles SE. of Munich; it is a much esteemed summer-resort.

Tegethoff, WILHELM, BARON VON, Austrian admiral (1827–71). See TACTICS, p. 46.

Tegnér, ESAIAS, one of the most prominent of Swedish poets, was born at Kyrkerud, in the province of Vermland, on 13th November 1782, the son of a country pastor of peasant descent. The boy lost his father when only ten years of age, and owed his education as well as his support to the good-will of kind patrons. At seventeen he enrolled himself a student at Lund University, and graduated, as first student of his year, in 1802; a few months later he was appointed a lecturer in the faculty of philosophy. It was not until 1808 that he attracted any attention as a poet; but the stirring *War-song for the Militia of Scania* made his name known, and the patriotic appeal, *Svea* (1811), made it famous. In the following year he was chosen professor of Greek. The best creations of his poetic genius all belong to a comparatively short period of time (1817–25)—*Song to the Sun* (1817), *Epilogue on the Degree Day at Lund* (1820), *The Candidate for Confirmation* (1820), *Axel* (1821), and *Frithiof's Saga* (1825). After this he only wrote occasional pieces and a couple of incomplete poems of a more ambitious cast. In 1824, however, he had been called to undertake the onerous duties of the bishopric of Vexiö, and to those duties he gave his strength, until symptoms of mental disease showed themselves (1840); he died 2d November 1846 (see SWEDEN, p. 9). His work is distinguished by much of the transparent clearness, tranquil ease, and artistic finish that he admired so greatly in the ancient Greeks. At the same time he writes with the warm enthusiasm, the quick poetic feeling, the freshness and vigour of a modern over whom the inspirations of romanticism had passed. And, what has contributed not the least to make him a favourite, his verse is full of melody, rich in imagery, and moves with stately grace and dignity. *Frithiof's Saga*, a cycle of epics treating of old Scandinavian days, is his masterpiece; and notwithstanding certain obvious faults, it is a noble production, one of the most popular poems in Swedish, and a welcome addition to the translated poetry of every literature in Europe. *Axel*, a romance in verse of the time of Charles XII., is more unequal in execution; the other three poems mentioned rank higher than *Axel* in technique, but do not surpass its best passages in poetic insight and inspiration. Tegnér's collected works were published in 1847–50 (7 vols.

Stockholm), and again in 1882–85 (8 vols.). The best life is that by his son-in-law, Böttiger, prefixed to the first edition of his collected works. See also the interesting monograph (in Danish) by Georg Brandes (1878).

Tegucigalpa, the capital of Honduras, is situated in a fertile valley 3400 feet above the sea, on both sides of the Rio Grande, with mountains rising round about. It has a high school, an active trade, and a pop. of 12,000.

Tehâma. See ARABIA, Vol. I. p. 362.

Teheran, or TEHRAN, capital of Persia, 70 miles S. of the shore of the Caspian Sea. It stands on a wide plain, dotted here and there with mud-built villages, and pierced with many circular pits, which reach down to the great subterranean watercourses, on which, in this region, the life of animal and plant is altogether dependent. To the north runs in a general east and west direction the lofty range of the Elburz Mountains, rising in Demavend to the height of nearly 20,000 feet above sea-level. The old wall and ditch (4 miles long) were levelled in 1868, and the space thus gained made into a much needed circular road or boulevard. Fortifications, consisting of a bastioned rampart and ditch, were at the same time commenced on a much more extended scale. This enceinte, with its twelve gates and enclosing an area about 10 miles in circumference, was completed in 1873. The town rapidly extended beyond its old limits, more especially on the north side, where many fine streets, gardens, and buildings soon made their appearance, among which may be specially mentioned the handsome buildings and grounds of the British Legation. The Shah's palace, entirely reconstructed since 1866, occupies the Citadel, and is both spacious and cheerful, its large courtyards being laid out with gardens and numerous fountains. Besides his town palace, the Shah has five others in the immediate neighbourhood, which he occupies at different seasons of the year. The foreign legations and rich natives are also in the habit of resorting in summer to the cool slopes at the foot of the Elburz, where many of them have commodious houses and fine gardens. The bazaars, some of which are very handsome structures, are filled with every kind of native and foreign merchandise. From Teheran lines of telegraph radiate in almost every direction to the extremities of the kingdom, by far the most important being the lines of the Indian Government Indo-European Telegraph Department and those of the English Indo-European Telegraph Company. In 1886 a short line of railway was constructed from Teheran to Shah Abdul Azim, a shrine and place of pilgrimage about 6 miles to the southward of the town. Tramways were also laid down in different parts of the city; and gas was introduced (by a Belgian company) in March 1892. The population probably amounted in 1900 to 230,000, about double what it was fifty years before. In the same period the number of Europeans increased from about 30 to 1000. In the vicinity of Teheran are the ruins of Rei, the *Rhages* of the Book of Tobit, known in the time of Alexander the Great under the name of *Rage* and the birthplace of Harûn-al-Raschid. See PERSIA, and works there cited.

Tehuantepec, a town of Oaxaca, Mexico, 10 miles above the mouth of the river Tehuantepec, with 25,000 inhabitants (mostly Indians) within its municipality. The isthmus on which it stands is only 120 miles wide, and a canal here between the two oceans has been dreamt of ever since Cortez' day. A concession was granted and an Anglo-American company formed in 1850; but the political insecurity of the country and the construction of the Panamá railway combined to bring it to an end. An interoceanic railway company founded in 1879 also allowed its concession to lapse; Captain Eads's ship-railway remained a project only; but an ordinary railway was finally opened in the year 1894.

Teignmouth (pron. *Tinmouth*), a seaport and watering-place of Devonshire, 12 miles (by rail 15) S. of Exeter, stands on the north side of the pretty estuary of the Teign, which is spanned by a wooden bridge (1827), 557 yards long. Burned by the Danes in 970, by the French in 1338 and 1690, it has a grassy promenade, the Din or Dune, a pier (1866), a public market (1883), baths (1883), St Scholastica's Abbey for Benedictine nuns (1865), &c. Pop. (1851) 5149; (1891) 8292.

Teinds, the name given in Scotland to tithes or the proportion of the annual produce of the earth devoted to the maintenance of the clergy. The growth of the system in Europe is recounted at TITHES. In Scotland personal teinds are practically unknown; and predial teinds, natural or industrial, drawn from the fruits of land, constitute the whole teinds leviable by the church. Predial teinds are of two kinds, parsonage and vicarage. The parsonage or greater teinds, due exclusively to the parson serving the cure, are payable out of grain at the terms Whitsunday and Michaelmas. Vicarage or lesser teinds are properly paid to the vicar, and are drawn from minor and accidental products, such as fowls, eggs, milk, fish, &c., according to the usage of each parish or benefice. Parsonage teinds being an inherent burden on the land, the right to levy them cannot be lost by prescription; vicarage teinds, on the other hand, being established both as to their kind and their amount solely by use, may be lost by non-use. By statute, 27 and 28 Vict. chap. 33, provision is made for vicarage teinds on fish being commuted.

The teinds due at common law to the incumbent of the parish had previously to the Reformation been to a large extent diverted to other purposes, with the result that the acting parochial clergy were greatly impoverished. In many cases, on a vacancy occurring in a parochial charge, the patron, acting as absolute proprietor of the benefice, appropriated its teinds to a monastery or other religious house, and although the disposal of tithes to laymen had been prohibited by several Lateran Councils, grants of part of the teinds of vacant benefices were frequently bestowed by patrons on needy lay friends and relatives. Further, a considerable proportion of teinds was diverted from the support of the parochial clergy by the practice of certain popes in granting to various orders of churchmen exemptions from the payment of tithe out of lands held by them. Soon also a custom grew up of granting feus of these church lands *cum decimis inclusis*, a provision which transferred to the grantee the same exemption from the payment of teind which the ecclesiastical proprietors had formerly enjoyed. In these various ways the revenues of the church had been extensively impaired long before the Reformation.

At the Reformation the great bulk of the church lands was acquired by the crown, either by resignation or annexation. The monasteries and priories fell at first into the hands of lay commendators, appointed by the king for life; but later they were erected into temporal lordships, the grantees being styled *Lords of Erection* or *Titulars of the Tithes*. In this way the possessions of the church were permanently transferred into the hands of laymen holding of the crown. The property of the lands erected and the right of exemption from teind, where such right existed, formed the temporality; while the teinds themselves constituted the spirituality of the benefice. For some years the

presentations to vacant benefices were wholly in the hands of the lords of erection, and they also had the power of assigning to the presentees such stipends as they chose. Under the scheme known as 'the assumption of thirds,' however, a return was ordered of the rental of all ecclesiastical benefices within the kingdom, and factors were appointed to uplift one-third of the revenues thereof. This scheme, after being ratified by parliament, was subsequently adopted as the basis of the plan adopted for the support of the reformed clergy. By statute 1587, chap. 29, the practice of creating lords of erection received a check, and, with certain exceptions, the church lands which had been held of the crown before the Reformation were again inalienably annexed to the crown. On the restoration of bishops the annexations of their benefices and of their chapters were rescinded by 1606, chap. 9 and 1617 chap. 2 respectively; on the re-establishment of presbytery these measures were repealed by the Act 1690, chap. 29, and since that date the bishops' teinds have continued to be applied by the crown to public uses and pensions.

In spite of the assumption of thirds and other measures, the provision for the support of the reformed clergy continued very precarious till the accession of Charles I. Immediately after his accession in 1625 Charles, in view of the extent to which the property and revenues of the church had been dilapidated, executed a revocation of all grants of church lands and tithes made by James VI. to the prejudice of the crown. Next year there followed another revocation, conceived in even more ample terms, under which a reduction was brought of all erections whatever, whether made before or after the Act of Annexation. As the individuals who had profited by the prodigality of the crown were very numerous, these proceedings caused wide-spread alarm, and a strong petition or remonstrance was addressed to Charles, with the view of obtaining some modification of his demands. Eventually a compromise was agreed upon, and the parties principally concerned entered into four submissions, under which the whole question in dispute was referred to the determination of the king himself. By the decrees-arbitral, pronounced on the 2d September 1629, the king's right to the superiorities of erection was affirmed, and power was given to the heritor to have his teinds valued and his yearly charge thus permanently settled. Further, the proprietor was found entitled to bring an action of sale against the titular or his tacksman, by which he could obtain right to his teinds at nine years' purchase of the value where the seller had an heritable right. The provisions of the decrees-arbitral, relating to the superiorities of erections and the valuation and sale of teinds were subsequently ratified by a series of acts of parliament in 1633. In 1627 a commission, known as the 'Commission of Surrenders and Teinds,' had been appointed, and in 1633, for the purpose of carrying the decrees-arbitral into effect under judicial authority, another commission was nominated known as the 'High Commission' or the 'Commission for the Plantation of Kirks and the Valuation of Teinds.' These commissioners were instructed to prosecute and follow forth the valuation of all the teinds, parsonage and vicarage, that were yet unvalued; they were authorised to appoint sub-commissioners within presbyteries and parishes, and to them was committed the duty of modifying a constant local stipend to every minister to be paid out of the teinds of each parish. From time to time this commission was continued with increasing powers, or rather, a succession of commissions was kept up until at the Union their power and functions were vested in the Court of Session, where accordingly actions for the valuation of teinds now proceed at the instance either of a heritor or of the minister. The jurisdiction of the Court of Session in modifying stipends, &c. is treated under article STIPEND.

The teind was originally made effectual in Scotland as elsewhere by the beneficiary *drawing* it, that is, carrying off from the ground every tenth sheaf. This practice was very inconvenient, as the proprietor was obliged to allow the crop to remain on the ground, exposed to all the vicissitudes of the season, till the teind was drawn. Consequently, even prior to the Reformation, it was common for the beneficiary to commute his teind either for a fixed yearly payment of money or for a certain number of *rental bolls*. Teinds are *debita fructuum*, not *debita fundi*, and, consequently, arrears of teinds do not affect singular successors. Although prescription, as we have stated, cannot destroy the right to teinds, yet it is effectual to protect an old decree of valuation from challenge, except on the ground of some nullity *ex facie* apparent. The free or unexhausted teinds (i.e. such as, arising from increased rental, &c., are not yet appropriated for stipends) were in 1891 stated at about £129,000. See STIPEND, AUGMENTATION, FIARS.

Tekna, the independent country south of Morocco, extending from the Draa to Cape Bojador, inhabited by Moors and Arabs, many of them nomadic. There is one small port, Tarfaya. Cape Juby is a feature of the coast.

Telegraph (Gr. *tēle*, 'far off,' and *graphō*, 'I write'). This is a general name for any means of conveying intelligence other than by voice or by the transmission of written messages. Perhaps also the idea of speed is generally understood. Alarm fires (see BEACON), the Semaphore (q.v.), and Signalling (q.v.) as used at sea are among the earlier forms of telegraphy, but now all such agents are thrown into the shade by the electric telegraph.

Copyright 1892 in U.S. by J. B. Lippincott Company.

The idea of telegraphic communication by means of magnets is certainly more than two and a half centuries old. In 1632 Galileo, the great astronomer, referred to a secret art by which, through the sympathy of magnetic needles, it would be possible to converse at great distances. Again, in 1753, when a more defined idea of electricity had begun to dawn, a letter appeared in the *Scots Magazine* signed 'C. M.' (now almost certainly recognised to be Charles Morrison, a native of Greenock, who practised as a surgeon at Renfrew, from whence the letter was dated), in which 'an expeditious method of conveying intelligence' from one place to another by means of electric power was so clearly set down that we cannot but recognise that the writer must have had a considerable appreciation of the possibilities of electric communication. Many quiet workers occupied this field of research from that time until 1837, which is the generally recognised year of the birth of the electric telegraph. Limited space forbids anything but a passing reference to the work of the fathers of the telegraph. If a comparison may be made, we may say that what Wheatstone and Cooke were in the Old World, Morse and Alfred Vail were in the New. The claim that may justly be made for the recognition of the genius of either workers does not in the least militate against the recognition of that of the others; but it must be conceded that while the method originated by the English inventors has found acceptance principally in England, the Morse system is of world-wide use, and has supplanted the other even in England except for railway working, for which the needle system is most admirably suited. We must now proceed to furnish such information as will give some idea of the present state of the

science, with some notice of the more important systems in use in Britain, together with a few general statistics. In doing this it will be necessary to assume on the part of the reader some general knowledge of the chief features of Electricity (q.v. ; and see also MAGNETISM).

The general subjects dealt with occur in the following order, and it may be noted that special terms have been included and explained as far as possible. I. *Construction*—(1) lines, overhead and underground ; (2) poles and insulators ; (3) wire ; (4) earths and earth-currents ; (5) circuit ; (6) batteries—universal battery. II. *Apparatus*—(1) needle system and Morse code ; (2) the sounder system ; (3) the Morse recorder ; (4) the relay, polarised and non-polarised ; (5) the double-current system ; (6) type-printing instruments—Hughes's, &c. ; (7) the duplex system ; (8) the quadruplex system ; (9) multiplex telegraphy ; (10) automatic telegraphy ; (11) 'news' circuits ; (12) repeaters ; (13) submarine telegraphy—cables. III. *Statistics.*

I. *Construction.*—(1) *Telegraph lines* may be either overhead or underground. There can never be any question when the choice is open as to the adoption of the overhead system, as not only is the first cost less, but it is better for working purposes, and faults can be easily traced and removed. On the other hand, climatic conditions do not affect underground lines, while a severe storm will sometimes do so much damage to open work as to cripple the whole system. Nearly all the wires in large towns are necessarily underground, as there are many serious objections to overhouse lines. For instance, there are more than 2600 wires led into the Central Telegraph Office in London which are almost without exception underground.

(2) *Poles and Insulators.*—Overhead wires are supported for the most part upon *creasoted* wooden poles by means of *insulators.* No hard and fast rule can be given as to the number of poles that should be used. For minor lines twenty or twenty-two may be used, but on main lines the number should be between twenty-six and thirty to the mile. Ordinarily the lowest wire on a pole should be not less than 12 feet from the ground, so that, allowing for setting in the ground (which varies from 4 feet to 6 for ordinary poles), and the *sag* or *dip* of the wire between the poles, the length of the poles used on branch lines is usually about 20 or 22 feet, and this is increased by 1 foot for each two additional wires required. The object of the insulator is to isolate the wire from any material which would be liable to conduct the current from the wire, and the material of which the insulator is made is therefore of much importance. *Glass* is a material which possesses some of the necessary qualifications in a high degree, but its extreme readiness to condense moisture, whereby it becomes coated with a conducting film, is fatal to its employment. *Ebonite* also fails in practice, and *brown earthenware* is almost the only substance that has hitherto been able to stand out as a competitor with *porcelain.* This latter is distinctly the best material to use, but earthenware has the advantage as regards price. Cordeaux's screw insulator is constructed simply to screw on the bolt so that it can be easily renewed or removed. When insulators are very subject to breakage by stone-throwing they are protected by an iron cap.

(3) *Wire.*—The wire used is either galvanised iron-wire (i.e. iron-wire coated with zinc) or, for special purposes, hard drawn copper-wire. Underground wires are laid in cast-iron pipes provided with *flush boxes* at intervals which provide means of getting at the wires at intermediate points for testing, tracing faults, &c. These wires are of copper coated with gutta-percha. A 3-inch pipe will take as many as eighty wires.

(4) *Earths.*—In 1838 Steinheil discovered that, if a good electrical connection is made with the ground at each end of a single line, the earth will act as a substitute for a return wire. This was a very important discovery, for not only does it save the expense of a return wire, but it also reduces the resistance of the line by nearly half, with several attendant advantages. The technical expression 'earth' is applied to this connection, and an 'earth' may consist simply of a wire attached to a metal plate of a large surface buried in soil that is sure to be always damp ; but metal pumps, or better still the iron water-pipe system in towns, will generally form excellent earths. Iron gas-pipes will do very well in default of water-pipes, but on no account must *leaden* gas-pipes be used, as there is a possibility of a discharge of lightning fusing the pipe and causing an explosion or a fire by igniting the gas. *Earth-currents.*—From causes as yet unexplained different parts of the earth are frequently at different potentials, so that, if two such points be connected by a wire joined to earth at each end, it is traversed by an *earth-current.* Such currents vary during different periods of every day, and at certain periods they acquire such strength as to be termed 'electric storms.' They then may often render ordinary working impossible, and on long cable circuits may even endanger the safety of the cable. In order to secure communication in such circumstances it suffices, where practicable, to use a return wire instead of earth. Lines whose terminations run north-east and south-west are most liable to interruption.

(5) *Circuit.*—This term, which is of very frequent use, implies the whole path along which a current of electricity may be supposed to flow ; that is, for instance, the battery, lever of key, line-wire, coils of receiving apparatus, and the 'earth' at each end. *Short-circuit* implies that the circuit between two particular points (say the two ends of a coil of wire) is bridged across by a conductor of no resistance.

(6) *Batteries.*—The batteries most commonly used for telegraph purposes are bichromate, several forms of Daniell's, and two or three forms of Leclanché, but latterly secondary batteries have been introduced with great success. Ordinarily each set of apparatus at an office has a separate battery, but by a well recognised law of electricity the *universal battery* system is often applied where several circuits of much the same resistance terminate in one office. This means that several sets of instruments (usually not more than five) are joined up to a common battery, each of course working independently. The battery in this case necessarily wants more frequent renewal, but the first cost is less, and there is also a material saving in space, which is of very great importance in such cases—for instance, as at the Central Telegraph Office in London, where there are nearly 24,000 cells in use.

Fig. 1.

II. *Apparatus.*—(1) *The Needle System.*—In the earliest form of telegraph instrument, devised by Cooke and Wheatstone, five needles were used, each worked by two wires ; this number was subsequently reduced to two, and now a single needle only is employed. Fig. 1 shows the dial of such an instrument. The

needle normally hangs vertically, and is capable of motion to the right and left between two stops. The signals are formed by combinations of the two directions of deflection. The alphabet in general use, which is shown above on the face of the dial, is due to Professor Morse, and is hence called the 'Morse Code.' The letters most frequently used—*e* and *t*—are represented respectively by a deflection to the left and to the right. All the other letters of the alphabet are formed by two, three, or four combinations—the length of the signal for each letter being arranged with approximate reference to the frequency of its occurrence in ordinary English writing. In the same way the numerals, stops, and other signals are formed. The figures are represented by *five* signals, thus :

(1) . — — — —	(6) — . . . .
(2) . . — — —	(7) — — . . .
(3) . . . — —	(8) — — — . .
(4) . . . . —	(9) — — — — .
(5)	(0) — — — — —

and the stops, &c. by six combinations. The dots and dashes represent respectively deflections to the left and right. Figures, however, are always spelt in full on the single needle. The needle system is specially English, and is used almost universally for railway telegraphs throughout the three kingdoms. It has no equal for working a large number of offices on one circuit, and it has the great advantage of being extremely easy to learn and simple to work.

(2) *The Sounder System.*—For commercial telegraphy, however, the sounder system is distinctly the most generally serviceable of hand-worked systems. Opposite the poles of an electro-magnet is placed a soft-iron cross-piece or *armature*, fixed upon a lever which is so pivoted that a spiral spring attached to the end of one arm tends to hold the armature away from the poles of the magnet. The passing of a current through the coils causes the armature to be attracted, and its motion is limited by two adjustable screws which are so arranged that the two sounds emitted when the end of the lever strikes upon them are easily distinguishable. Sound-reading then consists really of noticing the intervals of silence between these two sounds. The Morse code as shown above is used, and (1) a *dot* is represented by a very short interval of silence between the downward stroke and the upward stroke of the armature lever; (2) a *dash* is represented by an interval three times as long; and in the same way the *space* between (3) the elements of a letter; (4) the letters of a word; and (5) the words of a sentence are represented by intervals between the downward and the upward strokes respectively equal to one, three, and five *dots*. The instrument by which these signals are spaced out at the sending station is called a *key*. A *single current key* consists simply of a lever so

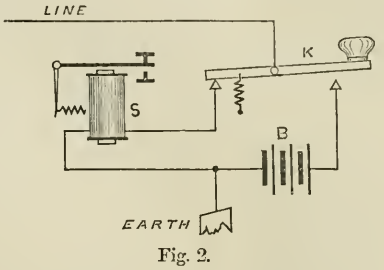

Fig. 2.

pivoted as to make electrical contact with one or two stops. This is shown diagrammatically at K in fig. 2, where B represents the battery and S the sounder. Normally a spring holds the lever of the key in the position shown, so that signals sent from the other stations pass from line to the lever of K, thence by way of the back stop through the sounder to earth. When, however, the handle of the lever is pressed a current passes from the battery, B, by way of the front stop and the lever of the key to the other stations. Thus the duration of the signals received at a distant station is determined by the periods during which K is depressed.

(3) *The Morse.*—It will be at once evident that a permanent record of the signals received may often be of considerable importance ; hence, even before the introduction of the sounder, many devices for securing a permanent record were put forward. One of the earliest was the *Morse Embosser*, whose modern representative is known as the *Writer* or *Inker*. As shown in fig. 3, the

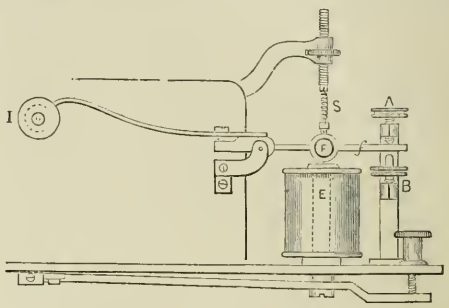

Fig. 3.

combination of the electro-magnet, E, with the armature, F, fitted upon the lever, *f*, which is adjustable by the stops, A, B, and the spring, S, is virtually a sounder, the lever of which is prolonged beyond the pivot and fitted with a small disc, I, kept constantly rotating in a well of ink ; above this inking disc a strip of paper is moved forward by clockwork, so that whenever the armature is attracted by the electro-magnet the disc makes ink-marks upon the paper of a length proportioned to the period of attraction. Thus the *dots* and *dashes* of the Morse code can be recorded.

(4) *The Relay.*—For such instruments as the sounder and the ink-writer, however, where a comparatively considerable mechanical effect is required in order to secure satisfactory signals, a current must be used of such a strength as for a long line would absorb an inconveniently large amount of battery power. To obviate this a *relay* is introduced. A relay is practically a delicate form of the electro-magnet and lever of the sounder. The coils are wound with a finer and longer wire—finer only to get increased length of wire in the available space—and all its parts are proportioned with a view to the armature being actuated by very weak currents. The lever and limiting stops, which in this case are electrically insulated, are made to act as a key, and by this is introduced a *local battery* situated at the receiving station, and by means of which the sounder or other receiving instrument is actuated. The forms of relay are very numerous ; but they may be divided into two groups—*non-polarised*, which are actuated alike by currents in either direction ; and *polarised*, in which the armature, being either itself a magnet or permanently magnetised by a magnet placed in close proximity, is actuated according to the direction of the current. The form which is now most commonly used in England is the Post-office standard relay, the principle of which will be easily understood from fig. 4. Two coils, A and B, are fitted upon soft-iron cores having projecting

pole-pieces, and are so fixed that two soft-iron armatures, *n*, *s*, fitted upon a common axle, may play between them. These two armatures are polarised by the magnet, N′S′, brought near to their axle, and the two coils are joined up so that on the passing of a current their adjacent poles are of opposite polarity. Thus, if a current pass which makes the upper end of A of north polarity, the upper end of B will be of south polarity; A will therefore tend to repel *n*, and B will attract it; similarly (because the lower ends of A and B are then respectively south and north) *s* will be repelled from A and attracted towards B. All the forces therefore tend to move the armatures in the same direction, and so produce a very sensitive combination. The contact lever is fitted upon the axle with the armatures, and the contact stops are placed on either side.

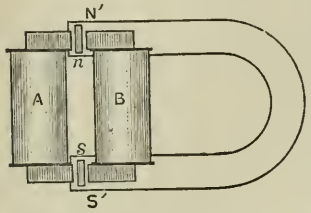

Fig. 4.

(5) *Double-current System.*—The value of the polarised relay arises from its use in connection with the *double-current* system; the principle of which is so to arrange the key and the battery that during the time of transmission there is always a current passing to line, this current being in one direction when the key is up, and reversed when the key is depressed. Thus, with a polarised relay the 'spacing' current holds over the relay tongue to the spacing side, so that the spring or other power otherwise required for this purpose may be almost dispensed with; and consequently the relay will be actuated by a much less powerful 'marking' current than would be required for single-current working. In fact, double current expedites working, reduces the current required (and so tends to increase the working distance of a telegraph line), facilitates the intercommunication of several stations on a single circuit, and is a very important feature in an extensive system.

(6) *Type-printing Instruments.*—Many ingenious devices have been made in order to secure a record of messages sent not merely in a 'code,' but in plain printed characters. Fig. 5 is a fac-simile of a

PRINTING INSTRUMENT

Fig. 5.

piece of slip printed by means of the Hughes Type-printer. The action is principally mechanical, the electrical part being confined to the transmission and reception of a single current of short duration for each letter or other sign registered. The sending apparatus is like a piano keyboard with the letters and other signals engraved upon the keys; but the mechanism is so complex and so sensitive that only the most skilled operators can be entrusted with its working. It is not used in England except for circuits which are in communication with the continental systems. Other printing systems are in use by various private news agencies. They generally require a current for every step forward of the type-wheel—say twenty-six currents to repeat a given letter (although it is really more)—but many ingenious arrangements are made for them, including a device by Mr F. Higgins of the Exchange Telegraph Company which prints in column form instead of merely on a continuous slip.

(7) *Duplex System.*—The rapid increase in the business of telegraphy has called forth the exercise of the ingenuity of telegraph engineers to increase the capacity of a single wire for the transmission of messages. Duplex telegraphy is one way by which this has been effected. By this system messages can be sent on one line in both directions at the same time, thus practically doubling the carrying capacity of the wire, because station A can transmit a message to station B while B is sending another message to A. Under ordinary circumstances, when A is working to B on the open circuit principle, any interference on the part of B disconnects his receiving instrument, and so prevents A's signals from being recorded, because the back stop is disconnected (fig. 2). If now it can be arranged that the receiving instruments at both stations can be always in circuit, yet only affected by the currents sent from their own station when these currents interfere with the currents sent from the other station, then duplex telegraphy becomes possible. There are several modes of doing this, but we shall confine ourselves to a description of the *differential* method, which is almost exclusively that adopted in the British postal telegraphs.

If two circuits of precisely equal resistance be open to a current, it will divide itself equally between the two, and the currents in each wire will be exactly equal. If, for instance, the wire, *Zl*E (fig. 6), offer the same resistance as the wire, *Zr*E, the current in *l* will have precisely the same strength as the current in *r*. Now let an electro-magnet be similarly wound with two wires of equal length, one of which is in the circuit of *l*, and the other in the circuit of *r*. If the current through *l* traverse the electro-magnet in the reverse direction to that through *r*, it is evident that if the currents be equal the polarity induced by the one current must be exactly neutralised by that induced by the other current, for the effects are equal and opposite, and there will be no magnetism excited. Thus, as long as the two circuits are intact, the currents which flow will not affect the electro-magnet; but if the currents in *r* be interrupted, those in *l* will excite the electro-magnet, and if those in *l* be interrupted, the currents in *r* will excite the electro-magnet.

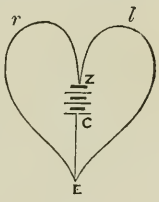

Fig. 6.

Assume A and B (fig. 7) to be two stations connected together by the line-wire, *l*. Let E be an electro-magnet at A, wound as just described, K a key, and B a battery. Let *r* represent resistance coils

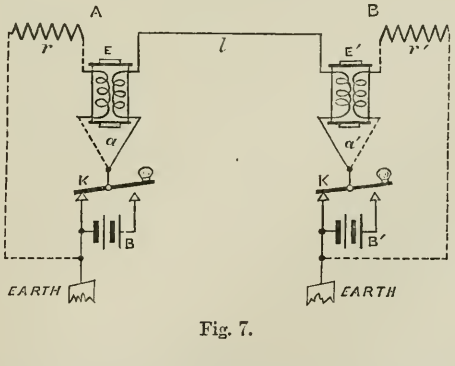

Fig. 7.

or an artificial line, giving a resistance equal to the line circuit. Have a precisely similar arrangement at B, as shown. Now let us in the first place assume A alone to be working to B; every time the key, K,

at A is depressed a current is sent from A's battery. This current divides at *a*, the one half going through the wire in connection with *l* in E, through *l*, and at B, through the wire in connection with *l* in E′, through the key, K′, to earth and thence back to the battery at A. This is called the *line current*. The other half, which is called the *compensation current*, passes around the electro-magnet, E, through the coil in connection with *r*, through *r* and back to the battery. As these two currents are equal, their effect on E is *nil*, but the line current passing through one coil only of E′ operates it and causes signals to be given. Thus while A telegraphs to B its own instrument is not affected, but that at B is actuated. Similarly, when B alone is working to A its own instrument is not affected, but that at A is actuated. But when B is working to A at the same time that A is working to B, what happens? Every line current that leaves A at the same time that a line current leaves B is neutralised. The compensation current at A is now able to excite the electro-magnet, and the armature is moved in precisely the same way as if B's current were received. In the same way B's line currents are neutralised, and its compensation currents move the armature of E′ in precisely the same way as if A's currents were received. Thus E and E′ continue to be worked by their respective stations, regardless of the fact that the line currents are being continually neutralised, so that practically no current flows between A and B, and that they are operated sometimes by the line current and sometimes by the compensation current. Thus, while A sends messages to B, B can be sending messages to A upon the same wire and at the same time.

We assumed that the line current received at A from B was exactly equal to that proceeding from A to B, and that therefore they were exactly neutralised, but it is not so in practice, for owing to the effects of bad insulation the incoming line current is always weaker than the outgoing one. Hence the current received at A from B does not neutralise the whole of the current sent from A to B, but only a portion of it. It so weakens A's current to line that the compensation current preponderates over this resultant current, and the signals are registered by the preponderance. The difference in the strength of these two currents when both stations are working is very nearly equal to the strength of the current received at A when B alone works, so that the marks, whether made by the received line current or by the preponderating compensation current, are practically the same.

We have shown in the diagram that the same poles of the battery are to line, and that therefore the line currents flow in opposite directions; but the same effects occur if the opposite poles are to line, and the currents flow in the same direction. If the current from B flows in the same direction as that from A, the effect, when the two stations work simultaneously, is not to weaken the resultant current, but to strengthen it, and therefore to produce a preponderance of the current in wire *l* over that in wire *r* of relay E, and consequently to register signals; but in this case the marks made at A when both stations are working simultaneously are not made by the preponderance of the compensation current over the line current, but by the excess of the resultant line current over the compensation current.

There are certain irregularities in the working of such a system in actual practice which have to be provided against, due to variations in the resistance and in the electrostatic capacity of the line. Telegraph wires, in fact, are in a constant state of change. If A and B be connected together by an aerial wire supported at intervals of about 80 yards upon earthenware insulators, then the current which arrives at B from A must necessarily be less than that which leaves A, because at each pole a small portion of the current escapes or leaks to earth. No earthenware support is an absolute insulator. Moisture is deposited upon its surface. The amount of this moisture continually varies, and the resistance of the insulator to the leakage of the current varies with it. Hence the difference between the current leaving A and that arriving at B is constantly varying, and the effect upon the current leaving A is precisely the same as if the resistance of the line varied. If moisture be abundant more current leaves A, and the effect at the sending end is the same as if the resistance of the line-wire were reduced, but of course the increased current is not received at the other end. If the insulators become dry, less current leaves A, and the effect is the same as if the resistance of the line were increased. In fact, the resistance of the circuit does vary with the amount of moisture deposited on the insulators, and with the amount of dirt which necessarily adheres to them. Rain, fog, dew, and mist affect it. Lines exposed to the spray of the sea or the smoke of manufactories are peculiarly liable to this variation. Other causes also introduce irregularities which interfere with the constancy of a line. The wires are continually subject to accidents of various kinds, many of which tend to produce variable resistance.

Now what effect has this variation of the resistance of the line-wire upon duplex working, and how is it provided for? Clearly it disturbs the equality of the line and compensating currents, and causes the one to preponderate over the other; and if no means were adopted to compensate for this variation, duplex telegraphy would be impossible. Therefore the resistance in the compensation circuit is not made a fixed quantity, but consists of a series of resistance coils, by which the resistance of the compensation circuit can be varied in consonance with the variation of the line circuit. This instrument is called a *Rheostat*.

The compensation current is then adjusted by the aid of a *differential galvanometer*—i.e. a galvanometer double wound in the same way as the relay coils, the line current passing through one coil and the compensation current through the other in the opposite direction. Thus, when the compensation circuit is properly adjusted, the outgoing current will produce no effect upon the galvanometer.

Another modifying influence present on a telegraph line is *electrostatic capacity*—i.e., in brief, the power which it has of retaining or accumulating a portion of any current passing in it. This also has to be properly represented in the compensation circuit, and this is done by means of *condensers*. This is a term applied in electricity to an apparatus generally composed of alternate layers of tinfoil and paraffined paper (or mica), so arranged and connected as to form virtually a flat Leyden jar of large surface. As the capacity of a telegraph line varies with weather and from other causes, the condenser is also made variable.

It will be seen that satisfactory duplex working demands more skill and attention from the operators than does ordinary working; hence, as there are always times during which the requirements of business do not render it necessary that a circuit shall be worked duplex, and as it occasionally happens that owing to line variations, &c. duplex working becomes temporarily impracticable, all duplex circuits are fitted with switches, by means of which recourse may be had to ordinary working, still using the same apparatus.

(8) *Quadruplex System.*—Duplex telegraphy, as

explained in the last section, means the transmission on the same wire of a message from (say) station A to station B while B is sending another message to A. If A or B be able to send *two* messages to the other at the same time on the same wire we have *diplex* telegraphy; and by combining these two systems—duplex and diplex—we may have four messages being sent simultaneously on a single wire, and this constitutes *quadruplex* telegraphy.

Suggested by Stark and Bosscha in 1855, it was not until 1874 that the problem of quadruplex working was solved by a device of Thomas Alva Edison, and the system now in use is the result of his efforts, supplemented by the work of Prescott, Gerritt Smith, and others. It may be broadly described as the duplex system provided with two keys in the sending circuit, and two relays, each having a coil in both the line and the compensation circuits (*l* and *r*, fig. 7). One key (on the A side of the set) is so connected that when its lever is depressed the battery connections are reversed, so reversing the direction of the current; while the other key (on the B side) is so constructed that the depression of the lever brings into circuit three times as much battery power, so that (whatever the direction of the current) it is increased in strength threefold. The A side relay at the other end responds correctly to the 'marking' and 'spacing' currents whatever their strength, while the relay on the B side is actuated only when the greater current is received, and then responds whether the current is 'positive' or 'negative.'

Since the introduction of the system into the Post-office telegraphs it has been considerably improved and simplified, so that now a battery having an electromotive force of 130 volts will satisfactorily work circuits that at one time required 200 volts, and even then worked indifferently. Among many varieties of useful arrangements of this system may be mentioned the 'forked' system, where, for instance, the London end of a circuit is fitted with full quadruplex apparatus, and the Leeds end is fitted with a special set, by means of which the A side of the London circuit is put in direct communication with Stockton, while the B side is connected to West Hartlepool. Both Stockton and West Hartlepool thus have direct *duplex* communication with London on a circuit common to both from Leeds. There are at present between thirty and forty wires worked on the quadruplex system in Great Britain.

(9) *Multiplex Telegraphy.*—In 1873 Meyer conceived the idea of so arranging two corresponding sets of apparatus at distant places that, by causing them to move in exact synchronism, the use of a telegraph line might be given successively to several operators for a very short period of time, so that one at each end would have it alone during the recurring periods. The synchronous movement of the two sets would ensure that each operator at one end should always have communication with the corresponding operator at the other.

Now that the idea has developed into a practical

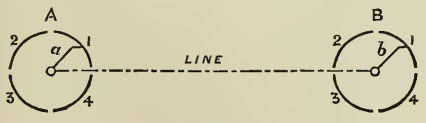

Fig. 8.

system, it is known as the *multiplex* system. Fig. 8 indicates the principle. If the arms, *a*, *b*, which are electrically connected with the line-wire at A and B respectively, be made to rotate simultaneously around the circles 1, 2, 3, 4, making contact with the segments as they pass, then when *a* is on A 1 *b* will be on B 1, when *a* is on A 2 *b* will be on B 2, and so on. Again, if 1, 2, 3, 4 at each station be connected to a set of telegraphic apparatus (say a single-current sounder set), then each of the four sets at A will be successively connected with the corresponding set at B as the arms, *a*, *b*, move over the segments 1, 2, 3, 4. Thus for each revolution of the arms the instruments connected to A 1 and B 1 will be in direct communication once, and so also with A 2, B 2; A 3, B 3; and A 4, B 4.

Now suppose that each of the segments in fig. 8 be again divided into four and connected to each of the four sets of instruments instead of with only one of them (fig. 9). During one complete revolution of the arms each pair of instruments

Fig. 9.

will be in communication four times; and it is clear that if the arms in the two cases assumed be moving at the same rate, then, although the time during which each instrument is connected to line during one revolution of the arms will be the same, in the latter case it will be divided into four smaller periods, each separated by a period of disconnection of only one-quarter the length which occurs in the former case. This subdivision may of course be extended to a very considerable extent, and in practice it is so far extended that the intervals of disconnection are so short that with the apparatus used they may be neglected, so that each set of apparatus may be worked as if it and its corresponding set alone were connected to the line.

Meyer's system proving impracticable was improved upon by Baudot in 1881, but still without success, the difficulty being in maintaining synchronism. Paul La Cour of Copenhagen had in the meantime taken up the question of synchronism, and he invented a very ingenious plan which contained the germ of success. In 1882 Patrick B. Delany of New York perfected a plan for synchronism on La Cour's principle, and in 1884 produced a complete and workable multiplex system.

It will be seen that the principle of multiplex working differs so materially from the principle of duplex or quadruplex that all they really have in common is the capability of the simultaneous transmission of more than one message upon a wire. Hence the application of the same terms duplex, quadruplex, and sextuplex (working three messages each way on the quadruplex or similar principle) to the corresponding arrangements in multiplex working would tend to confusion, and therefore a special nomenclature, based upon the Greek word *hodos*, 'a way,' is adopted. Thus two-way working, that is, a mode of working by which two messages may be sent over the same line on this system, is known as *diode;* three-way, *triode;* four-way, *tetrode;* five-way, *penthode;* and six-way, *hexode.*

The great difficulty to be overcome in order to make the system practical was to secure the synchronous movement of the two arms rotating over the segments. The nearest approach to isochronism can be obtained with two tuning-forks pitched to absolutely the same note and set into vibration under exactly the same conditions, but

the least interference (even a variation of temperature) is sufficient to affect the time vibration.

The instrument with the rotating arms and the segments is called the *distributor*, and its rotating arm is driven by means of a vibrating reed (virtually a tuning-fork) which intermittently completes the circuit of a battery through an electro-magnet in front of the poles of which an iron toothed wheel is fitted, this wheel being fixed upon the same axle as the arm. The reed, R (fig. 10), is simply a flat bar of mild steel firmly clamped at one end. On one side of the free end is placed an electro-magnet, M_1, the circuit of which includes the reed and a light contact spring. If the battery, B, be joined up as shown in fig. 10, the reed will be attracted towards the electro-magnet, and the circuit will thus be broken between the spring and the reed, attraction will therefore cease, and the reed will resume its original position. The circuit will then be again complete, and the same movement will be repeated, so that by this means the reed is maintained in vibration. The circuit of the battery, B, however, includes the coil of the electro-magnet, M, before the poles of which is pivoted the iron toothed wheel, W. When the circuit is complete and the cores of M are magnetised, the teeth of W are attracted to the position shown, but, as the attraction immediately ceases, the momentum that W has acquired is sufficient to carry it on, so bringing the next adjacent teeth within the range of attraction, when the circuit is again complete. Thus the reed is made to cause W to rotate. On tracing the course of the current from battery B it will be noticed that after passing through the electro-magnet, M, it has a course through r_1, without passing through M_1. This coil constitutes what is known as a *shunt* upon M_1, and the current divides between the two in the inverse proportion of their resistance. The current cannot pass at C and r_2, as C—a small condenser—is virtually a point of disconnection. The function of C and r_2 is to prevent sparking at the reed contacts from the discharge of the electro-magnet, M.

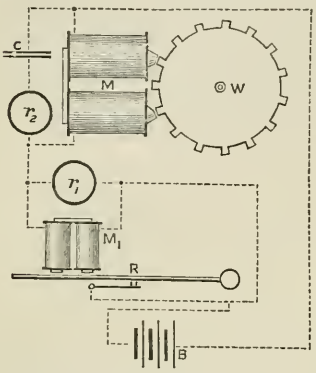

Fig. 10.

The motion of the wheel, W, is regulated by a fly-wheel placed over it; but, as a dead-weight would not accommodate itself to a sudden momentary variation of speed to which the motor may be subject, the fly-wheel consists of a wooden block in which are two deep concentric grooves which are filled with mercury. It is thus really the rings of mercury which form the fly-wheel, and they are not readily influenced by irregularity of running: even if the wheel be actually stopped the mercury continues to move, and will carry on the wheel if the period of stoppage be not too considerable.

In practice it at once becomes evident that the reed at one end of a line cannot possibly be expected to keep absolutely isochronous with that at the other, the result being that the signals sent from the set of segments 1 are received successively upon the receiving segments 1, 2, 3, &c. at the other end. In order to prevent this and keep 1 always to 1, 2 to 2, &c., sets of 'correcting segments' are provided. These are divided into 'sending' and 'receiving corrections,' and are so arranged that when the trailer on the arm, *a*, is upon a sending correction segment the trailer on *b* will be on a receiving correction segment, and *vice versâ*; and if it should be lagging slightly behind its proper position the current will pass to a correcting relay, which will slightly quicken the slower reed. As these corrections can be applied if necessary nine times in each second, practical synchronism is secured.

The number of 'ways' which it is possible to work with this system is principally determined by the static capacity of the line, but a clear description of the theory of this is not possible here.

In actual working with the distributor used in England there are (practically) 162 segments, and 144 of these are grouped at intervals of twelve; so that they form twelve sets, apart from the correcting segments. The time of a complete revolution of the trailer at normal speed is one-third of a second, so that the time of contact with each segment is about $\frac{1}{500}$th of a second, and each group is therefore connected to line for $\frac{1}{5000}$th of a second about thirty-six times per second. Special large relays, wound to a high resistance (1200 ohms) and connected with condensers of a large capacity, are used for receiving. By this arrangement the short impulses are converted into continuous signals, and thus the distributor (by connecting the line consecutively to certain pairs of sets of apparatus, one at each, end at very short intervals) enables each pair to work as well as if it alone had sole use of the line.

The maintenance of good working requires considerable skill and experience, as well as a thorough grasp of the whole principle, and it is necessary to make one station solely responsible for the adjustment of speed, &c.; otherwise the attempts of one station to secure good working may altogether upset similar efforts at the other end.

(10) *Automatic Telegraphy.*—The several kinds of apparatus already described are dependent entirely upon the hand for the transmission of the signals, and this necessarily limits the possible speed of transmission. Even the sounder—the fastest hand-worked instrument now used—cannot be worked by the most expert of operators at a rate exceeding forty-five words a minute. This is, however, by no means the limit of speed at which signals can be recorded even by the simple Morse inker; so that, although dependence upon the muscular motion of the wrist and the directive action of the mind may keep the speed at a comparatively low value, if the manipulation of the human agent can but be replaced by the precision and regularity of a suitably arranged machine, not only can we attain, but far exceed, the highest speed of the ordinary Morse or sounder. Hence early efforts were made to replace the hand-worked key by some mechanical contrivance which would not only remove the defects inherent to manual labour, but would secure precision in the formation of the characters, accuracy in the despatch of messages, and speed in transmission. Bain in the year 1846 was the first to propose this. He punched broad dots and dashes in paper ribbon, which was drawn with uniform velocity over a metal roller and beneath styles or brushes of wire, which thus replaced the key, for whenever a hole occurred a current was sent by the brushes coming in contact with the roller. The recording instrument was his chemical marker. The speed at which messages were transmitted at experimental trials was enormous; 400 messages per hour were easily sent; but when to the defects in the machinery were added the disturbances on the line from causes which were then unknown, it failed to commend itself. Perhaps the real reason for its not being persevered with was that at that time it was really

not wanted; but now that telegraphic business has increased so enormously that extra wires are needed in every direction, apparatus which increases the capacity of the wires, by sending through them a greater number of messages in a given time, has become a necessity.

Wheatstone's system of automatic telegraphy is that which is used in England. Bain's method of punching has been considerably modified, and the messages are recorded on an exceedingly delicate form of direct ink-writer. The apparatus consists of three parts: the *Perforator*, by which the message is prepared by punching holes in a paper ribbon; the *Transmitter*, which sends the message under the control of the punched paper; and the *Receiver*, which records the message at the distant station when thus sent by the Transmitter.

The *Perforator* consists of three levers or keys the depression of which actuates five punches in a certain order, and also a groove and a feed arrangement to guide and move forward the paper as it is punched. The paper used is of a white description dipped in olive-oil. The three keys on being depressed drive the punches through the paper, cutting out clean round holes. The depression of the left-hand key causes the paper to be perforated with three holes in a vertical line thus: o ; the depression of the centre key punches one—centre—hole only, thus: o; and the depression of the right-hand key perforates four holes arranged thus: oo.

The left-hand key corresponds with dots, the centre with spaces, and the right-hand with dashes. It will be noticed that the holes made in the centre of the slip are smaller than those in the upper and lower rows. They admit the teeth of a little star wheel, which is turned through a small space whenever one of the keys is depressed, and which thus moves the paper forward a certain distance for each depression of either key by a species of rack and pinion movement. The space through which the paper is moved for a dash is twice the length of that through which it is moved by either of the other keys. In fact two central holes are punched for each dash required, and the star wheel is made to turn two teeth instead of one as in the case of the other two keys. If left, right, and centre be struck or depressed in succession, we have the paper prepared for the letter A; if right, left, left, left, and centre be depressed in succession, we have the paper prepared for the letter B; and so on for all the letters and signals. The word *Paris* thus prepared is indicated by fig. 11. An expert

Fig. 11.

operator can punch at the rate of about forty-five words per minute, but the average rarely exceeds forty.

The *Transmitter* replaces the key of the ordinary apparatus, and it sends the currents by mechanical means under the control of the punched paper; hence the name of the system—the Automatic.

The arrangements of the parts is such that when running free the electrical portion sends alternate reverse currents of short duration, but when the slip is inserted these reversals are interrupted by means of the action of vibrating pins which tend to pass through the upper and lower holes of the slip. Thus, to take the first letter of the slip shown above: the transmitter would be sending a spacing current when the back pin would rise through the first upper hole and permit a reverse (marking) current to be sent. On the next rising of the front pin it would pass through the first lower hole, and the reverse (spacing) current would pass. Thus a 'dot' would have been sent to line. The spacing current would remain on (for a period equal to the length of a dot) until the back pin again rose through the second upper hole, when the marking current would again be to line. When the front pin again rose its progress would be stopped by the slip, as there is no hole in the lower row beneath the second upper hole, and therefore no reversal would take place; the same applies also to the next rising of the back pin, and the marking current would therefore remain on until the occurrence of the second lower hole permitted a reversal; thus the second signal would be three times as long as the first—the proper respective lengths of a dot and a dash—and so on with the other signals and spaces.

The *Receiver*, by means of which the signals sent by the transmitter are recorded, is a direct ink-writer of a very sensitive character. The slip is drawn forward between two rollers by means of a train of wheels driven by a large weight. Before passing between the rollers the slip is brought near to a small inking disc which is rotated when the clockwork is in motion. The instrument is regulated by a fly to maintain uniform speed, and this fly is so arranged that by means of a lever the speed of slip can be adjusted to suit recording at any speed between 20 and 450 words per minute. The light marking disc is fixed to an axle geared with the clockwork, and rotates close to the periphery of a larger disc that moves, in the reverse direction, in a well of ink. This latter disc takes up the ink and feeds the marking disc by capillary attraction without introducing friction.

Passing now to the electrical arrangement of the receiver, the electro-magnets which work the recording armature consist of two bobbins of fine silk-covered copper-wire, having cores of carefully annealed soft iron. If these cores were provided with a cross-piece they would form what is generally known as a horseshoe-shaped electro-magnet; but less electro-magnetic inertia and greater rapidity of action are obtained by dispensing with the cross-piece and providing a second armature at the lower end of the axle, polarised in the opposite direction to the upper armature by means of the other pole of the inducing magnet. The arrangement is, in fact, similar to that shown by fig. 4. The *working* speed at present attained by this system is about 400 words per minute, although it has been possible to greatly exceed this speed in experimental running, and the *workshop test* is a speed of 450 words. An English telegraphic 'word' is taken to be twenty-four possible reversals on the transmitter.

(11) *News Circuits.*—Automatic instruments are employed on nearly all long circuits in England, not only because they increase the capacity of the wires for the conveyance of messages, but because they are so specially adapted for the conveyance of news, which is such a distinctive feature of the English system of telegraphy. One batch of news is often sent to a great many different places, and as four or even eight slips can be prepared at one operation, and one slip can be used several times, the labour of preparing for transmission is very much reduced. In fact, without this system it would be simply impossible to transmit the enormous amount of intelligence sent telegraphically all over the country. There are many news circuits radiating from the Central Telegraph Station,

having three and four intermediate stations upon them, one or more of which 'repeat' or 'translate' onward to three or four more stations. Thus one punched slip disseminates the news to many places.

As already stated, the transmission of 'news' for the metropolitan and provincial press constitutes a special and distinctive feature of the English system. The work involved is enormous. During the year ending the 31st March 1891 5,003,409 press telegrams, containing no less than 600,409,000 words, were transmitted through the Postal Telegraph Department—an average of nearly two million words per diem. The press tariff, however, is arranged on so low a scale that the average price paid is only a little over 2d. per hundred words. During ten years the increase in news transmitted was about 83 per cent.; the numbers for the year ending 31st March 1881 having been 2,735,042 messages and 327,707,407 words. Messages can be sent at the press rate only after 6 P.M. To save delay and secure the transmission of their news at a fixed cost and without the inconvenience of keeping and checking telegraph accounts, several journals arrange for the sole use of a wire during certain hours of the evening. Thus, six Scottish journals appropriate nine London wires after 6 P.M.; four wires are allotted to as many Irish papers, while dailies published in English provincial towns absorb sixteen more. Some of the London dailies have a wire to Paris every evening, and one (the *Daily News*) also has one to Berlin.

Turning now to the news transmitted by the departmental operators, a large proportion is of general interest handed in by various news agencies. Such news items have to be sent to addresses in all parts of the country, and to effect this the slip once prepared can be used over and over again upon different circuits; moreover, by means of pneumatic power, the perforators at the Central Telegraph Office are capable of punching as many as four slips at a time, and, the pneumatic instruments being arranged to work two perforators, *eight* slips are thus prepared at one operation. Not only can one slip be used upon several different circuits, but often several offices which generally take the same class of news can be placed upon one circuit, so that all take the same messages simultaneously. On the other hand, in some cases when an address is outside the delivery of a news circuit the message has to be received, written up, and again transmitted. Indeed, in some cases this has to be done twice for some small towns which publish weekly or bi-weekly papers, and the second transmission may even have to be done by hand.

(12) *Repeaters.*—The length and description of a circuit has a great deal to do with the possible speed at which it can be worked. The greater the distance, as a rule, the lower the speed, and the reducing effect of a mile of underground wire is greater than 20 miles of aerial line. But even with an aerial line the leakage, &c. at the insulators makes the strength of current received, as compared with that sent out, proportionally less as the distance increases; and although it is of course possible to compensate for this loss by an increase of battery power, it is not so easy to compensate for the retardation due to electrostatic capacity. In dry climates the limit of distance for uninterrupted communication is rarely reached in practice, but in England the conditions are such that 400 miles may be taken as the limit. It then becomes necessary to take off the messages and repeat them by clerks, or to introduce a *repeater* or *translator* which, worked by the original currents, will automatically transmit or relay stronger currents similar in direction to, and of equal duration with, those which are passed through it. It is, in fact, an extension of the principle of the ordinary relay, and is introduced into the circuit for a similar reason—the relay is placed in circuit that it may be actuated by currents which would not work the sounder or Morse writer direct, and completes a local circuit in which the receiving apparatus is placed; the repeater is also arranged to relay similar currents to those which actuate it; but while the relay as ordinarily used is required to work an instrument in the same office, the prime function of the repeater is to retransmit the signals along an extension of the original line. By this means it is possible to work to any distance. Thus the Indo-European line from London to Teheran, a distance of 3800 miles, is worked directly (without any retransmission by hand) by means of five repeaters.

Varley introduced repeaters at Amsterdam to translate the English double-current system of working into the Continental single-current system in 1858, but in England the Post-office has introduced them to increase the rate of working. There is, however, a limit to the number of repeaters which can be employed on one line. The motion, friction, and inertia, both magnetic and mechanical, of the moving parts, and the introduction of disturbing electrical causes, prevent the duration of the contact of the tongue of the relay from being the exact counterpart of that of the sending key. It is of less duration. Retardation therefore takes place, and the rate of working is reduced with each relay added. In few cases in England is more than one repeater introduced, but by means of that an actual and decided increase of speed is obtained, due to the fact that the speed of working of the whole circuit is made that of its worst section alone. Their value may perhaps be best demonstrated by stating that by means of the *Fast Duplex Repeater* it is possible to mechanically retransmit messages, at the rate of 450 words per minute, simultaneously in both directions, on circuits exceeding 400 miles in length; and by referring to the fact that the highest speed attainable without repeater upon the London-Amsterdam wire is 116 as compared with a speed of 400 words with a repeater at Lowestoft, while the London-Dublin circuit without repeater will give only 120 words, and with a repeater at Nevin a possible 450. The latter figure, too, represents the highest possible speed not of the line but of the present form of instrument. It is impossible, however, in this article to give a correct idea of the working details of the repeaters now used.

(13) *Submarine Telegraphy.*—Owing to the retarding influence of a long submarine cable, by which it becomes difficult to pass ordinary electric currents through the cable except at very long intervals, giving the cable meanwhile time to discharge, and owing also to other disturbing causes, special means have to be adopted in working such cables in order to obtain the maximum possible speed. The method usually adopted was invented by C. F. Varley, and consists in interposing a condenser in the receiving circuit, so that instead of the circuit being complete it is interrupted at the condenser; and the instrument—a very sensitive form of galvanometer devised by Lord Kelvin (Sir William Thomson)—is actuated merely by the charge and discharge of the condenser. The Thomson galvanometer, without which long cables could scarcely have been commercially successful, consists essentially of a magnet composed of one or more pieces of watch-spring, ⅛-inch in length, cemented upon a small circular convex mirror of silvered glass, which is suspended by a short thread of cocoon silk without torsion. This needle is suspended in the centre of a coil of very fine wire, and a ray of light is projected from a lamp upon

the mirror. The beam of light is reflected at some distance upon a scale, and a very minute movement of the mirror therefore produces a considerable movement of the ray projected upon the scale. The movements of the spot of light upon the scale are read off in precisely the same way as the motions of the pointer on the dial of a single-needle instrument. The ordinary Morse system on an Atlantic cable could scarcely have a speed of one word a minute, while fifteen words is a usual speed with the reflecting galvanometer, and twenty-four have been obtained. Lord Kelvin also invented in 1867 the *Syphon Recorder*, by which cable messages can be permanently recorded as on the Morse system; this is now superseding the mirror instrument. For short cables, special applications of the ordinary systems are adopted.

Submarine cables are generally made each on its own merits or according to the experience of the consulting electrician. The deep-sea portion of an Atlantic cable laid in 1865, shown in fig. 12, was formed thus: Seven copper wires were laid up together, six being laid spirally around the seventh, and so thoroughly surrounded with Chatterton's compound (a mixture of resin, Stockholm tar, and gutta-percha) that every interstice was filled. Over this were laid alternately four coatings of compound and of pure gutta-percha. This was then carefully wrapped with jute and the whole was sheathed with ten iron wires, each of which was first completely wrapped with strands of tarred Manilla yarn. The total diameter was 1·127″; the weight per knot in air, 36 cwt.; and its breaking strain, 8 tons. 'Shore end' cable is always further protected with an additional plain wire sheathing over an extra thickness of hemp.

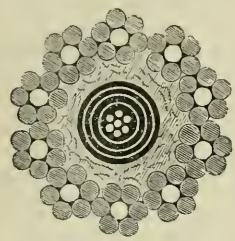

Fig. 12.

(14) *Wireless Telegraphy.*—The possibility of directing electric currents wholly or partly without wires has occupied the attention of electricians, more or less successfully, for many years. Marconi, an Italian electrician, patented in 1897 an electrostatic method entirely independent of wires, by means of which, in March 1899, he conducted a most exhaustive series of successful experiments, sending messages across the English Channel from the South Foreland to the French coast near Boulogne. Further successful experiments were made at sea in November 1900, and the Admiralty have definitely adopted the system. The Trinity House propose to apply it to lighthouses and lightships.

Marconi's system is based on the property the vibrations or waves of electric currents passing through a wire possess, of setting up similar vibrations in the ether which fills all space. These waves vibrate in every direction; and by ingenious and very delicate receiving instruments Marconi gathers them up in sufficient strength to repeat their pulsations and record their messages from the transmitter. As the height at which the transmitting and receiving wires are placed above the earth materially affects the distance to which messages may be sent, Marconi erects poles for this purpose at his stations, suitable for the distance required. In 1900, having discovered how to modify this principle by controlling the air waves without the necessity of very high masts, Marconi was confident of being able to communicate across the Atlantic. The state of the weather does not affect it in any way.

III. *Statistics.*—The first public telegraph company in England—the Electric and International—was founded in 1846. This was followed by the British and Irish Magnetic, the United Kingdom, and many others, besides which the various railway companies transmitted messages upon their own systems, and acted as agents to the various companies. This arrangement continued, greatly to the public inconvenience, until 1st February 1870, when, by an Act of 1869, the property of the companies was transferred to the state at a cost of £10,880,571, and a monopoly of telegraph business was vested in the Post-office Department.

The first telegraph company in the United States—Washington to New York—dates from 1845. In 1890 the telegraphs of the United States were almost all in the hands of the Western Union Company. International rates, regulations, &c. have all been settled at telegraph conventions. Hitherto submarine telegraphs have been mainly in the hands of the English-speaking race. Of some 300 cables owned by private companies all but twenty are held by English-speaking people. The Eastern Telegraph Company serves southern Europe, Egypt, Bombay, &c., and connects with South African, Australasian, and Chinese cables. In 1899 the British government agreed with Canada and the Australasian colonies to subsidise an all-British Pacific cable, from Vancouver by Fanning Island and Fiji to Norfolk Island, whence branches diverge to Australia and to New Zealand.

Of the fifteen cables crossing the Atlantic in 1899, three were 'dead,' nine were in perfect condition, and three were useful for simplex working. In 1869 the Anglo-American Telegraph Company laid 2717 miles between Brest and St Pierre, the longest continuous length; and afterwards three other transatlantic cables, their system extending to 10,400 miles. The Western Union Company laid two cables in 1881–82; and the Commercial Cable Company two in 1884, which led to a reduction in rates from 2s. to 1s. per word.

In 1900 estimates (£1,795,000) for an All-British Pacific Cable were accepted by a committee representing Britain, Canada, Australia, and New Zealand, to be finished in 1902. The cable will run from Vancouver to New Zealand *viâ* Fiji and Norfolk Islands.

The transatlantic tariff of the Western Union Telegraph Company, which may be taken as representative of the other companies, is 1s. per word for messages to be delivered in New York City, Brooklyn, and Yonkers, and 1s. 2d. per word for other places in the state of New York. The 1s. rate applies also to Ontario, Quebec, Cape Breton, Connecticut, Maine, Massachusetts, New Brunswick, Newfoundland, Nova Scotia, and a few other places. The highest rate to the States or to Canada is 1s. 6d., which applies to British Columbia, North-west Territory, and Vancouver Island.

Bright, *Submarine Telegraphy* (1898); Preece, *Signalling through Space without Wires*, Royal Institution Discourse, 4th June 1897.

Telegraph Plant (*Desmodium gyrans*), an Indian leguminous plant. Of its trifoliate leaves the lateral leaflets, which are small, have, especially in a warm, moist atmosphere, a strange spontaneous motion; they jerk up and down (sometimes 180 times in a minute), as if signalling,

and also rotate on their axes (see PLANTS, Vol. VIII. pp. 221, 222).

Tel-el-Amarna, or TELL-EL-AMÂRNA, the modern name of a mass of ruins representing the capital of the heretic Egyptian king, Amenhotep IV. (see EGYPT, Vol. IV. p. 240), a little to the north of Assiout, on the eastern bank of the Nile. Here was found in 1887 a collection of tablets in Babylonian cuneiform, at that period—some time before the exodus of the Israelites out of Egypt—used as a kind of *lingua franca* for all western Asia. These tablets were mainly reports from the Egyptian governors of Palestine, Syria, Mesopotamia, and Babylonia, some of which implored help against the Hittites (q.v.), then pressing southwards. Of about 230 tablets 160 went to the Berlin Museum and 82 to the British Museum.

Tel-el-kebir, midway on the railway between Ismailia and Cairo, was the scene on the morning of 13th September 1882 of the capture by Sir Garnet Wolseley of Arabi Pasha's entrenched camp, defended by 26,000 men. The British loss was about 430 killed and wounded, the Egyptians' 1500.

Tele'machus, son of Ulysses (q.v.) and Penelope, was an infant when his father left home to join in the war against Troy, but during his twenty years' absence grew into manhood. Under the guidance of Athene, who had assumed the appearance of Mentor (q.v.), Telemachus set out in search of his long-lost sire, after having vainly endeavoured to eject his mother's troublesome suitors from the house. Having visited Pylos and Sparta, Telemachus returned home to Ithaca, where he found his father in the guise of a beggar, and with him proceeded to slay the suitors.—In modern times Telemachus is known chiefly as the hero of Fénelon's romance, once very popular as a school-book.

Teleology (Gr. *telos*, 'an end'), the doctrine of final causes (see CAUSALITY), is usually limited to the argument for a creator and for the existence of God derived from the existence, beauty, and perfection of the world; the *a posteriori* argument of Apologetics (q.v.). See also THEISM.

Teleosaurus, a genus of fossil crocodiles, the remains of which occur in the Lower Jurassic rocks. They are found associated with marine fossils, and the peculiar modification of their skeleton seems to have specially fitted them for an aquatic life. Both surfaces of the vertebræ were slightly concave, the hind-legs were large and strong, and the anterior portion of the body gradually tapered into the long and slender jaws, giving the animal the aspect of the gavial of the Ganges; but the jaws were more attenuated, and the nasal aperture, instead of being oblique, opened vertically on the truncated end of the upper mandible. The jaws were armed with numerous equal and slender teeth, slightly recurved.

Teleostei. See BONY FISHES.

Telepathy, a word coined about 1886 from the Greek to express the supposed power of communication between one mind and another by means unknown to the ordinary sense-organs. Some members of the Psychical Research Society believe that they have established the fact that such a power does exist in the material universe, and have attempted to turn the assumption to account in the explanation of certain unexplained natural phenomena. See the Society's *Proceedings*, and Gurney and Myers, *Phantasms of the Living* (1886).

Telephone. This instrument is designed to reproduce sounds at a distance by means of electricity. Sound is due to vibrations of the air, and these vibrations differ among themselves in, and are characterised by, three particulars—viz. frequency or number per second, amplitude or range of displacement, and co-existence of simultaneous vibrations affecting the same air. These physical data determine respectively the pitch, the loudness, and the character, quality, or *timbre* of a sound. The mechanical problem of telephony then is, given an air-vibration which presents these three characteristics in any determinate way, to reproduce a similar air-vibration at a distance; then this, being received by the ear, will be perceived as sound. Under the most complex vibration no particle of air can be in more than one place at once: hence the net result of superposition of the most complex possible series of vibrations, from single melody or smooth harmony to the most complicated noise or the most delicate inflexion of the human voice, is a movement of each air-particle which may be represented by a curve of an apparently irregular form, lying alternately above and below a straight line which threads the curve and represents the position of the air-particle when undisturbed. The reproduction of this irregular resultant motion is the most general form of the problem: the earliest attempts were confined to the reproduction of the frequency of a vibration—i.e. the pitch of a sound, the first of the particulars above mentioned. In 1860 Reis of Frankfort first attacked the problem: he used a collodion membrane, upon which the sound-waves produced by the voice were made to impinge; this membrane, vibrating under their influence, alternately displaced and liberated a lever, which alternately made and broke the circuit of a galvanic battery; the intermittent current thus produced acted upon a distant electro-magnet which alternately attracted and failed to attract its armature; the armature thus oscillated, and a wing or plate attached to it acted upon the air, which was thus set in vibration, reproducing the pitch of the original tone or the inflection of the original voice. It appears from recent inquiry that Reis actually did more than this; but the next step is attributed to Mr Elisha Gray of Chicago, who sent successions of electrical current of varying strength as well as of varying frequency into the circuit, and thus enabled the relative loudness as well as the pitch of sounds to be transmitted; and who afterwards took the important step of using the variations of a steady current. These variations, positive and negative, are capable of representing all the back-and-fore variations of position of a particle of air, however irregular these may be: and he secured them by making the sound-waves set a diaphragm in vibration; this diaphragm carried a metallic point which dipped in dilute sulphuric acid; the deeper it dipped the less was the resistance to a current passing through the acid, and *vice versâ*: so that every variation in the position of the diaphragm produced a corresponding variation in the intensity of the current: and the varying current acted upon a distant electro-magnet, which accordingly fluctuated in strength, and in its attraction for a piece of soft iron suspended on a flexible diaphragm: this piece of soft iron accordingly oscillated, pulling the flexible diaphragm with it; and the variations of pressure in the air acted upon by the diaphragm produced waves, reproducing the characteristics of the original sound-waves, and perceived by the ear as reproducing the original sound or voice. Mr Gray lodged a *caveat* for this contrivance in the United States Patent Office on 14th February 1876; but on the same day Professor Alexander Graham Bell filed a specification and drawings of the original Bell telephone. In this the flexible diaphragm upon which the sound-waves impinge bore a small bar-magnet, which was thus made to oscillate; it oscillated in the immediate neighbourhood of the pole of an electro-magnet round which passed the continuous current of a battery;

the oscillation of the bar-magnet in the neighbourhood of the pole caused fluctuations in the strength of the electro-magnet; these fluctuations caused variations in the intensity of the current passing continuously round the electro-magnet, and away to the distant receiver; there the varying current found an electro-magnet to act upon, and this exerted varying tension upon a soft-iron diaphragm. Later on Bell disclaimed the use of a non-metallic flexible diaphragm in the transmitter, and used only a soft-iron diaphragm; and he also used a permanent magnet instead of an electro-magnet in that instrument, it being found that currents of sufficient intensity were produced thereby. He also used similar instruments at both ends of the line. For these two later modifications priority is claimed on behalf of Professor Dolbear. Mr Edison secured the requisite variations of the current in another way. He found that lamp-black and certain other substances could be prepared in masses which were slightly compressible, resilient, and semi-conductive, and which varied in conductivity as they became exposed to greater or smaller pressures; and that the variations in conductivity were very satisfactorily proportional to the variations of pressure. The vibrations of the diaphragm were accordingly made by him to concentrate themselves upon a small button of such a substance, and thus to induce variations in the conductivity of the circuit.

At the present time instruments of the Bell telephone type are mainly used as receivers only. In the Bell receiver itself both poles of the magnet are now brought into proximity to the magnet; and the instrument may be flattened down into the form of a watch. In the Gower receiver the form is also watch-shaped, and the sound is conveyed to the ear by tubes. In the Ader receiver the electro-magnetic field acting upon the ferrotype iron diaphragm is improved, being rendered more intense and more uniform by a ring of soft iron placed outside the diaphragm. In other receivers devices are applied for economising wire, for decreasing the magnetic resistance of the magnetic circuit, for facilitating construction and regulation, &c. The transmitter is now almost always some modification of the Microphone (q.v.). Edison's instrument, above described, is in substance a microphone; it is, however, not operated by shaking the whole apparatus as in the original Hughes microphone, but by bringing variations of pressure to bear upon the carbon button. In the Blake transmitter the same principle is applied; the current of a battery passes through the button, and is there made to vary, and it also passes through the primary winding of an induction coil: the variations are taken cognisance of by the secondary winding which transmits them, adequately intensified, to the general circuit. The Crossley, the Gower, and the Ader transmitters are more obviously adaptations of the Hughes microphone, with eight, sixteen, and twenty loose contacts respectively instead of two, and attached to the under side of the vibrating diaphragm, which in the Gower and the Crossley is a thin sheet of wood. Other types are the Johnson, which is provided with a shunt so as to adjust the current transmitted, and thus prevent buzzing; the Hunnings, in which powdered coke is used; the Swinton, which depends on swinging carbon rods resting by loose contacts against a carbon bar, there being thus no diaphragm in the popular sense, though the English courts have decided that the carbon rods are mechanically equivalent to a diaphragm; and Thompson's valve transmitter, in which a ball of carbon rested upon three carbon buttons and was impinged upon by air-waves from beneath.

The word 'telephone' is now usually applied to the complete instrument, comprising the transmitter, the receiver, and the various subsidiary appliances, such as switch bells worked by a battery or by a small magneto-electric machine, driven by a crank for signalling purposes. The arrangements which have to be devised for the purposes of a central telephone station increase rapidly in complexity with the number of subscribers. For these, and for the means adopted to minimise the effects of induction from neighbouring wires, &c., the reader may consult Allsop's *Telephones* (1891); Preece and Maier, *The Telephone* (1889); and Preece's *Manual of Telephony* (1893).

Of the five leading telephone patents for Great Britain, the last, the Crossley transmitter, was to expire 1st February 1893. In 1880 (21st December) Mr Justice Stephen decided in favour of the British Post-office that telephony was a form of telegraphy. Since that decision telephony has been carried on in Britain under the Postmaster-general's license, on payment of one-tenth of the gross receipts. In 1891 this tenth amounted to £40,000, in 1898 to £100,000. France, Germany, Austria, and the Continent generally are well supplied with trunk lines; and in England most of the chief towns are connected directly with London, and there is an increasing number of other lines. The first London-Paris line was opened in March 1891. In Berlin the system of laying wires underground was very thoroughly developed. On the Continent the telephone is largely used by the rural post-offices; and in France any person may telephone from a call-office to a post-office, and his verbal message will be transcribed and sent on as a telegram. In the United States the microphonic transmitter patent only began to run its course of seventeen years in 1891, on account of a dispute as to priority between Edison and Berliner. In the United States the telephone is very extensively employed, and the distances run are great, up to 1000 miles, with specially thick wire.

In 1892 the Telegraphic Act gave the Post-office entire control of the trunk wires throughout the kingdom. The intention was to provide a complete system of telephonic communication between the important towns, leaving the towns themselves to be dealt with by individual companies. The National Telephone Company, using mostly Blake transmitters and Bell receivers, gradually absorbed the other companies, obtaining a practical monopoly of the work; and it secured a license from the Postmaster-general, which expires in 1911. In 1898 it had 918 exchanges and 1424 call-offices in the United Kingdom. Dissatisfaction having been expressed as to the imperfect service of the National Company, the government in 1898 appointed a select committee, which reported that no system can be satisfactory which is worked under a practical monopoly by a private company for private profit, and that the work should be carried on like the Post-office, for the benefit of the whole country, and not only certain localities and limited areas. They recommended general competition, either by the Post-office or by municipalities acting under license, but favoured the former as promising a more general benefit. The proposed legislation on these lines (1899), to give facilities for extending municipal licenses, was opposed on the ground that the only proper remedy is for the Post-office to take over the whole work at once.

Telerpeton, a remarkable genus of fossil reptiles, the relics of which have been found in fine-grained whitish sandstone of Triassic age quarried at Cummingston, near Elgin. A single species, or rather a single specimen, is all that as yet has been detected. It exhibits the skeleton complete, with the exception of the termination of the tail, but the bones have disappeared, and left

only the casts as dark-coloured cavities in the pale-gray rock. Nearly perfect casts of their forms were taken by Dr G. Mantell from these hollow casts. The impressions are so well defined as clearly to show that there were twenty-six vertebræ between the skull and the sacrum, two sacral vertebræ, and the portion of the tail preserved on the slab consists of thirteen others. The ribs, of which there are twenty-one pairs, are very slender; they are short near the head, but quickly lengthen as they leave it. The reptilian nature of this fossil is evident. By Dr Mantell it was considered to be a batrachian, and described as *Telerpeton Elginense;* but Professor Owen has more correctly referred it to the lacertine type, because of the numerous ribs, the structure of the sacrum, and the form of the pelvis.

Telescope (Gr. *tēle-skopos*, 'far-seeing') usually consists essentially of a lens or mirror, to form within our reach a real image of a distant object suspended in space; and a Microscope (q.v.), to examine this image in detail. Anticipations of the telescope have been claimed for Roger Bacon (died 1294?); and Sir Richard Burton alleges that long ere this it was known to the Arabian scientists (see the supplement to his *Arabian Nights*). Leonard Digges, an English mathematician, very suggestively describes in his *Geometricall Practise* (1571) 'the marvellous conclusions that may be performed by glasses concave and convex, of circular and parabolic forms,' speaks of a separate volume (never published) describing 'the miraculous effects of perspective glasses,' and must be held to have at least anticipated the invention. Della Porta (died 1615) may have made a rude telescope. But the telescope from which all later ones proceed by lineal descent seems to be that presented to the General States of Holland on 2d October 1608 by the optician Hans Lippersheim or Lippershey of Middelburg—though possibly another optician, Zacharias Jansen, and the mathematician Adriaan Metius had also something to do with the development of this same telescope. The value of the invention was immediately realised; telescopes were being sold in Paris next year; and Galileo, hearing of the Dutchman's invention, made a telescope for himself, with which, the first night he used it (7th January 1610), he discovered three of Jupiter's moons. Kepler (1611) is the inventor of the astronomical telescope.

The way in which an inverted real image is formed by a lens is described under LENSES; see also MIRROR. The reason why it is necessary in a telescope to produce a real image which may itself be subjected to examination by means of a lens is the following: If a single magnifying lens, or an equivalent combination of lenses, be placed between a distant object and the eye, the image formed will not be thrown upon the retina itself, and nothing will be distinctly seen, unless indeed the eye is taken far enough back to see the minute real image itself. If, on the other hand, a real image be projected in space within our reach, a magnifying lens or combination of lenses can be made to examine that image as if it were an object, after the fashion of the Microscope (q.v.). If the eyepiece be equivalent to a single magnifying lens or simple microscope, the inverted real image will not appear to be re-inverted, and then what the eye sees on looking through the combination is an inverted magnified representation of the distant object, as in the astronomical *refracting* telescope; but if it be equivalent to a compound microscope, it will appear to re-invert the inverted real image under examination, and will thus furnish an uninverted representation of the object, as in the terrestrial telescope. The astronomical form is thus simpler than the terrestrial, and absorbs less light; and it is accordingly used for sailors' night-glasses. If the real image be formed by a concave mirror, a plane reflecting surface or secondary mirror may be interposed so as to turn back or turn aside the reflected rays before they have actually formed the real image, and thus to cause the real image to be produced in some place where it can conveniently be examined by a magnifying eyepiece. If the reflected rays be turned aside through 90° by a plane reflecting surface, the magnifying eyepiece will be at the side of the instrument; and then we have the Newtonian

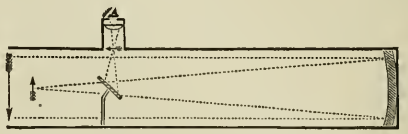

Fig. 1.—The Newtonian Telescope.

form of the astronomical *reflecting* telescope (fig. 1), exemplified by Lord Rosse's telescope. If the reflected rays be simply sent back along the axis of the instrument, they—or the central portion of them—may be allowed to pass through a small hole in the centre of the concave mirror, and dealt with by an eyepiece on the other side of that mirror; in which case we have the Gregorian form of the reflecting telescope (fig. 2), where the eyepiece is at

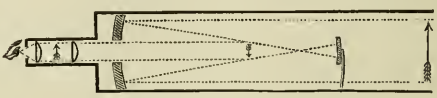

Fig. 2.—The Gregorian Telescope.

the end, as in the ordinary terrestrial telescope. If the concave mirror be tilted slightly to one side it will, without loss of light due to the intervention of a second mirror, itself bring the real image towards one side of the apparatus. There it may be examined by means of an eyepiece suitably placed, directed obliquely towards the mirror; and this is the Herschelian form of the instrument (fig. 3).

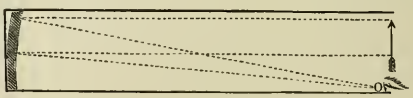

Fig. 3.—The Herschelian Telescope.

These are the three main forms of the reflecting telescope; they are subject to minor modifications, for which see works on practical astronomy.

A telescope cannot be made of invariable length, for two reasons. In the first place, for a given eye there is a fixed, most suitable distance between the eyepiece and the proper position of the real image to be examined by it. Wherever the real image happens to be formed, the eyepiece, simple or compound, must be moved into the proper relative position with regard to that real image; but the image of a nearer object is formed farther from a lens or from a concave mirror than is the image of a more distant object, for which reason the eyepiece of a telescope must be moved farther away from the objective or reflector in order to examine the image of a nearer object; and the telescope as a whole must be lengthened for nearer, or shortened for more distant objects. In the second place, the eyes of different observers may not be similar; each observer may have his own proper fixed distance between the eyepiece and

the real image, according to his long-sightedness, short-sightedness, or normal vision. Consequently the distance traversed by the rays between the objective or mirror and the eyepiece is always made adjustable by sliding tubes or otherwise.

When a telescope is in 'focus' a pair of cross-fibres, placed in the focus of the eyepiece, will appear to retain a fixed position with regard to any point of the object as seen through the telescope, even though the eye of the observer be moved up and down or from side to side. This is called the parallastic method of focussing. By substituting for a given eyepiece others of different magnifying powers, the magnifying power of a telescope as a whole may be varied. The magnifying power of a telescope is the ratio between the focal length of the objective and that of the eyepiece. For suppose an object, say a chimney-stalk, 100 feet high at 10,000 feet distance, and the telescope directed towards the bottom of it, the angle subtended by the object, from the point of view of the objective-lens, at the crossing-point of the rays from the top and the bottom of the chimney-stalk, will be a little over 34′, an angle whose tangent is $\frac{1}{1\frac{1}{0}\frac{0}{0}\frac{0}{0}}$. If the objective could be supposed to look backwards and to see the real image produced by it in the body of the telescope, that image would again subtend an angle of 34′, and there would not be any magnification, for the visual angle subtended would be the same. If the image were produced at 1 foot from the crossing-point of the rays, it would have an actual length of $\frac{1}{1\frac{1}{0}\frac{0}{0}}$ foot or $\frac{3}{2\frac{5}{0}}$ inch. But after passing through the eyepiece the rays from the virtual image of the whole object would tend to enter the eye of the observer at the same visual angle as the rays from the top and the bottom of the real image of the chimney would cross one another in their transit through the eyepiece if it were a real object there situated; and so we may look at the matter as if that crossing-point in the eyepiece were itself the organ of vision. From that point the real image of the size mentioned at say $\frac{1}{2}$ inch distance would subtend an angle of 13° 30′, or an angle whose tangent is $\frac{2\frac{4}{0}\frac{0}{0}}{1\frac{0}{0}\frac{0}{0}\frac{0}{0}}$, or twenty-four times the preceding. But the apparent size is proportional to the tangent of the visual angle measured with reference to the axis of the system; hence the magnification here is as 24 to 1, or as 1 foot (the focal distance between the real image and the objective) is to $\frac{1}{2}$ inch (that between the real image and the eyepiece). If in this last case the aperture of the object-glass had been the same as that of the pupil of the eye, the magnification would not have been affected; but there would have been a lack of illumination, because an equal amount of light from the same source would have been made to produce on the retina an image about twenty-four times as large linearly, or 576 times superficially.

If, however, in the case supposed, the objective be twenty-four times as great in diameter as the pupil of the eye, this is—apart from loss of light by absorption in the lenses—compensated for, and the illumination is restored. With lenses of larger diameter than is necessary to compensate the loss of illumination by magnification, the field appears brightly lit. Where there is no loss of illumination through magnification, as in the case of stars, which are too far to be magnified into appreciable discs, the increase of brightness in the objects viewed enables objects to be seen which make no impression upon the naked eye. Suppose a star to be so far as to be visible and no more; then another equal star, ten times as far, would appear to shine, under the law of inverse squares (see LIGHT), with one-hundredth the intensity of the former, and would be invisible to the eye; but if its light were collected over an area a hundred times as great as that of the pupil, and sent into the eye, the eye would again be just enabled to perceive it; and in order to secure this hundred-fold area the diameter of the objective must be ten times that of the pupil of the eye. The space-penetrating power of a telescope is therefore—assuming that there is no loss of light in the telescope itself, which is not the case—directly proportional to the diameter of the objective.

The Opera-glass (q.v.) is often described as a form of telescope under the name of Galileo's telescope; and, while it does not magnify greatly, it is very serviceable in collecting much light and brightening the field. Mr Francis Galton says (*Vacation Tours in South Africa*, chap. ix.) that a large opera-glass is 'one of the most perfect of night-glasses, besides being the most useful of telescopes.'

As to the unavoidable imperfections of the telescope, we find in the first place that even with a mirror, as in a reflecting telescope, where we are not annoyed by the breaking up of white light into its component colours, since the Law of Reflection (q.v.) is the same for all rays, it is impossible to form a perfectly sharp image of more than *one* definite point at a time. In order to do even this the mirror must be formed as part of the prolate spheroid produced by the rotation, about its longer axis, of an Ellipse (q.v.), one of whose foci is the object-point, the other the image. If the object-point be, like a star, practically at an infinite distance, the requisite form of the mirror is that formed by the rotation of a Parabola (q.v.) about its axis. The axis of the mirror must then be directed to the object-point, and all rays from it will, after reflection, pass accurately through the focus. But this is not strictly true for any other object-point in the field of view, although it is so nearly true that no inconvenience is practically found to result. But if the mirror used be part of a sphere, no point can be found such that rays diverging from it shall all be brought after reflection accurately to one point of the image; and this defect, called *Spherical Aberration*, increases with the surface of the mirror of any given radius; so that by increasing that surface, for the attainment of brightness, we increase proportionally the indistinctness of the image. To give an idea of the delicate manipulation required in the construction of a reflecting telescope we take the case of a speculum of 4 feet aperture and 40 feet focus, as calculated by Sir J. Herschel. If this be first ground to a truly spherical form it must have a radius of 80 feet. Now, such a mirror will give a very indistinct image, even under the most favourable circumstances; yet to grind it to the parabolic form, which is practically perfect, leaving the middle untouched, and grinding more and more away from its surface as we proceed outwards to the edges, even at the edges we have to remove a film of metal of only the $\frac{1}{2\frac{1}{3}\frac{1}{3}\frac{1}{3}}$d part of an inch, somewhere about the $\frac{1}{1\frac{1}{0}\frac{0}{0}}$th part of the thickness of the paper on which this is printed! The spherical aberration is partly compensated in Cassegrain's modification of Gregory's telescope, in which the small secondary mirror is convex.

Lenses, whether the object-lens or the eye-lens, have this defect also; but, as a rule, the most conspicuous fault of single lenses is their *Chromatic Aberration*, which arises from the different refrangibilities (see REFRACTION) of the various coloured rays, and leads to the formation, by a lens, of separate overlapping images of a bright object for each coloured ray. The remedy consists in *achromatising* (see ACHROMATISM, REFRACTION) the lens—i.e. forming it of two or more lenses of different kinds of glass, so that the colours, separated by one, shall be reunited by the others.

The curvatures of the lenses which make up the achromatic combination, and the distances between them, may be so chosen as to minimise the effects of spherical as well as of chromatic aberration. Galileo's telescope has less chromatic and spherical aberration than the common astronomical telescope, and is shorter, since the distance between the lenses is approximately the *difference*, not the *sum*, of their focal lengths.

Before the discovery of the possibility of forming an achromatic lens Huygens, Cassini, and others had endeavoured, by enormously increasing the focal length of the object-glass of the common astronomical telescope in proportion to its diameter, to get rid as far as possible of chromatic aberration.

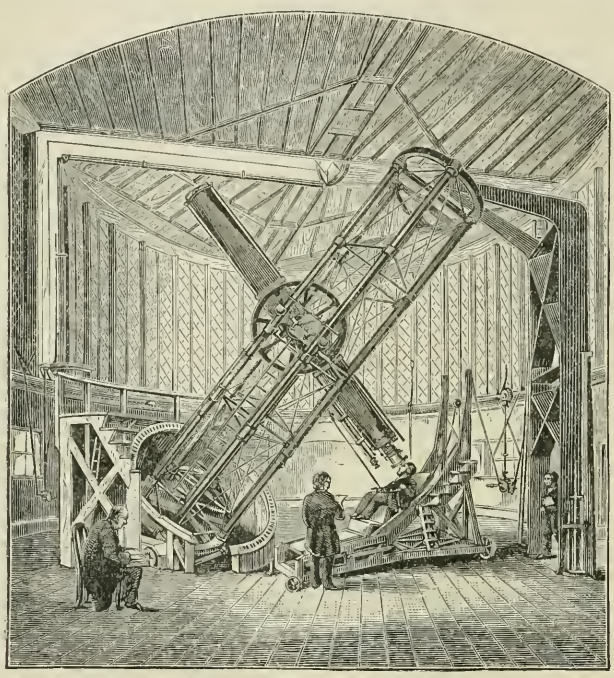

Fig. 4.—The Great Equatorial Telescope at Greenwich Observatory (from Dunkin's *The Midnight Sky*).

They thus formed the *aërial* telescope, in which the object and eye lenses were mounted separately on stands; the tube (which would have been 100, 200, or even 600 feet long) being dispensed with. Valuable work was done with some of these telescopes, of 125 feet focus, but the longer ones proved unmanageable. The principle involved in these constructions is, practically, the throwing the magnifying power more on the object-lens than on the eye-lens; for the image formed by the former was still so imperfect as not to bear much additional magnification. The great step required for shortening the unwieldy instrument was therefore the perfecting of the object-lens, by achromatisation. Various very ingenious improvements on achromatic combinations, which might even yet be thought worthy the consideration of opticians, were devised by Dr Blair. He found solutions of mercury or antimony in hydrochloric acid to be much more refractive and more dispersive than crown-glass, while no irrationality of dispersion as compared with crown-glass could be detected in them. By means of lenses filled with these liquids he was enabled to give the telescope an aperture of one-third of its focal length without a trace of residual colour.

The process of Liebig for depositing on glass an exceedingly thin film of silver, which, by careful polishing, can be rendered more highly reflective than any other material, has been taken advantage of by Steinheil in the construction of large specula for reflecting telescopes. This is an immense step, since any disc of glass will do, its optical properties not being employed; while, if it be once brought to a true parabolic figure, the silvering may be renewed as often as may be required. One of the great difficulties in the construction and working of large reflectors has hitherto been the casting and annealing of metallic masses of some tons weight. This, in the silvered specula, is entirely avoided. We cannot here enter into a description of the processes, often extremely ingenious, which have been devised for the grinding, figuring, and polishing of lenses and specula.

Amongst the largest reflecting telescopes are those of Lord Rosse at Birr (72 inches aperture, 1844), Mr Commons, at London (1889, 60 inches), Bessemer (50¾ inches), Sir William Herschel (48 inches, 1789, long since dismantled), Melbourne (48 inches), Paris Observatory (47 inches). To the largest refracting telescopes belong those of Yerkes Observatory, Chicago (41½ inches, 1897), Lick Observatory, California (36 inches, 1880), Pulkowa (30), Nice (30), Greenwich (28; see a figure here given). Among the most distinguished makers of great telescope lenses may be named Sir Howard Grubb in England and Alvan Clark in America. The making of optical glass, for which the Messrs Chance of Birmingham are famous, is described at GLASS, Vol. V. p. 244. See also EQUATORIAL, OBSERVATORY.

See an address by Sir Howard Grubb, Royal Institution, 2d April 1886; *Nature*, xxxiv. 85. For the subject in general, see Sir John Herschel's *Telescope;* and for the history, the histories of astronomy and the monograph by Servus, *Geschichte des Fernrohrs* (1885).

Telford, THOMAS, engineer, was born in Westerkirk parish, Eskdale, Dumfriesshire, on 9th August 1757, the son of a shepherd; and during the intervals of his attendance at school young Telford or Telfer (so he was registered) followed the same calling, diligently employing his leisure moments in the perusal of whatever books were within his reach. At fourteen he learned the trade of a stone-mason at Langholm. In 1780 he removed to Edinburgh, and in 1782 to London, obtaining employment under Sir William Chambers on the erection of Somerset House. In 1784 he was appointed to superintend the erection of the resident commissioner's house at Portsmouth dockyard, a work which afforded Telford the opportunity of mastering the details of construction of docks, wharf-walls, &c. In 1787 he was appointed surveyor of public works for Shropshire; and his two bridges over the Severn at Montford and Buildwas gained for him the planning and superintendence of the Ellesmere Canal, to connect the navigation of the Severn, Dee, and Mersey (1793–1805). In 1790 he was appointed by the British Fishery Society to inspect their harbours; and in 1801 he received a commission from government to report on the public works required for Scotland. As a consequence the construction of the Caledonian Canal (q.v.) was entrusted to Telford, who also executed more than 1000 miles of road in the Highlands, Lanarkshire, and Dumfriesshire, and about 1200 bridges, besides churches, manses, harbours, &c. His next great work was the road from London to Holyhead, including the erection of the

Menai Suspension Bridge (see BRIDGE), and the last was the St Katharine's Docks (1826-28) in London. Among other works by him are, of bridges, the Conway, the Broomielaw at Glasgow (1833-36), and the Dean in Edinburgh (1831); of canals, the Macclesfield, the Birmingham and Liverpool Junction, the Gloucester and Berkeley, the Weaver system, the great tunnel ($1\frac{3}{4}$ miles long) on the Trent and Mersey; of harbours, Wick, Dundee, Peterhead, Banff, Fraserburgh, Fortrose, Cullen, Kirkwall, and Aberdeen. He was the first president of the Institute of Engineers; he supplied the nucleus of a library, and left towards it its first bequest of £2000. By Southey he was termed 'the Colossus of Roads' and 'Pontifex Maximus.' He died at Westminster, 2d September 1834.

See *Life* by himself (1838), which contains some specimens of Telford's homely poetry in its appendix, with its accompanying folio atlas of plans; and Smiles's *Lives of the Engineers* (vol. ii. 1861).

Tell, a district in the extreme north-west of Africa, stretches along the shores of the Mediterranean, and comprehends the corn-growing tracts extending south from the Mediterranean to the Atlas Mountains, and from west to east through Morocco, Algeria, and Tunis. The Tell is noticed under the articles MOROCCO and SAHARA.

Tell, WILLIAM, was, according to Swiss tradition, a countryman of Burglen in Uri, who early in the 14th century rescued his native district from the tyranny of Austria. The following is the generally accepted version of the story. Albert II., Duke of Austria and German emperor, was in 1307 striving to annex the Forest Cantons to his immediate possessions. Hermann Gessler, his *vogt* or steward, perpetrated atrocious cruelties on the inhabitants. Werner Stauffacher of Schwyz, Walter Fürst of Uri, father-in-law of Tell, and Arnold Melchthal of Unterwalden met on the Rütli Meadow, 7th November 1307, and solemnly swore they would expel their oppressors before the following New-year's Day. Gessler had placed the ducal hat of Austria on a pole in the market-place of Altorf and intimated that any one who passed it without uncovering would be punished without mercy. Tell and his boy failed to do reverence to the hat, and were sentenced to be put to death unless Tell, who was a famous bowman, could hit an apple placed on his son's head. Tell performed the feat. 'What,' asked Gessler, 'would you have done with the second arrow in your bow?' 'Shot you if I had killed my child,' was the reply. Tell was bound and thrown into a boat to be taken with Gessler and his men to the Castle of Küssnacht, the residence of the tyrant. A frightful storm burst forth. Tell alone could save the party. He was unbound and pulled the boat to a rocky ledge, 'Tell's Platte;' he there sprang on shore and disappeared. The tyrant landed and was passing through a defile, the 'Hohle Gasse' near Küssnacht, when Tell, who lay in ambush, shot him through the heart. A rising followed, and wars with Austria, which ended in the independence of Switzerland.

The story was told as true by Johannes von Müller in his great history of Switzerland. Schiller made it the subject of his greatest drama and Rossini of his best opera—and 'the patriot Tell' became the best-known hero the world had seen. Doubts, however, had been expressed as to the very existence of Tell. Already in 1754 Voltaire had cast a characteristic sneer at 'the apple story,' and in 1760 Freudenberger, a Bernese Protestant clergyman, published a pamphlet, *Tell, a Danish Fable*, pointing out that the story of the apple is the Scandinavian fable of Toko. His work was condemned by the government of Uri and burned by the common hangman. The doubts were not extinguished. The comparative mythologists showed that the Tell story was merely a Scandinavian form of an old Indo-Germanic myth (see Ideler, *Die Sage vom Schusse des Tell*, 1826). An excellent parallel is that in our own north-country ballad, 'Adam Bell, Clym of the Clough, and William of Cloudesley,' printed in Percy's *Reliques*. The 'master-shot' indeed is not the property alone of Aryan folklore, but is found among Samoyeds, Turks, and Mongolians alike. It was further found that Tell is first mentioned in 1470 in a ballad, between 1482 and 1488 in the *Chronicle* of M. Russ of Lucerne, and in 1511 in a play acted in Uri. The first makes Tell the hero of the apple story and the rising which followed. Russ and the Uri play take no notice of the apple story, but refer to the boat scene and the atrocities of the bailiffs. They make Tell the hero of the revolution. A MS. known as the *White Book of Sarnen* first combined the apple story and the atrocities. It makes the Rütli oath the pivot of events, and Stauffacher, not Tell, the hero. Tschudi in his *Swiss Chronicle* (1572) first melted all these incidents into a consistent narrative. He fixed the date of the Tell rising at 1407, and Von Müller, warned by the fate of Freudenberger, with palpable misgivings told the tale as true history (see Vischer, *Die Sage von der Befreiung der Waldstädte*, 1867). There is no trace of Tell to be found in contemporary records. His name did not appear where it should have done in lists connected with the *landesgemeinden* of the period; in the register of deaths at Schaddorf it had been forged. The story that the Tell chapel on Tell's Platte was built by a *landesgemeinde* held in 1388 at which 114 men were present who had known Tell was first heard of in 1759. The Tell chapels at Bürglen and the Hohle Gasse, represented as existing since the 14th century, belong to the 16th. Professor J. E. Kopp of Lucerne has shown that the date of the Tell rising is inconsistent with the history of the Forest Cantons. There was then no grievance against Albert II., who was a severe but just ruler and never guilty of any atrocity (see Kopp, *Urkunden zur Geschichte der Eidgenössischen Bund*, 1851). A complete record has been published of all the occupants of Küssnacht from 1250 to 1513. Among them there is no Gessler (see Rochholtz, *Tell und Gessler in Sage und Geschichte*, 1876). In short, there is no truth in any incident of the Tell legend. Although inconsistent with history, they, however, are not yet generally recognised as mythical. The people of the Forest Cantons cling even to the apple story. In 1890 a ferment was raised in Uri by the publication of a school history of Switzerland which did not mention Tell and the Rütli oath. Excellent French works on general history still represent all the incidents as historical, expressing a mere doubt as to the apple story; this is justified in a long article in the *Nouvelle Revue* of July 1891. It attributes disbelief in Tell to a conspiracy of German savants actuated by sycophancy, jealousy, and antipathy to liberal ideas. At the sex-centenary of Swiss independence celebrated in August 1891 truth and fiction were ingeniously blended, and the patriots of Uri were compensated for the scepticism of 'German professors' by the abiding faith of newspaper correspondents. See Albert Rilliet, *Les Origines de la Confédération Suisse, Histoire et Légende* (1868).

Tellez, GABRIEL, better known by his pen-name of *Tirso de Molina*, a Spanish dramatist of great reputation, was born in Madrid in 1585, entered the order of the Brothers of Charity at Toledo, and died prior of the monastery of Soria in 1648. Tellez was a friend and pupil of Lope de Vega,

whom he almost rivalled in facility of execution. His pieces are partly *Comedias*, partly Interludes, and *Autos Sacramentales* (originally about 300, of which but few survive), all displaying dramatic vitality, originality, and power of character-painting. The wit is rich and natural, and the language highly poetical. Some of his comedies still keep the stage. Among the best are *El Burlador de Sevilla* (*Don Juan*), *El Vergonzoso en Palacio*, *Don Gil de las Calzas Verdes*, and *Marta la Piadosa*. The best edition of his works is that of Hartzenbusch (12 vols. Madrid, 1839–42); there is a selection in the *Biblioteca de Autores Españoles* (vol. v. 1850). See a monograph by Muñoz Peña (Madrid, 1889).

Tellicherri, a seaport town and military station of British India, in the district of Malabar, Madras Presidency. The site of the town is very beautiful, and the neighbouring country highly productive. There is a natural breakwater abreast of the fort, formed by a reef of rocks running parallel to the shore. The town, with suburbs, occupies about 5 sq. m. Coffee, cardamoms, and sandalwood are the chief exports. The East India Company founded a factory here in 1683, which was reduced to a residency in 1766. The old citadel and residency survive. Pop. (1891) 27,196.

Tellurium (sym. Te, equiv. 128) is a chemical element, which some authorities place among the metals, and others among the non-metallic bodies or metalloids. Although in its outward characters it closely resembles the metals, its close analogies with sulphur and selenium indicate that its true place is amongst the metalloids. It possesses a high metallic lustre, and is bluish white in colour; it melts at about 932° (500° C.), and at a higher temperature is converted into a yellow vapour; it is a bad conductor of heat and electricity, and is very brittle. Its specific gravity is 6·24. When strongly heated in the air it burns with a blue flame and gives off white fumes of tellurous acid. Like sulphur and selenium, it is soluble in cold oil of vitriol, to which it gives a fine purple-red colour, and on dilution it is precipitated unchanged; in these respects it differs from all metals. In nitric acid it dissolves with oxidation.

Tellurium forms two compounds with oxygen —viz. *Tellurous acid*, TeO_2, and *Telluric acid*, TeO_3, corresponding to the oxides of sulphur. *Tellurous acid* exhibits very slight acid properties, and in the anhydrous state it combines with acids, and acts the part of a weak base. These salts have a metallic taste, and are said to act powerfully as emetics. The *telluric acid* has only a feeble affinity for bases, but it forms salts, which contain 1, 2, and 4 molecules of the acid to each molecule of base. Tellurium unites with hydrogen to form telluretted hydrogen, H_2Te, which is a gaseous body, analogous to sulphuretted hydrogen, and precipitates most of the metals from their solutions in the form of tellurides, which have a close analogy with the corresponding sulphides.

In experimenting upon the action of the salts of tellurium, it has been found that they possess the power of forming, in the body of a healthy person, compounds which impart to the breath, to the perspiration, and to the gases generated in the intestinal canal a disgusting fetor, which makes him a nuisance to every one he approaches; and this smell may last for weeks, although the quantity of tellurium that was administered did not exceed a quarter of a grain.

Tellurium is a rare substance, found chiefly in Transylvania, but discovered in other parts of Hungary, in North America, and in the Altaï silver mines. It sometimes occurs native, but more commonly as a telluride of gold, lead, or silver.

Tembu. See Kaffirs.

Temesvar, a royal free city of Hungary, consisting of the fortified city or 'citadel,' with four suburbs, on the Bega Canal, 160 miles SE. of Pesth by rail. It has a fine cathedral, an ancient castle, a magnificent episcopal residence, manufactures of flour, tobacco, cloth, silk, paper, leather, wool, and oil, and a brisk transit trade in grain, wax, honey, and brandy with Transylvania, Servia, and Roumania. Temesvar has endured a great number of sieges—the latest being that of 1849, when it was besieged and bombarded for 107 days by the Hungarian insurgents, but was relieved by Haynau. Pop. (1880) 33,694; (1890) 39,850.

Tempé, a famous mountain-gorge, some six miles long and 100 to 2000 paces broad, in the north-east of Thessaly, between the mountains of Olympus and Ossa. The river Peneus forces its way through the rocky ravine to the sea, and along its right bank runs the track, at some points hewn out of the rock. The vegetation is so rich and the scenery so grand that the name of Tempe became in ancient times a synonym for any beautiful valley, as the Tempe near Reate through which flowed the Velinus, and the Tempe in Sicily formed by the Helorus. Tempe was a favourite haunt of Apollo.

Tempera. See Distemper.

Temperament is a term which has been employed in Physiology ever since the time of Galen, to designate certain physical and mental characteristics presented by different persons. A fourfold classification was long universal, doubtless based on the old idea of four corporeal elements (see Medicine, Vol. VII. p. 116). But the two generally regarded as fundamental are the *sanguine* and the *melancholic*, the *phlegmatic* being a degree or modification of the sanguineous, and the *choleric* of the melancholic.

Some writers recognise a *nervous* temperament, in which the predominating characteristic is a great excitability of the nervous system, and an undue predominance of the emotional impulses—a temperament always associated with the sanguineous or the melancholic. The names of the jovial, mercurial, and saturnine temperaments are reflections of Astrology (q.v., Vol. I. p. 525). The artistic temperament is also a very current phrase. In both sexes the characteristics of the temperaments are far less manifest in old age than in earlier life. The different temperaments often merge so gradually into one another that very often it would be extremely difficult to decide to which variety any special case belongs.

Temperament is a system of compromise in the tuning of keyed instruments. Though the various intervals of the scale are spoken of broadly as consisting of tones and semitones, the successive tones are not all equal when given in just intonation according to harmonic law—i.e. so that the consonant intervals are in perfect tune; and as every note in the scale may become the keynote of another scale, if all these scales are to be given exactly a complete set of keys for each would be necessary. But it has been found in practice that by only a slight deviation from just intonation a much more limited keyboard, of twelve notes to the octave, gives results which do not offend the ordinary ear, though the discrepancy is distinguishable by a trained one. Up till about the beginning of the 19th century in Germany, till 1835 in France, and 1846 in Britain, the system adopted

was that known as *mean* temperament, by which the intervals in some keys were more exactly in tune than in others; some of the intervals in the less favoured keys, known as *wolf* intervals, being so unpleasantly out of tune as to cause composers to avoid these keys. This was remedied in a few instances by the use of two divided keys, one of which gave separately D♯ and E♭, and the other F♯ and G♭. The present practice, known as *equal* temperament, makes each tone and semitone in the octave approximately equal, so that every key is equally available; while at the same time every interval except the octave deviates slightly from just intonation. This deviation is more obvious on the organ, or still more the harmonium, than on the pianoforte; but it is of more practical moment in the orchestra, where keyed instruments are heard along with others playing in just intonation. There are many advocates of a system of just intonation, at all events as applied to special instruments; and various keyboards have been invented to obviate the mechanical difficulties. The subject is still a favourite battlefield of theorists. See Bosanquet on Musical Intervals and Temperament, and Helmholtz' *Sensations of Tone*.

Temperance. The moral codes of the great religions of the world have either enjoined abstinence from intoxicating drinks or have inculcated that strict sobriety which such abstinence secures; so that a very large, if not the larger, proportion of the human race has always avoided the use of such liquors. But their manufacture and consumption have, nevertheless, prevailed to such an extent as often to call for special methods of cure or prevention. During the 18th century the ravages of what Mr Lecky has called the 'gin epidemic' led to measures of a persuasive and legislative character, designed to check this social pest. Dr George Cheyne (1671–1743) was one of many medical practitioners who, early in the 18th century, denounced the use of ardent spirits; while men such as Dr Samuel Johnson and John Howard set an example of abstinence from all inebriating drinks. Dr Beddoes of Bristol, Dr Thomas Trotter (physician, to the Royal Navy), and Dr Erasmus Darwin were also advocates of the same practice. John Wesley forbade the members of his society to use 'drams,' and denounced the common vending and use of spirituous liquors in the strongest terms. Dr Benjamin Rush of Philadelphia endeavoured to promote a common action among the leading Christian bodies of the United States against the use of spirits as a beverage; early in the 19th century various resolutions were adopted by American church synods and associations; and the Massachusetts Society for the Suppression of Intemperance was formed early in 1813. Even prior to this a society formed at Moreau, New York state, April 30, 1808, excluded both spirits and wine except medicinally, or wine except at public dinners or in the Lord's Supper. In 1809 an Anti-Spirit Society was established at Greenfield, N.Y., and in 1818 at Hector, N.Y. There seems also evidence that at Skibbereen in Ireland there was established as early as 1817 a sort of benefit society on the basis of abstinence from all intoxicating drinks. No doubt there were likewise on both sides of the Atlantic not a few men and women who never or rarely touched any kind of alcoholic drink; but there was still an absence of any general and combined movement against the ordinary use of even distilled spirits. This lack was supplied by the formation of the American Temperance Society at Boston on February 13, 1826; and therefore to this event must be referred the origin of what is now known as the temperance movement, described by De Quincey as 'the most remarkable instance of a combined movement in society which history, perhaps, will be summoned to record.' The leaders of the American Temperance Society included many of the chief ministers and professors of the country; the *Journal of Humanity* became its weekly organ in 1829, up to which time eleven state societies with numerous local branches had been formed, having a membership of about 100,000 persons, of whom 1200 had been reclaimed from habits of intemperance. It was reported that fifty distilleries had stopped, and that at least 400 persons had abandoned the traffic. In the following five years the temperance cause in the United States made amazing advances, and this was especially the case in New York state, where Mr E. C. Delavan of Albany published the *Temperance Recorder* and the *American Temperance Intelligencer;* these circulated far beyond the state, which claimed 1652 societies in 698 towns, with 320,427 members. In this one state 1472 persons had ceased to sell spirits, and some towns were entirely free from the traffic. It had, however, become apparent that the limited terms of the pledge as one against distilled liquors only could not cope with the evil, for breweries began to increase, and much spirit was disguised and sent into the market under the name of 'wine.' The leaders of the cause became at length convinced that it was necessary to direct the attack against every form of intoxicating drink; and this conviction was strengthened by what had been taking place in the British Isles.

Copyright 1892 in U.S. by J. B. Lippincott Company.

Professor Edgar of Belfast learned, in the summer of 1829, of the work of the American Temperance Society, and on the 14th August a communication from him appeared in the *Belfast Newsletter*, calling upon the Christian public of Ireland to follow the example thus set. This led the Rev. G. W. Carr of New Ross, Wexford, to hold a meeting, August 20, and form a society in the Friends' Meeting-house of that town. On September 24 the Ulster Temperance Society was formed in Belfast, and at the close of the year 25 societies with 800 members had been organised, chiefly in the north of Ireland. The Dublin society issued in November the first of a series of tracts. In the following five years the Irish movement spread widely, and many societies, chiefly composed of Protestants, were formed—some on the basis of total abstinence, mainly due to Mr John Finch of Liverpool. In Scotland Mr John Dunlop, of Greenock, found an able coadjutor in Mr William Collins, who, with other friends, formed the Glasgow and West of Scotland Temperance Society, November 12, 1829. Two ladies had already founded a small women's society at Maryhill near Glasgow. Before the close of 1830 Scotland possessed 127 societies with 23,000 members; and the *Temperance Society Record* appeared monthly in 1830–35. In Scotland, as elsewhere, it was felt that to be effective action must be taken against fermented as well as distilled liquors.

The first temperance society in England was formed at Bradford, Yorkshire, on February 2, 1830, the chief mover having been Mr Henry Forbes, who had signed the pledge at Glasgow; and the Bradford society became the mother of others. At Stockton Heath, near Warrington, a society was established April 4, and at Manchester May 12. Societies were also formed at Bristol, Liverpool, Leeds, York, and Newcastle-on-Tyne; and the London society was converted in 1831 into a national association, under the name of 'The British and Foreign Temperance Society.' In 1834 Mr J. S. Buckingham, who was returned for Sheffield to the first Reform parliament, succeeded in obtaining a select committee of the House of Commons

to inquire into the causes, extent, and remedies of drunkenness. In the meantime the limitation of the pledge to abstinence from ardent spirits had proved a greater drawback than in other countries, because beer had for centuries been the popular beverage, and its use a cause of wide-spread drunkenness before ardent spirits were commonly sold. It was also an unfortunate coincidence that the Beer Act of 1830 had led to the opening of many thousands of new houses for the consumption of beer on the premises, and had aggravated the previous evils of the liquor traffic, contrary to the hopes of the framers of the bill, who thought it would diminish the use of ardent spirits and substitute for them 'good malt and hops which could injure nobody.'

Temperance societies on the anti-spirit basis had at the close of 1835 been established in all the British-American and Australian colonies, in India, the West Indies, the Sandwich Islands, the South Sea Islands, and in some continental countries, especially some parts of Germany and Sweden; and this continental movement was soon afterwards extended to Prussia, Russia, and Denmark. In British North America abstinence from all alcoholic beverages was common even under the old form of pledge, and on May 25, 1832, at St John, New Brunswick, a society was formed with a constitution expressly committing its members to abstinence from all intoxicating liquors, save as a medicine. It was, however, reserved for the Preston Temperance Society in England to apply such missionary power in the diffusion of the total abstinence principle as to justify for it the supremacy in the advocacy of the new reform. On September 1, 1832, seven members of the Preston society allowed Mr Joseph Livesey to attach their names to a pledge of total abstinence, and in later days it became common to speak of 'the seven men of Preston' as having commenced the new crusade. In fact, however, Mr Joseph Livesey was the only one of the seven who became greatly distinguished in this cause, his real Preston compeers being James Teare, Henry Anderton, Edward Grubb, Thomas Swindlehurst, and some others. The Preston society adopted both pledges, and it was not till 1835 that it resolved to make the total abstinence pledge a test of membership; but a Youths' Society had been formed in 1834 on the single basis of total abstinence. In the September of 1833, at one of the meetings of the Preston society, a working-man named Richard Turner, usually called 'Dicky Turner,' and who was a rough, humorous speaker, was insisting on the superiority of total abstinence over what was known as the 'moderation' system, and wishing to express himself very forcibly, he exclaimed, 'I'll be reet down out-and-out tee-tee-total for ever and ever.' The audience cheered, and Mr Livesey said, 'This shall be the name of our new pledge.' Dicky did not stutter, and the reduplication of the 't' in 'total' was simply an emphatic way of declaring his opinion. A conference of Lancashire and Cheshire societies was held at Manchester, September 24, 1834, when as a second pledge one of total abstinence was recommended; and at a second conference in Manchester, September 15 and 16, 1835, when thirty-one societies in Lancashire, Cheshire, and Yorkshire were represented, it was agreed to form the British Association for the Promotion of Temperance—the first general society in England on the total abstinence basis.

The years 1835-45 were years of great activity in the temperance cause throughout the world. In the United States the system of total abstinence was universally adopted in place of the limited anti-spirit principle. The American Temperance Union, with state and local societies in great numbers, continued the agitation, and laws affecting the liquor traffic were passed by several state legislatures. The Washingtonian Reform, which originated in Baltimore in 1840, was specially designed to reclaim the intemperate, and in the space of a few years it was estimated to have induced a quarter of a million of such persons to take the pledge. In England the British and Foreign Temperance Society practically ceased to exist. It had done much good work in its earliest years, but it would never accept a total abstinence pledge, even as a second one. In London the New British and Foreign Temperance Society was formed in 1836. It had adopted two pledges, one of simple personal abstinence called the short pledge, the other of abstinence coupled with a promise not to give strong drink to others, called the long pledge; and the disputes on this point rose to such a height that in May 1839 a division took place. Both societies unfortunately ran into debt, and in November 1842 they dissolved in favour of a new one, the National Temperance Society. In 1844 it organised a metropolitan temperance mission. District and county associations were organised in various parts, and by slow degrees a sentiment in favour of total abstinence, accompanied by its practice, became diffused throughout English society. One special line of labour was diligently prosecuted by Mr John Dunlop, who had settled in London, namely a movement in opposition to drinking usages in trades, especially those of a compulsory character. In Scotland the temperance cause had revived under the abstinence system; and at Falkirk, November 5, 1844, the Scottish Temperance League was founded, an event followed shortly after by the dissolution of the Western Temperance Union. But it is to Ireland that we must look at this period (1838-45) for the most extraordinary exhibition of temperance progress which any age or country has witnessed within an equal space of time. The total abstinence cause, though having many active and generous friends, had but slightly influenced the Roman Catholic population; but in the April of 1838 Father Mathew (q.v.) in Cork signed the total abstinence pledge at the instance of William Martin, a Quaker of that city. It is said in some books that Father Mathew's success as a temperance reformer was immediate; but the truth is that his work did not acquire a remarkable momentum till about the middle of 1839. During the next three years he visited nearly every part of Ireland, including the north, and administered the pledge to millions of men and women. The effect of his labours was visible in an enormous decrease in the consumption of spirits, as also in a lessening of drunkenness and the crimes arising out of it. In 1843 he visited England, giving the pledge to about 200,000 persons, including 60,940 in London. The first World's Temperance Convention, held in London in August 1846, was attended by 305 delegates, of whom twenty-eight were from the United States. It had been arranged by the National Temperance Society, which in 1856 was united with the London Temperance League. Since that date the N. T. League has been remarkably successful in carrying on temperance work among colleges and other educational bodies, as also in the army and royal navy. It has also held various congresses and conferences. By its means also various Nonconformist temperance societies have been formed. It has three organs—*Temperance Record* (weekly), *Temperance Mirror* (monthly), and *Medical Temperance Journal* (quarterly).

Although the temperance leaders in all places were almost invariably religious men, the great majority of Christian churches were not until of late years brought into recognised connection with the temperance movement. A ministerial temper-

ance conference convened by the British Temperance Association was held in Manchester in 1848, and a declaration adopted by the conference afterwards received 583 ministerial signatures. Prior to this the Personal Abstinence Society of United Presbyterian ministers, elders, and students had been formed in 1845; and all the religious bodies in Scotland have now temperance societies associated with them. It is the same in England, where the Congregationalists, Baptists, Methodists of all kinds, and Presbyterians have denominational societies. The great majority of the ministers, and nearly the whole of the students, are now abstainers. A Church of England conference, held in 1862, led to the formation of the Church of England Society, with Dr F. Close, the Dean of Carlisle, as president. In 1868 Archdeacon Sandford secured the appointment of a committee on intemperance by the Lower House of Convocation of the Province of Canterbury, and the valuable report of this committee was adopted in 1869, and widely circulated. It recommended among other things a legislative measure of local option on the ground of the excellent results arising from the exclusion of the drink traffic from numerous places in this province (upwards of 1400), by the will of the landowners. One important result of this report was the construction in 1873 of the Church of England Temperance Society on the dual basis, in order that, while total abstainers should form a distinct section, they should also be enabled to unite with non-abstainers desirous of diminishing sources of intemperance springing from social circumstances or legislation. By means of diocesan branches and a central executive much has been done to dispose the Established Church to take a more prominent part in temperance work, and the number of abstaining clergy and laity has probably increased sevenfold since 1873. The juvenile members of the society are all abstainers. The League of the Cross has been a means of promoting total abstinence among the Roman Catholics of the United Kingdom; and to Cardinal Manning's personal and official support this and other forms of temperance activity were greatly indebted.

The phrase 'Band of Hope' was first applied to juvenile societies in 1847, and under this felicitous title they have so greatly increased as to constitute a large department of the whole movement. It is estimated that upwards of two millions of young persons are embraced in Bands of Hope and other juvenile societies in the United Kingdom; and the United Kingdom Band of Hope Union—an extension of the London Band of Hope Union formed in 1855—is now one of the leading national organisations. The importance of securing the adhesion of young persons to the societies, and of training from childhood is fully recognised.

The abuses of friendly societies and benefit clubs by their connection with the public-house led to the formation of the Rechabite Order at Salford in 1835, and its members with those of the Sons of Temperance, and the Sons of the Phœnix (the last being almost confined to London), are numbered by many thousands. The order of Good Templars, which had long existed in America, was introduced into England by Mr Joseph Malins in 1868, and in less than seven years had so greatly spread through the United Kingdom as to number about a quarter of a million of members. A rupture in 1876, with other causes, made a large reduction in the membership, but the division has been healed, and the Good Templars throughout the world can still boast of a membership exceeding half a million. At the close of 1840 an institution was projected in London for insuring the lives of total abstainers. Seven years afterwards it was arranged to admit non-abstainers into a separate section, so that both classes would get the full benefit of their respective longevity. This office, under the name of the United Kingdom Temperance and General Provident Institution, is now one of the largest in the country, with a capital of upwards of five millions sterling.

Woman's vital relation to home life renders her deeply interested in all that concerns its welfare, and not only have women taken a leading personal part in the temperance movement, but numerous societies composed of their own sex have existed, and the British Women's Temperance Association, formed in 1876, has a network of branches in Great Britain and some branches in Ireland. It also forms a part of the Women's World's Christian Temperance Union.

The United Kingdom Alliance for the Legislative Suppression of the Liquor Traffic was formed June 1, 1853. Its first president was Sir W. C. Trevelyan, and its agencies of all kinds have for their special object the election of members to parliament favourable to its policy, in order to a measure of legislation which would enable every district to decide by a direct vote of the local electors whether the liquor traffic should exist therein or not. A Permissive Prohibitory Bill was brought into the House of Commons by the present writer in March 1864, but though repeatedly reintroduced it never obtained a second reading. In June 1880, however, a Local Option Resolution was carried by a majority of twenty-six. In 1881 and 1883 further resolutions were carried by majorities of forty-two and eighty-seven. The *Alliance News* (weekly) has the largest circulation of any temperance journal in the British Isles. The Blue Ribbon or Gospel Temperance movement occasioned extraordinary public demonstrations and large additions to the pledge.

Although some eminent medical total abstainers had ceased to prescribe alcohol as a medicine on the ground that it was needless, since other agents could be used with equal or better effect, it was not till the October of 1873 that a temperance hospital was opened in London, in which, while the visiting medical staff are authorised to give alcohol when they deem it necessary, the ordinary rule is the treatment, medical and surgical, of cases without alcohol. Buildings costing upwards of £50,000 have since been erected, and, besides a large number of out-patients, more than 7700 in-patients have been treated, the rate of mortality being a little over 6 per cent. Many very important and critical cases have been treated with complete success, and alcohol has not been administered in more than a fraction of cases (less than a quarter per cent.).

In Scotland the cause has probably a stronger hold numerically and politically than in any other section of the United Kingdom. The Scottish Temperance League and the Scottish Permissive Bill and Temperance Association have their headquarters in Glasgow, where their weekly organs, the *League Journal* and *Reformer*, are published. In Ireland the effect of the terrible years of famine, 1846–49, and the bitterness of political strife have acted prejudicially on the temperance cause, but the Presbyterian Church and the Episcopal Church of Ireland contain, especially the former, great numbers of abstainers, and the Irish Temperance League and the Irish Association for the Prevention of Intemperance direct from their headquarters in Belfast and Dublin a variety of operations. In the Roman Catholic Church several of the archbishops and other dignitaries are conducting a temperance work in connection with their ecclesiastical regulations. The League of the Cross is also active in some places. The

Sunday closing of public-houses has proved in Ireland (1878), as in Scotland (1853) and Wales (1881), a blessing appreciated by the great body of the people. See LICENSING LAWS.

In the United States the Anti-liquor Law of the state of Maine in 1851 gave a powerful stimulus to similar legislation; and though there has been great fluctuation in this respect, prohibitory laws, both imperative and permissive, exist in various states; and in Kansas, Maine, North Dakota, and South Dakota prohibition has been incorporated with their constitutions, so that the liquor traffic cannot be licensed even by the legislatures until a popular vote has rescinded such portion of the constitutions. At the close of the civil war in 1865 efforts were made to establish a National Temperance Society and publication house in New York, and that institution, besides circulating almost countless copies of publications, has performed much admirable work in convening the International Conference of 1876 and other conventions of a national character. The Women's Crusade against Whisky, which commenced at the close of 1873, led to the abandonment of the traffic by a large number of drink-vendors, and issued in the formation of the Women's Christian Temperance Union, which has expanded into the Women's World's Christian Temperance Union. The Red Ribbon and Blue Ribbon movements originated in the New England states, and, though the excitement occasioned by them and similar outbursts of moral enthusiasm is of necessity transitory, their effects have become part of that abiding influence which philanthropic reforms cannot but ensure.

In the Dominion of Canada the Temperance Act of 1878 permits counties and cities to adopt local prohibition, and the various provincial legislatures are empowered to pass such measures as they think to be in accordance with public opinion. In India a marked revival of temperance has proceeded from the action of the Anglo-Indian Temperance Association, and the Abkhari (Excise) System is being more carefully administered. The Army Temperance Association has upwards of 17,000 European soldiers enrolled as abstainers, and publishes a monthly paper, *On Guard*. It has the highest official patronage, as its effect upon the health and *morale* of the troops is altogether beneficial. New Zealand and Australia have been taking of late years a high rank in the temperance movement; and legislation of a local option character has either been obtained, or is in course of alteration, so as to permit of the fullest expression of public opinion as to the liquor traffic. See LIQUOR LAWS.

As to the continent of Europe the retrospect is not generally pleasing. The great wave of temperance feeling which between 1845 and 1864 caused many parts of Germany and Austria to be largely converted to abstinence from spirit-drinking subsided during the political feuds and wars which followed; but the need of restrictive measures is deeply felt by some of the leading statesmen of Germany. In Switzerland, France, and Belgium the free-trade drink system has proved pregnant with social and moral evils of the gravest description. In Holland an anti-spirit society was established many years ago, and total abstinence work has been set on foot. In Belgium there are societies for promoting sobriety, but they do not insist upon abstinence from even ardent spirits. In Switzerland some societies under the name of the Blue Cross inculcate abstinence from all inebriating drinks. Russia is the victim of *vodka* (corn-spirit) and the resolve of the government not to permit the revenue from spirits to be diminished. Sweden and Norway, however, have many temperance societies and Good Templar lodges, and both these countries have shown how much may be done in the reduction of intemperance by salutary legislation. Sweden about 1830 had an unhappy repute for its drunkenness, notwithstanding its excellent system of public education; but the prohibition of distillation on private farms, and the power given to reduce or prevent the sale of liquor in rural localities have proved of so much advantage that Sweden and Norway have risen to a position hardly, if at all, equalled by any other country.

Objections and Replies.—(1) It is objected that temperance or moderation and not abstinence is the proper rule to be followed as to alcoholic drinks; to which it is replied that all temperance involves partial abstinence, the degree of the abstinence being regulated by the nature of the article concerned, and that alcoholic drinks are of such a kind as to call for entire abstinence from them, except when used medicinally. Considering temperance as signifying sobriety, it is urged that abstinence involves sobriety, and is its best security. (2) It is objected that abstinence is an example of the ascetic principle, and, therefore, not suitable for universal adoption. It is answered that there is an asceticism enjoined by religion and reason as necessary to the control of sensuous desire, and that abstinence from strong drink both illustrates and assists this control; but it is denied that it is asceticism in any unnatural sense, since it is friendly to the proper use and enjoyment of the harmless bounties of Providence. (3) It is objected that abstinence is opposed to the general experience of mankind, which ought to be accepted as a guide in such matters; the answer being that the experience of mankind is in favour of abstinence as compared with indulgence in strong drink, and that the common use of intoxicating drink in some countries is no more an argument in its favour than the prevalence of many forms of social and moral evils. (4) It is objected that countries such as the United Kingdom, where alcoholic liquor has been long and largely used, are much superior to other countries where its use is prohibited. It is answered that this fact is not to be more fairly pleaded for drinking than for drunkenness, and that the superiority referred to has its root in causes altogether different from the use of drink, and would be far more striking if such drink were not consumed by the superior races. (5) It is objected that health and strength cannot be fully maintained without the moderate use of alcohol, and that longevity is promoted by it. The answers to this objection are various: (*a*) that nations and tribes both ancient and modern, distinguished for health, strength, and longevity, have not used any alcoholic drink; (*b*) that medical testimonies in great abundance have been published in favour of total abstinence, one of which in 1847, signed by 2000 medical men, asserted that 'total and universal abstinence from intoxicating liquors of all kinds would greatly conduce to the health, the happiness, the morality, and the prosperity of the human race;' (*c*) that experiments made by Dr Parkes of Netley Hospital, and the statistics of insurance and friendly societies, show that abstinence is associated with the greatest powers of endurance, diminished sickness, and long life. In the United Kingdom Temperance and Provident Institution, out of 4856 expected claims in twenty-five years (1866–90) the actual claims were only 3423 or 70 per cent., while in the general section consisting of moderate drinkers, out of 7277 expected claims the actual were 7034 or 96 per cent., or 26 per cent. in favour of the abstainers. (6) It is objected that the combustion of alcohol in the body is a source of heat, and, therefore, that it is a true food. The

reply is that this was Liebig's theory, but was generally abandoned after the publication of the great essay of MM. Llemand, Perrin, and Duroy, whose experiments seem to show that alcohol was ejected from the system undecomposed. This position has in its turn been disputed; but there is no doubt that at least a portion of the alcohol imbibed leaves the system undecomposed. It is not certain what becomes of the rest, but the combustion theory is opposed to the facts, that heat is reduced and not increased after alcohol is imbibed, and that none of its derivatives have been discovered. (7) It is objected that the use of intoxicating drink is sanctioned by Scripture, by Christ's example, by the miracle at Cana, by the Lord's Supper, and by St Paul's advice to Timothy. The replies are (*a*) that the Scripture commendation of wine is limited to it as a natural product, but that whenever its intoxicating quality is noted it is always referred to with condemnation as a 'mocker,' a 'serpent,' a 'transgressor' and a 'poison;' (*b*) that the example of Christ cannot be quoted on the side of strong drink unless it were known whether He used intoxicating drink, and to what extent, and that His true example is that of love to God and man, which is best exhibited by abstinence from drinks which are deceitful and destructive; (*c*) that the wine made at Cana would be innocent and not such as was condemned by the prophets, and that there is high patristic authority for assuming that the miracle consisted in hastening the natural process by which the water of the grape is converted into rich and nutritious juice; (*d*) that it is the 'fruit of the vine,' and not alcohol, which is to be used in the Lord's Supper; (*e*) that St Paul's advice was of a medical character; that Timothy's previous abstinence was not rebuked; and that St Paul has laid down the principle of the avoidance of that which is even useful in order to the preservation of our fellowmen—a principle sufficient to justify total abstinence, even if alcoholic liquors were not physically injurious but beneficial.

On the question of the prohibition of the liquor traffic there has been much controversy. Its opponents have contended that it is an invasion of personal liberty; that even when imposed by a majority it is a violation of the rights of the minority; and that all that is really required is such a magisterial and police supervision as will repress drunkenness as much as possible, and inflict deterrent penalties on offenders. To this statement various answers are returned. With regard to the violation of personal liberty the prohibitionists maintain that in one sense all law interferes with liberty. A good law interferes with the liberty to do wrong. Therefore, they say, assuming that the common sale of drink wrongs the public, a law interfering with this wrong is in accord with true liberty. And the licensing system has been tried for hundreds of years, and, as judged by its fruits, is confessed a melancholy failure.

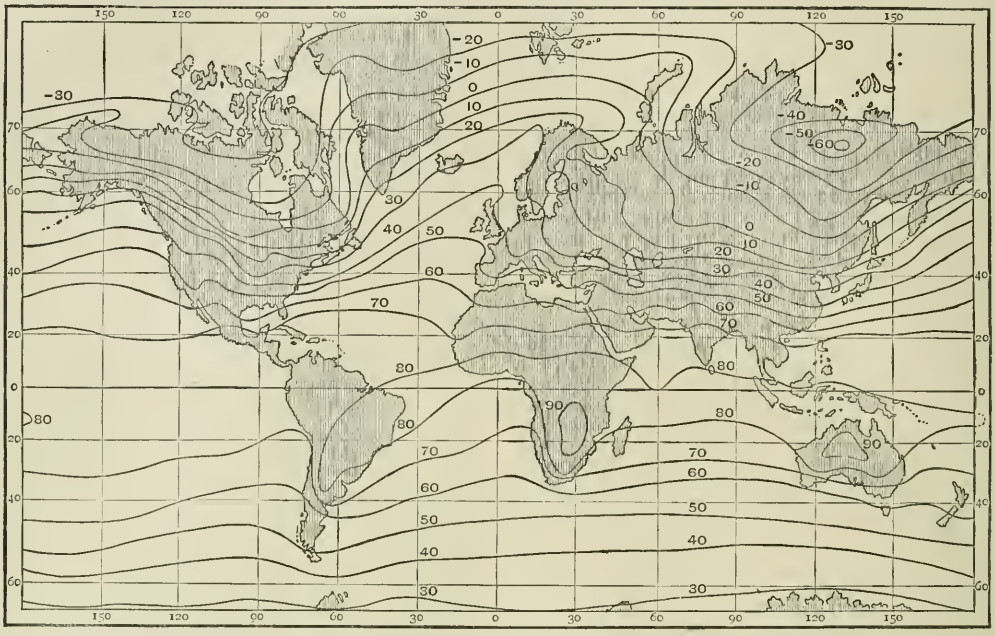
The consumption per head of the population of the different alcoholic beverages was, in the United Kingdom in 1897: wine 0·39 gall., beer 31·3 galls., spirits 1·02 gall. The corresponding figures in France were: wine 21·8 galls., beer 5·1 galls., spirits 1·89 gall.; in Germany: wine 1·34 gall., beer 25·5 galls., spirits 1·89 gall.; in the United States: wine 0·44 gall., beer 12·2 galls., spirits 0·84 gall. The total amount of revenue derived from alcohol was in 1897-8 in the United Kingdom £34,427,000 (wine £1,325,000, beer £11,405,000, spirits £20,097,000). In France the total amount was £20,418,000, Germany £12,621,000, and the United States £25,518,000.

See *The Temperance Problem and Social Reform*, by Rowntree and Sherwell (1899; 7th ed. 1900), a very comprehensive work; *The Curse of Britain*, by Rev. W. R. Baker; *Bacchus* (Prize Essay), by Dr R. B. Grindrod; *Anti-Bacchus*, by Rev. B. Parsons; the works of Dr F. R. Lees; *The Teetotaler's Companion*, by Peter Burne; *Nephalism*, by Professor Miller; *Bacchus Dethroned*, by F. Powell; *Bases of the Temperance Reform* and *Christendom and the Drink Curse*, by Dr Dawson Burns; *The Christian Church and the Temperance Reformation* (Prize Essay), by Rev. James Smith; *The Case for Total Abstinence* (Prize Essay), by J. W. Lacey; *Temperance Cyclopædia*, by Dr W. Reid; the *Foundation of Death*, by A. Gustafson. On the physiological aspect are *The Use and Abuse of Alcoholic Liquors*, afterwards republished as *The Physiology of Temperance and Total Abstinence* (Prize Essay), by Dr W. B. Carpenter; *Alcohol, its Place and Power*, by Professor Miller; the *Cantor Lectures on Alcohol*, by Dr B. W. Richardson. On biblical criticism and the Bible wine question are the *Temperance Bible Commentary*, by Dr F. R. Lees and Dr Dawson Burns; the *Practical Bible Temperance Commentary*, by Rev. A. Stewart; *Scripture Testimony*, by Rev. Dr W. Ritchie; *Wines Scriptural and Ecclesiastical*, by Dr N. Kerr. The only volume on the other side is *The Wines of the Bible*, by Rev. A. M. Wilson. On temperance economics is *Our National Resources and how they are wasted*, by W. Hoyle; of history and biography there are *Handbook of Temperance History*, edited by Robert Rae; *Temperance History*, by Dr Dawson Burns; *Temperance Workers and the Temperance Movement*, by P. T. Winskill. For young persons there are *Morning Dew Drops*, by Mrs Balfour, the *Lesson Book*, by Dr B. W. Richardson, and the *Temperance Primer*, by Dr J. J. Ridge. On temperance legislation are the House of Commons' Select Committee's *Report*, 1834; *The Argument for Prohibition* (Prize Essay), by Dr Lees, and Dr Lees's *Condensed Argument* and *Replies to One Hundred Objections*; *Reports* of the Committees on Intemperance appointed by the Convocations of Canterbury and York; *Local Option*, by W. S. Caine, W. Hoyle, and Dr Dawson Burns. Among a multitude of American works, Senator H. W. Blair's *History of the Temperance Reform*, and *The Liquor Problem in all Ages*, by the Rev. Dr Daniel Dorchester, are of special value. Reports of various temperance conventions and congresses contain many valuable papers on all branches of the question. See also the articles ALCOHOLISM, INEBRIATES, LICENSING LAWS, LIQUOR LAWS, and those on eminent advocates of temperance, such as Fulton, Mathew, George Cruikshank, and Archdeacon Farrar.

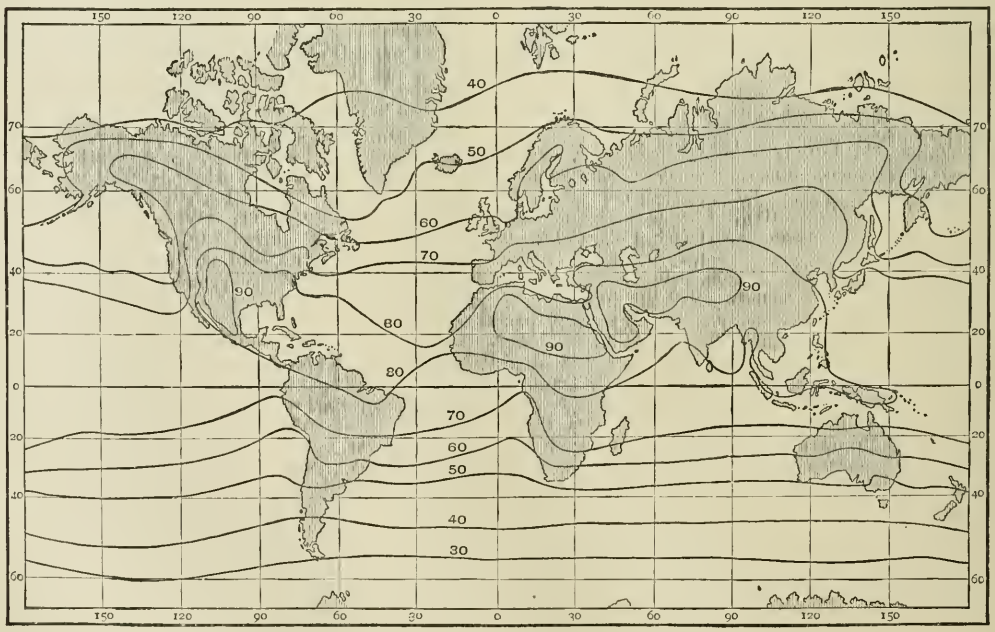
Temperature is the thermal condition of a body which determines the interchange of heat between it and other bodies. Our first ideas of temperature are derived from our sensations of hot and cold. As explained under Heat (q.v.), the effect of adding heat to a body is to make it hotter, unless it is at its melting or boiling point. This rise of temperature is accompanied by volume changes, on which all our practical methods of measuring temperature depend (see THERMOMETER). Now, although the idea of temperatnre is familiar enough, its true significance is difficult to understand. So-called thermometric measurements of temperature are not measurements in the strict scientific sense of the term. They are simply the comparison of certain other effects which accompany change of temperature in special bodies. A scientific measure of temperature should be independent of any particular substance, and should depend solely upon the fundamental properties of heat itself. This absolute measure of temperature was first given by Lord Kelvin (Sir W. Thomson), who based his system on Carnot's thermodynamic cycle (see THERMODYNAMICS). The kinetic theory of Gases (q.v.) has given us a definition of temperature in terms of the kinetic energies of the molecules. The assumption is that the molecules are free from molecular forces; the conclusion is in agreement with Boyle's, Gay-Lussac's, and Charles's laws. As no gas obeys these laws rigorously, the inference is that intermolecular actions come into play, so that only part of the temperature can be

expressed in terms of the kinetic energies of the molecules. The same is true, but in a much greater degree, for liquids and solids, for which as yet no kinetic theory has been formulated.

From experiments made by Kelvin and Joule, the absolute zero of temperature was found to be 274 centigrade degrees below the freezing-point of water, or – 461° on the Fahrenheit scale. This



Isothermal Lines showing the Mean Temperature of the Globe for January.



Isothermal Lines showing the Mean Temperature of the Globe for July.

agrees almost exactly with the value deduced from the kinetic theory of gases. From our present standpoint, therefore, we cannot expect to get a colder temperature. The coldest natural temperature hitherto registered on the earth's surface is – 88·8° F., which was observed in January 1886 at Verkhoyansk in Siberia (67° 34′ N. lat. and 133° 51′ E. long.). Olszewski has, in his experiments on the liquefaction of the gases, measured temperatures as low as – 373° F. by means of a hydrogen thermometer. Guesses have been made from time to time as to the temperature of space, Pouillet,

for example, putting it at – 238° F. and Fourier at – 58°. From our present physical outlook, however, the phrase 'temperature of space' is meaningless. Only where matter is can a true temperature exist. A thermometer placed in space will receive radiations from all sides, and the temperature indicated will depend on the power it has to transform these radiations into the irregular motions which constitute heat in a body. An ideal thermometer, transparent to all radiations, and capable only of receiving heat by contact with other bodies, would remain unaffected if isolated in space.

In meteorology the distribution of atmospheric temperature is one of the most important problems calling for discussion. The mean annual temperature over the whole surface of land and sea is perhaps about 45° F. At Verkhoyansk the lowest monthly mean averages – 63·6° F. The highest monthly mean averaged over several years may be set down at fully 110° F., and is experienced in the north-western parts of India, where the thermometer in free shaded air not unfrequently touches 125° F. Loomis in his *Meteorology* gives 133° F. as the highest authentic reading, made in the Great Desert of Africa. Exceptionally high readings made by travellers in Arabian and African deserts must, however, be accepted with great caution. It is indeed no easy matter satisfactorily to measure air temperatures, especially when they are high. It is not enough to shade the thermometer from direct sun rays. It must be shaded as effectually from reflected radiations from earth and sky; and at the same time the air must be free and not confined. To facilitate the study of the distribution of temperature at the earth's surface, it is usual to construct charts of *isotherms*. These are lines, each of which is drawn through all places having the same mean monthly, mean seasonal, or mean annual temperature. The most recent and complete charts of this character are those prepared and published by Dr Buchan in his *Challenger* Report on Air and Ocean Temperatures (1890). Two of these charts are reproduced here on a diminished scale. They show the mean temperature (Fahrenheit) of the globe for January and July, the typical winter and summer or summer and winter months for all regions on the earth's surface. A glance will indicate how greatly the distribution of land and sea influences the distribution of temperature. In January the great land-areas in the northern hemisphere are much colder than the ocean-areas at the same latitude; in July this relation is reversed. For a full discussion of the facts embodied in these and the charts for the other months of the year, as well as of the related facts referring to barometer pressure, rainfall, humidity, diurnal changes, &c., see the elaborate Report mentioned above. A concise abstract, given by Dr Buchan himself, will be found in the *Proceedings of the Royal Geographical Society* (March 1891).

The periodic changes of atmospheric temperature are due to the sun. The earth itself has, however, a distinct temperature, which increases at the rate of 1° F. for every 50 or 60 feet of descent through the few miles of crust accessible to us. Upon this real earth temperature the mean annual temperature of the air must to a large extent depend. According to Professor Langley, the surface of the moon with its long 'day' of a fortnight never gets hotter than the freezing-point of water, however brightly it may be shone upon. This shows that the moon is intrinsically much cooler than the earth. See also EARTH, CLIMATE, SEASONS, SEA.

TEMPERATURE OF THE BODY.—In the article ANIMAL HEAT the general principles of the subject have been discussed; it remains to consider more in detail the variations of temperature in health and disease. The temperature differs in different parts of the body; it is lower and more variable on the surface of the skin than in internal organs or closed cavities. Observations are usually made with the thermometer held either in the armpit or under the tongue; the latter gives results less than half a degree (F.) higher than the former. In the healthy adult in temperate climates the average temperature in the armpit is about 98° F., but undergoes periodical daily variations of nearly a degree in each direction from the mean, being lowest between 2 and 6 A.M., highest between 5 and 8 P.M. A slight rise takes place during the digestion of each meal. In the tropics the temperature is a little higher (less than 1°); it is less diminished in very cold climates. It is slightly higher in childhood, and slightly lower in old age. A persistent elevation or depression of the temperature of more than a degree beyond the limits thus indicated is good evidence that there is some departure from health. In some chronic diseases, especially chronic Bright's disease, diabetes, and myxœdema, the temperature is persistently lowered; in the last it may be as low as 95°. But elevation of temperature is of much more common occurrence and much more important. It occurs in connection with all acute inflammations and all febrile diseases; and careful observations of its degree and its changes from day to day or hour to hour afford one of the most reliable guides to the diagnosis of many diseases, and the estimation of their severity and probable result. Generally speaking, a temperature of 99·5°—101·5° F. may be regarded as slightly febrile; up to 103·5° F. as moderately febrile; up to 106° F. as highly febrile; and above that as hyperpyretic, and, with rare exceptions, as indicative of great danger.

See Wunderlich's *Medical Thermometry*, and Aitken's *Science and Practice of Medicine*.

Tempering. See STEEL, Vol. IX. p. 710.

Templars, a famous military order, which, like the Hospitallers and the Teutonic Knights, owed its origin to the Crusades. In the year 1119 two comrades of Godfrey de Bouillon, Hugues de Payen and Geoffroi de Saint-Adhémar, bound themselves and seven other French knights to guard pilgrims to the holy places from the attacks of the Saracens, taking before the patriarch of Jerusalem solemn vows of chastity, poverty, and obedience. King Baldwin II. gave them for quarters part of his palace, which was built on the site of the Temple of Solomon close to the church of the Holy Sepulchre. Hence they took their name as Templars (*pauperes commilitones Christi templique Salomonici*), and the houses of the order, as at Paris and London, that of the Temple. At the Council of Troyes (1128) Bernard of Clairvaux drew up its rule in seventy-two statutes, substantially the groundwork of the statutes as finally revised in the middle of the 13th century. The order at first consisted of knights alone, but later its members were grouped as knights, all of noble birth, chaplains, and men-at-arms (*fratres servientes*), besides mercenaries, retainers, and craftsmen affiliated, and enjoying its protection. The knights took the vows for life or for a certain period, and they alone wore the white linen mantle, with the eight-pointed red cross on the left shoulder (granted by Pope Eugenius III.), and white linen girdle; black or brown garments were worn by all others. The seal of the order showed the Temple, later two riders—a Templar and a helpless pilgrim—on one horse. The discipline of the order was austere, excluding all needless luxury or display in food, dress, or armour, and all worldly pleasures were forbidden—hawking and hunting all animals, with

the characteristic exception of the lion. Married brethren were admitted, but no woman might enter the order, and all brethren were enjoined to shun the kiss of woman, even of mother or sister. The beard was worn, the hair cut short, and all slept alone in shirt and breeches, with a light constantly burning. At the head of the whole order stood the Grand-master; under him Masters, Grand Priors, Commanders, or Preceptors ruled the various provinces of Jerusalem, Tripoli, Antioch and Cyprus, Portugal, Castile and Leon, Aragon, France and Anvergne, Aquitaine and Poitou, Provence, England, Germany, Italy (Middle and Upper), Apulia and Sicily. Second in command to the Grand-master stood the Seneschal, his deputy; next the Marshal, whose business, moreover, was to provide arms, horses, and all the material of war. Visitors-general conveyed the commands of the Grand-master and convent or chapter of Jerusalem to the various provinces, exercised discipline, and settled disputes. The Prior or Preceptor of the kingdom of Jerusalem, also styled 'Grand-preceptor of the Temple,' was also general treasurer of the order. The Drapier had general charge of the clothing; the Standard-bearer (*balcanifer*) bore the glorious *bauséant* or war-banner (half black and half white, with the legend, *Non nobis, non nobis, Domine, sed nomini tuo da gloriam*) to the field; the Turcopilar commanded the Turcopoles, a body of light horse, natives of Syria and Palestine, in the pay of the order; the Guardian of the Chapel (*custos capellæ*) had charge of the portable chapel and the appurtenances of the altar, always carried into the field. The Templars were, by a papal bull in 1172, rendered independent of the authority of the bishops, owning allegiance to the pope alone, the immediate bishop of the entire order; and, moreover, they were allowed to have chaplains within their own ranks to whom they might confess, to erect oratories for divine worship within their bounds, and to enjoy exemption from all taxes and tithes, and from interdict. Their houses enjoyed right of sanctuary, and they often preserved the treasure of kings and nobles.

The Templars, at once knights and monks, realised the two dearest of mediæval ideals, and men of the highest courage and purest devotion flocked into their ranks, bringing with them their wealth to fill their coffers. Already by 1260 the order is said to have numbered 20,000 knights, and these perhaps the finest fighting men the world has seen. Never in the history of the world did men fling away their lives more gloriously for a hopeless cause; never did a Templar play the coward in the hour of danger, nor, when all hope was lost, barter his soul to a Moslem conqueror in return for his life. Charges of pride, of immorality and impieties, of secret heresies, and even of betraying Frederic II. to the infidel (1229) and St Louis to the Soldan of Egypt (1250) were yet to be hurled against the order; never, from the beginning to the end of their two centuries of history, was a Templar charged with cowardice before the enemy. It was their proud boast that 20,000 of their number perished for the cause in Palestine; of their twenty-two Grand-masters seven died on the field of battle, five of their wounds, one of voluntary starvation a prisoner in the hands of Saladin. The most famous successors of Hugues de Payen (died 1136) were Bernard de Tremelai, who fell at Ascalon in 1153; Eudes de Saint-Amand (died 1179), who won a glorious victory over Saladin at Ascalon (1177), only to fall next year into the sultan's hands after a disastrous battle; Gerard de Riderfort, who suffered a terrible defeat near Nazareth in 1187, a second at Hittin two months later, and died in battle under the walls of Acre in 1189; Robert de Sable, who aided Richard Cœur de Lion to gain a glorious victory in the plain of Arsouf (1191), and bought from him the island of Cyprus, which was soon transferred to Guy de Lusignan, whereupon Acre became the seat of the order, the famous stronghold of Pilgrim's Castle being built, whose stupendous ruins exist to this day; Peter de Montaigu, whose courage helped to take Damietta in 1219; Hermann de Perigord, who rebuilt the fortress of Safed; Guillaume de Sonnac, slain beside St Louis at the Nile in 1250; Thomas Berard, an Englishman, under whom Safed was lost in 1266, Jaffa and Antioch in 1268; and Guillaume de Beaujeu, who lost Tripoli in 1290, and fell in the bloody capture of Acre in 1291. The remnant of the Templars sailed to Cyprus, and the latest dying gleams of the order's vigour in the East were the rash attempts to capture Alexandria (1300), and to establish a settlement at Tortosa (1300–2) under the last and most ill-fated of its grand-masters.

The Templars had failed in their work; their usefulness was past; the order had now only to sink into extinction in one of the darkest tragedies of history. Their wealth and pride had sowed a harvest of fear and hatred; their loyalty to the pope and their exceptional privileges had long since aroused the jealousy of the bishops; their bitter quarrels with the Hospitallers, which blazed into open warfare in Palestine in 1243, had shocked the moral sense of Christendom; and the exclusiveness and secrecy with which all their affairs were conducted opened a door for all manner of sinister suspicions among the populace. Philip the Fair of France was a king who covered with a thin veneer of piety a character of complete unscrupulousness; he had succeeded in placing Clement V., a miserable creature of his own, upon the papal throne (1305), and in his minister Guillaume de Nogaret and the officers of the Inquisition he found servants of character unscrupulous as his own. His unfortunate Flemish wars had brought him into desperate financial difficulties, and his treasury was now completely exhausted in spite of extortionate taxation, a shameful debasement of the currency, and the merciless plunder of the Jews and the Lombard bankers. In the wealth of the Templars he saw a tempting prize, and the train of treachery was soon complete. Doubtless their numbers and even their wealth are enormously exaggerated by historians; Schottmüller assumes that in France alone there were 15,000 brethren, and over 20,000 in the entire order; Mr Lea thinks that at the end there may have been as many as 1500 knights. The Grand-master, Jacques de Molay, was summoned from Cyprus by the pope in 1306; he came, bringing with him the treasure of the order, and awaited his fate in France. On the 13th October 1307, which Döllinger in one of his latest lectures calls an outstanding *dies nefastus* in human history, the Grand-master and 140 Templars were seized at the Temple and flung into prison. Two degraded Templars supplied some of the charges the king required; tortures, infamous beyond the infamies of the Inquisition, provided the remainder. A habitual denial of Christ, spitting upon the cross, the worship of hideous images, travesty of the holy communion and of the sacrifice of the mass, sorceries, unnatural lusts, *oscula inhonesta* and other indecencies—such were the confessions suggested to and wrung from men racked by the agonies of inhuman tortures to which as many as thirty-six knights succumbed in Paris alone. In August 1308 Clement sent throughout Christendom the 127 articles of interrogation for the accused, and evidence in detail self-contradictory beyond all parallel was quickly accumulated. In the 225 witnesses sent to the papal commission (1310–11) from various parts of France the depositions, as Mr Lea

points out, occur most suspiciously in groups of identity according to the bishops from whose preliminary tribunals they had come. Philip held a so-called national assembly at Tours (May 1308) which obsequiously expressed its approval of the condemnation. The pope now took the formal responsibility upon himself by personally examining seventy-two Templars brought before him, when those who had already confessed under torture confirmed their confessions, knowing well that the penalty of retractation was burning forthwith as a relapsed heretic. The pope contended that the fate of the order as an institution must be submitted to a general council. Meantime, to the public commission appointed to examine into the charges at Paris, to give the order an opportunity of being heard in its defence, and to report there came (March 1310) as many as 546 Templars who offered to defend the order against all the charges—blunt, unlearned soldiers, deprived of their chiefs, and weak with torture, long imprisonment, cold and hunger. Four of these were at length commissioned to be present at the investigation on behalf of the order, when suddenly the commission was startled by the news that the provincial council of Sens was about to sentence without further hearing those Templars who had offered to defend the order as relapsed heretics in regard to their former confessions. On 12th May 1310 fifty-four knights were slowly burned to death, refusing in the midst of the most awful agonies to perjure themselves by false confessions. The commission at once suspended its sittings, but at length, after many delays, on June 5, 1311, transmitted its report to Clement to help the General Council in its deliberations. The closing act in this dreary and tangled drama of papal duplicity was Clement's failure to gain over the Council at Vienne, and the suppression of the order without formal condemnation, by the bull *Vox in excelso* (March 22, 1312). The bull *Ad providam* (May 2) laid it under perpetual inhibition, and transferred its property to the Hospital of St John of Jerusalem. The persons of the Templars were handed over to the provincial councils, with the exception of the chiefs of the order, who were reserved to the jurisdiction of the holy see—a vain hope for which they had left their inferior brethren to their fate. At length, on March 19, 1314, Jacques de Molay and the gray-haired Geoffroy de Charney, Master of Normandy, were brought from prison to receive judgment, when, to the dismay of the churchmen and the astonishment of all, they rose and solemnly declared their innocence and the blamelessness of the order. That same day, on the Isle des Juifs in the Seine, they were slowly roasted to death, declaring with their last breath that the confession formerly wrung from them by torture was untrue. A strange tradition asserts that from the stake the Grand-master summoned both the pope and the king to meet him at the bar of Almighty God within a year, and history tells us that within the year both went to their account.

In England the trials were conducted with much less inhumanity, and it was only direct pressure from the pope that persuaded the king to permit torture to be applied. The charges for the most part failed to be established, and most of the prisoners were granted penances and permitted to escape with a formal abjuration, while a fair provision was made for their support. The last Master of the Temple in England, William de la More, died a prisoner in the Tower, to the last maintaining the innocence of the order. The memory of the various preceptories and possessions in England, Scotland, and Ireland survives in place-names; the round Temple Church in London, consecrated in 1185, was restored by the Benchers of the Inner and Middle Temple (1839–42) at a cost of £70,000. In Spain, Portugal, and Germany the order was found innocent; almost everywhere in Italy, save in the case of six at Florence, the charges broke down. Everywhere the larger part of their property was given to the Hospitallers, and even in France the king was in great part forced by public opinion to forego his prey.

The literature almost forms a library; here we can name only Raynouard, *Monumens hist. rel. à la Condemnation des Chevaliers du Temple* (1813); Wilcke, *Geschichte des Tempelherrenorden* (3 vols. Leip. 1826–35; new ed. 1860); Michelet, *Histoire de France* (vol. iii.) and *Procès des Templiers* (2 vols. 1841–51); Havemann, *Geschichte des Ausgangs des Tempelherrenordens* (Stutt. 1846); Loiseleur, *La doctrine secrète des Templiers* (1872), an ingenious but unreliable work; Merzdorf, *Geheimstatuten des Ordens der Tempelherren* (Halle, 1877), a work not to be trusted; H. de Curzon, *La règle du Temple* (1886), the most reliable book on this part of the subject; Konrad Schottmüller, *Der Untergang des Templer-Ordens* (2 vols. Berlin, 1887), the most thorough-going of later apologies, and perhaps the best work on the subject; Hans Prutz, *Entwicklung und Untergang des Tempelherrenordens* (Berlin, 1888), the most learned of more recent attacks upon the order, but marred by laborious attempts to construct a preposterous case of Catharist heresy. Ranke (*Weltgeschichte*, 8 Theil, 1887) follows Hammer-Purgstall (*Die Schuld der Templer*, 1855) in thinking that the order had fallen away from Christian faith, and adopted a body of secret and heretical doctrine, which had originated in their contact with Islam in the East; but, as Döllinger points out (*Akademische Vorträge*, vol. iii., Munich, 1891), he is hesitating and cautious, and makes many reservations, while he was evidently not acquainted with the most recent works on the subject. In English there are Addison's excellent *History of the Knights Templars, the Temple Church, and the Temple* (2d ed. 1842); Haye's *Persecution of the Knights Templars* (Edin. 1865); Froude's three interesting but superficial lectures (*Good Words*, 1886; reprinted in *Spanish Story of the Armada*, &c., 1892); and especially Henry C. Lea's admirable *History of the Inquisition* (vol. iii. 1888). *The Templars' Trials* (1888), by J. Shallow, contributes little to the question.

Temple (Lat. *templum*; cf. Gr. *temenos*, from *temnein*, 'to cut off,' and so 'set apart'), a place or building dedicated to the worship of a god or gods, and amongst most peoples rendered impressive by the noblest architecture and richest adornment available. The history of Greek temple-building is largely the history of Greek Architecture, and is discussed at that head. See also the articles on Olympia, Ephesus, Athens, &c. For other than Greek temples, see Roman Architecture, Pantheon, Rome; India (*Architecture*), Pagoda, Elephanta, Ellora; Egypt (Vol. IV. pp. 235, 236), Edfu, Abu-Simbel, Philæ; China (Vol. III. p. 187), Peking; Baalbek, Palmyra, Boro Budor, Teocalli, &c., where illustrations of many types of temple will be found.

The Temple of Jerusalem has quite exceptional interest for us. When David brought the ark of Jehovah to Jerusalem, he pitched a tent for it within his citadel, and offered sacrifices before it. The *Temple of Solomon* replaced this temporary sanctuary, and in like manner consisted essentially of a chamber to contain the ark, and a court in front for the worshippers and their sacrifices. This was the common type of ancient temples, especially in Phœnicia, save that in them the place of the ark was taken by a sacred cippus ('pillar') or image. It was therefore natural that the Hebrew king, whose own subjects were unskilled in architecture, should send to Hiram, the great temple-building king of Tyre, for architects and workmen, and that the plan and decoration of the new sanctuary closely followed Phœnician models. The 'house,' as was often the case in greater temples, consisted of two divisions—the adytum, 'oracle,' or chamber of the

ark, and an antechamber, in which stood the table of showbread, ten candlesticks of gold, and other articles of sacred furniture. The former was a cube of 20 cubits, or 30 feet; the antechamber had the same breadth, but was 40 cubits long and 20 high. In front of this again was a portico 10 cubits deep. Both the oracle and the outer chamber had folding-doors; the inner walls were lined with cedar and richly overlaid with gold, the motive of the ornament being the Phœnician cherub and palm-tree. Two cherubs with outstretched wings stood in the adytum and formed a sort of baldachin over the ark. The roof was probably high-pitched, and supported on wooden pillars (1 Kings, x. 12). There were windows, either in the gables or in a sort of clerestory that rose above the triple tier of small chambers by which the main building was encased on all sides except the front. Of the façade we have no account, but perhaps we may conclude from the description of Ezekiel's ideal temple that the portico was adorned with slender turrets like those shown on numismatic representations of the temple at Paphos. In front of the porch stood two pillars of bronze, 18 cubits high, with lotus-shaped capitals. Similar free-standing pillars are seen on coins in front of the temple of Paphos, and the same feature reappears in other eastern temples. We read of an inner and an outer court; the former was the proper court of the temple, the latter was the court of the palace as well as of the sanctuary, which thus presented itself as essentially the royal chapel. Later kings of Judah made considerable changes in and about the temple; thus Jer. xxxvi. 10 speaks of a 'new gate' in the 'higher court,' which is perhaps the same with the 'new court' of 2 Chron. xx. 5. Solomon's temple was burned by Nebuzaradan, Nebuchadnezzar's general, in the year 588 B.C.

The Temple of Zerubbabel, completed in 516 B.C., after long efforts and much discouragement, was designed, according to Ezra, vi. 3, to exceed the old in magnitude. But whether the dimensions there specified (a breadth and height of 60 cubits) were actually attained seems doubtful in view of Hag. ii. 3. In this temple, as in that of Herod, the folding-doors of the adytum were replaced by a veil or curtain; the altar in front of the house was a great platform of stone; the furniture was inferior in splendour; the ark was wanting; and there was only one golden candlestick. In the course of time a multitude of subordinate buildings grew up round the 'house,' in accordance with the requirements of a more elaborate priestly ritual. The circuit was fortified; and the approach to it from the higher ground on the north-west was further covered by a citadel, called the Acra or Baris. At the time of Pompey's siege (63 B.C.) the temple complex was an almost impregnable stronghold, strengthened on its weakest side (to the north) by great towers and a deep ditch.

The Temple of Herod, commenced by Herod the Great in his eighteenth year (about January 19 B.C.), was new from the foundations and, with its outer courts and surrounding colonnades, covered double the old area. To form so large a level space on the hill-top of Zion enormous substructures were necessary, except along the east side, where the colonnade rested on old works ascribed to Solomon, and was accordingly known as Solomon's porch (John, x. 23; Acts, iii. 11; v. 12). According to Josephus, the southern and eastern colonnades were each a stadium, or 600 feet, in length, and the whole circuit of the plateau, including the citadel of Antonia, which stood at the north-west corner, and replaced the Baris, was six stadia. The citadel, which was occupied by the garrison, was of course not holy ground; but neither was the adjacent temple enclosure, connected with the Antonia by a flight of stairs, and usually called the outer court, or, by modern writers, the Court of the Gentiles. Besides its porticos or colonnades, the outer court had various buildings connected with the priestly service, and also contained, near one of the western entrances, the council chamber of the Sanhedrim. It was here too that the money-changers and dealers in articles required for sacrifice had their tables and stalls. Towards the centre of this temple enclosure was a quadrangular platform, lying east and west—the 'inner court.' This, according to Josephus, was surrounded on all sides by walls, of which the external height was 40 cubits, and the internal 25 cubits, its floor being thus 15 cubits above the level of the outer court. On three sides it was surrounded by flights of steps; and the whole was cut off from the rest of the enclosure by a stone balustrade, 3 cubits high, with pillars at regular intervals bearing Greek and Latin inscriptions forbidding the alien to pass on pain of death. The eastern wall of this inner court was pierced by one gate; the north and south walls had four each; the west wall was unbroken. The eastern gate was exceptionally splendid, being made of 'Corinthian brass' and not merely overlaid like the others with silver and gold. The eastern and smaller portion of the inner court was walled off from the rest and known as the Court of the Women. The larger western portion, the Court of the Men (of Israel), stood on a somewhat higher level, and, besides having gates of its own on the north and south, was entered from the Court of the Women by the large 'Nicanor' gate; either this or the gate of Corinthian brass already mentioned was the 'Beautiful Gate' of Acts, iii. 2. The inner court was colonnaded all round, and there were chambers or 'treasuries' against the inner wall. In the middle of the Court of the Men stood the temple proper, again on a higher level, reached by a flight of twelve steps. Its ground-plan was the same as that of Solomon's temple, but its height, obviously with a view to harmony with the larger surroundings, was greater (60 cubits?), and the porch was 100 cubits broad and 100 cubits high. The 'holy place' (as it is usually called) contained the candlestick with seven lamps, the table of showbread, and the altar of incense; the 'holy of holies,' separated by an exceedingly thick and heavy veil, was empty. In front of the fane was the stone altar, 50 cubits square and 15 high, according to Josephus. Round temple and altar ran a stone fence, about a cubit in height, which marked off the so-called Court of the Priests from the area accessible to the laity. The fane proper was completed eighteen months after its commencement, but the 'building' of Herod's temple in the larger sense of the word was still in progress when our Lord began His ministry (John, ii. 20) and was not in fact finished till the procuratorship of Albinus (62–64 A.D.). The whole was burned to the ground when Jerusalem was taken by Titus (August 70 A.D.).

Those scholars who accept Josephus' measurements (he wrote from memory and some years after the temple had been destroyed) necessarily hold that the temple enclosure occupied only a portion of the present Haram area, which measures about 1500 feet from north to south, with a breadth of some 922 feet. Others, however, regard Josephus' figures as much too small, and, broadly speaking, consider that the whole of the Haram area was levelled up by Herod. According to the first view, the so-called Sakhra or 'Dome of the Rock' fell outside the temple area, but the supporters of the second view generally accept the tradition according to which the Sakhra marks the site of the holy of holies. It can be shown, however, that this tradition does not go further back

than the reign of Abd al-Melik (691 A.D.). It is agreed on all hands that the south-west angle of the Haram area is the south-west angle of Herod's temple, and that the line of the west wall of that area is the west wall of the temple, or of the temple and Antonia. Two of the most important data for the modern topographer seem to be the arch known as Robinson's arch at the south-west corner, and that known as Wilson's arch, 600 feet to the north of it; they seem to correspond to the two more southerly gates on the west mentioned by Josephus, which led respectively to the southern and northern porticos of the temple enclosure. The best judges, such as Petrie, believe that nothing older than Herod is found in the extant western walls and substructures. Of other supposed data it is to be observed that, if Josephus' measurements are correct, the arch substructures on the south, known as 'Solomon's Stables,' are post-Herodian; on this view they are to be identified with the substructures of Justinian's church mentioned by Procopius. The so-called 'Golden Gate' in the eastern wall of the Haram area is certainly post-Herodian.

'Temple' by Robertson Smith in the *Ency. Brit.*; also Schürer, art. 'Temple' in Riehm's *Bibl. Wörterbuch*. See also the article JERUSALEM, Vol. VI. p. 308.

Temple. See INNS OF COURT, TEMPLARS.

Temple, FREDERICK, since 1896 Archbishop of Canterbury, was born 30th November 1821, the son of an officer, at Leukas in the Ionian Islands. He was educated at Tiverton and at Balliol College, Oxford, where in 1842 he graduated double-first, and was subsequently fellow and tutor of his college. Successively principal of Kneller Hall Training College, inspector of schools, and headmaster of Rugby, he became conspicuous in the theological world in 1860 as author of the first of the *Essays and Reviews* (q.v.). In 1868–70 he supported the disestablishment of the Irish Church, and was in 1869 consecrated Bishop of Exeter—a Broad Church successor to the High Church Dr Phillpotts (q.v.)—in spite of strong clerical opposition. He proved an admirable administrator, and in 1885 was promoted to the see of London. His *Sermons preached in Rugby Chapel* appeared in 1861; he was Bampton lecturer in 1884, and has taken an active part in temperance reform.

Temple, RICHARD GRENVILLE, EARL (1711–79), elder brother of George Grenville (q.v.), is mainly known as having from 1752 to 1761 held office under the elder Pitt, who had married his sister; as having bitterly opposed Bute; and as having broken with Pitt (Chatham) on the question of the Stamp Act in 1766, soon after which time he ceased to take any prominent part in public affairs.

Temple, SIR WILLIAM, diplomatist and essay-writer, was the eldest son of Sir John Temple, Master of the Rolls in Ireland, and of Mary Hammond, sister of the well-known royalist divine, and was born at Blackfriars in London in 1628. He studied two years at Emmanuel College, Cambridge, where he had Cudworth for his tutor, but at nineteen went abroad on his travels, falling in love with Dorothy Osborne (1627–95) in the Isle of Wight on his way to France. His own father sat for Chichester in the Long Parliament, while Sir Peter Osborne was governor of Guernsey and a strong royalist, and naturally disliked the match. But the lovers were constant in their affection, and their seven years of separation gave opportunity for those delightful letters of Dorothy's, the charm of which defies the touch of time. Temple travelled in France, Spain, and Holland, married Dorothy in January 1655, lived some years in studious retirement in Ireland, and was returned for Carlow to the convention parliament at Dublin in 1660. Three years later he settled finally in England; in 1665 was sent on a secret mission to the Bishop of Münster; and on his return was created a baronet and appointed resident at the court of Brussels. His most important diplomatic success was the famous treaty of 1668, known as the Triple Alliance, by which England, Holland, and Sweden united to curb the ambitious schemes of France. This negotiation was accomplished in five days, in conjunction with the great Dutch statesman De Witt, but was rendered vain through the treachery of Charles II. in the secret Treaty of Dover (1670). Temple also took part in the congress of Aix-la-Chapelle (May 1668), and soon after was appointed ambassador at the Hague. He had his share in the long congress at Nimeguen, and was recalled in June 1671 a few months before the beginning of the shameful war between England and Holland. By the Treaty of Westminster (February 1674) Temple ended the war, and, after declining both the embassy to Spain and the secretaryship of state, went again ambassador to Holland. In 1677 he assisted in bringing about the marriage of the Prince of Orange with the Princess Mary. Charles II. in vain offered him again the secretaryship of state; and in the confusion of the Popish Plot accepted his proposed constitutional remedy of a reformed privy-council of thirty persons, by whose deliberations to be guided in all public affairs. As might have been foreseen, so numerous a council, under such an unprincipled sovereign as Charles II., and in times of such fierce faction and widespread corruption, proved an utter failure. For some little time an inner council of four—Temple, Halifax, Essex, and Sunderland—attempted to control public business, but Temple, who was too honest for his fellows, soon felt himself being ousted even from this, and retired to his villa at Sheen, where he lived till 1686, thereafter at Moor Park in Surrey.

When the Revolution placed William III. on the throne Temple was again offered the secretaryship of state, but again refused. His son, the sole survivor of seven children, was made secretary for war, but a week after drowned himself in the Thames, his mind being unable to bear the burden of responsibility. The remainder of his days Temple gave to letters and to gardening. The king occasionally consulted him, and during great part of this period he had with him as his secretary young Jonathan Swift, who regarded his stately self-complacent patron with more fear than affection, but ultimately became his literary executor. Temple died at Moor Park, January 27, 1699, and was buried beside his wife in Westminster Abbey, his heart beneath the sun-dial at Moor Park.

As a writer Temple is now known chiefly by his historical *Memoirs* (1691, 1709) and his *Miscellanea* (1679, 1692), a collection of essays on various subjects—government, trade, gardening, heroic virtue, poetry. The second part contains the essay 'Upon the Ancient and Modern Learning,' which opened the famous controversy on the Letters of Phalaris. Temple has been considered one of the reformers of English style—'the first writer,' says Dr Johnson, 'who gave cadence to English prose.' His style wears a singularly modern air, and is smooth, flowing, and agreeable. 'What can be more pleasant,' says Charles Lamb, 'than the way in which the retired statesman peeps out in his essays, penned in his delightful retreat at Sheen? They scent of Nimeguen and the Hague. Scarce an authority is quoted under an ambassador.' Temple's pretensions to learning are merely amusing, and

he has little real weight as a political writer, but he expatiates very pleasantly on foreign travel and country life, on flowers and fruits, on parterres, terrace-walks, and fountains. His epicurean temperament is happily and characteristically displayed in the last words of his last essay: 'When all is done human life is at the greatest and best but like a froward child, that must be played with and humoured a little to keep it quiet till it falls asleep, and then the care is over.'

His collected works fill 4 vols. (1814). The older Lives by Boyer, Swift, and Temple's sister, Lady Giffard, were superseded by the elaborate *Memoirs* by Thomas Peregrine Courtenay (2 vols. 1836), reviewed by Macaulay in a well-known and brilliant essay. The *Letters* of Dorothy Osborne, seventy-one in number, written during the last two years of their seven years' courtship, mostly from Chicksands in Bedfordshire, were admirably edited by E. A. Parry (1888).

Temple Bar, a London gateway, dividing Fleet Street from the Strand, the City from the shire. Rebuilt after the Great Fire by Wren in 1669–73 at a cost of £1398, it was removed in 1878–79, and re-erected in Theobalds Park, Cheshunt, in 1888. Its site is marked by a memorial, surmounted by an amazing griffin, and erected in 1880 at a cost of £11,550.

Templemore, a town of County Tipperary, which takes its name from a commandery of the Knights Templars, and is situated on the river Suir, 8 miles N. of Thurles by rail. Pop. 2800.

Temple Society, a body of German Christians who wait for the second coming of Christ. They separated from the church in Würtemberg and formed a separate sect; and many of them settled in Palestine in 1868, where they now have colonies at Haifa (q.v.), Jaffa, Sarona, and near Jerusalem, distinguished for industry, enterprise, and success. There may be about 5000 in all of the community, of whom about 1300 are in Palestine.

Temporal Power. See POPE.

Tenacity is that property of matter by which it resists being pulled asunder. Liquids and gases have no tenacity. In technical language, the tenacity of a substance is the greatest longitudinal stress that it can bear without being torn asunder. For example, steel bars have a tenacity of between 50 and 60 tons weight per square inch, whereas oak has a tenacity of not quite 7. With regard to metals it is found that forging and wire-drawing increase their tenacity. See STRENGTH OF MATERIALS.

Tenant, in English law, means a person who holds land under another; the payments and services which he owes to his superior constitute his tenure. Inasmuch as all land is held of the crown, no subject can be more than a tenant of land; even he who is practically absolute owner is described in legal language as tenant in fee simple. The estates in land known to the early law were of two kinds; a man might be tenant for his own life (under the crown or under a subject lord), or he might be tenant in fee, that is, he might hold to him and his heirs: both these estates were freeholds—i.e. estates worthy the acceptance of a free man. The statute *De Donis*, passed in 1285, introduced the tenant in fee tail—i.e. a fee *taillé*, cut down or restricted to heirs of the body of the tenant; see article ENTAIL. A person who held for the life of another was called tenant *pur autre vie;* this was a freehold interest, considered less certain than the interest of one who held for his own life. To prevent fraud, it is provided by statute that a person holding *pur autre vie* may be required to produce the person for whose life he holds. A tenant for his own life, or for the life of another, is a limited owner; he may not do any act which impairs the value of the inheritance; he may not, e.g., open mines or cut timber; nor may he dispose of the land to the prejudice of his successors. But the power to work mines, to grant long leases, and even to mortgage or sell the land was frequently conferred on limited owners by settlements, and similar powers are now conferred by statute, and especially by the Settled Land Act of 1882. As the protection of the courts was extended to persons occupying land under tenants in fee or for life, they also came to be called tenants. Thus, a farmer holding land for a fixed term was a *tenant for years:* if he held at the pleasure of his landlord he was a *tenant at will*, but if the landlord accepted annual rent from him this was enough to make him *tenant from year to year;* he could not then be turned out without the reasonable notice required by law. When land was held by two or more persons jointly, with benefit of survivorship, they were called *joint-tenants.* If they held the same property, their interests being separate and distinct, they were *tenants in common.* On the death of a tenant in common his share goes not to the survivors, but to his own heir or executor. A joint-tenant or a tenant in common may protect himself against waste or alienation of the property by any of his co-owners; he may also, according to modern statutes, compel a severance of the property. In this connection the word tenant is used with a certain laxity, for we speak of joint-tenants or tenants in common of money, &c., although personal property is not, strictly speaking, a subject of tenure. In popular language, tenant usually means a person holding land or house property for a term of years, or from year to year, under a contract with the owner. See TENURE, LANDLORD, and LAND LAWS. For an explanation of the connection between tenure and ownership, see Williams' *Law of Real Property* (new ed. 1887).

Tenasserim (*Ta-neng-tha-ri*), acquired by Britain after the war in 1825, the southernmost division of Burma (q.v.), is a long narrow strip of territory between the sea and the mountains of the Siamese frontier. Area, 46,590 sq. m.; pop. (1881) 825,741; (1891) 971,660. There are seven districts—the town of Maulmain, Taung-ngu, Schwe-gyin, Salwen, Amherst, Tavoy, and Mergni; the chief towns being Maulmain, Taung-ngu, and Tavoy. The town of Tenasserim, which had, through wars and other misfortunes, sunk to be in 1881 a village of only 577 inhabitants, stands 33 miles from the sea at the junction of the Great and Little Tenasserim rivers, the former of which has a total course of about 400 miles.

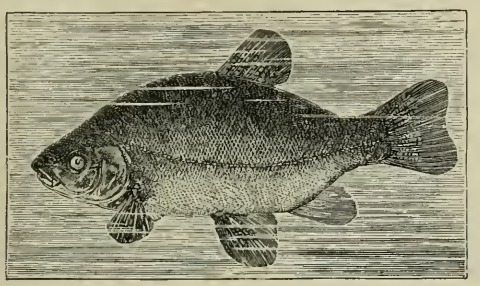
Tenbury, a market-town of Worcestershire, on the Teme, 22 miles NW. of Worcester. It has a spa, discovered in 1839, and St Michael's College, founded in 1855 by the Rev. Sir F. Gore Ouseley (q.v.). Pop. 2000.

Tenby, a thriving watering-place of Pembrokeshire, South Wales, 9½ miles E. of Pembroke and 276 W. of London, is finely seated on a rocky headland overlooking Carmarthen Bay. The Cymric *Din-bach y Pysgod* ('fishy little fortress'), it was one of the Flemish colonies planted by Henry I. in Pembrokeshire, and retains a long stretch of its ancient walls, strengthened by Queen Elizabeth in 1588, and a fragment of a castle, whence in 1471 the future Henry VII. escaped to Brittany. Its mild climate, fine level sands, and capital bathing have been the making of the place, which has an interesting Gothic church (1250) with a spire 152 feet high, a colossal marble statue of the Prince Consort (1865), and a fort (1868) on St Catherine's Island. It is an ancient municipal borough, and with Pembroke (q.v.) and five other towns returns one member to parliament. Pop. (1861) 2982;

(1891) 4542—much increased during the season, which lasts from June to October.

See P. H. Gosse's *Tenby; a Seaside Holiday* (1856); Mrs Hall's *History of Tenby* (2d ed. 1873); and also Cross's *Life of George Eliot*, under date 1856.

Tench (*Tinca*), a genus of fishes of the Carp family (Cyprinidæ), represented by a single species, *Tinca vulgaris*. The thick body is covered with small scales and abundant mucus; there is a short barbel at each side of the mouth; the pharyngeal teeth are in a single row and slightly hooked. The tench lives in lakes and rivers in France, Germany, Austria, and more rarely in England, usually in muddy waters. It is of a deep yellowish-brown colour, more rarely golden or greenish. Instances



Tench (*Tinca vulgaris*).

have occurred of its attaining a length of almost three feet, but a tench of half that length is unusually large. It is very tenacious of life, and, like the carp, can be conveyed to a distance alive in wet moss. It spawns in May and June, depositing its spawn among aquatic plants. The ova are very small and very numerous. In the winter the fish remains dormant in the mud. The flesh is soft and insipid, except when it is very well fed, when it becomes delicate and pleasant. It is commonly placed in ponds along with carp. Angling for tench resembles angling for carp.

Tencin, Madame de (Claudine Alexandrine Guérin), a clever writer but worthless woman, was born at Grenoble in 1681, and entered the religious life, but soon found its restraints intolerable. Finally, in 1714, she came to Paris, where her wit and beauty soon attracted to her a crowd of lovers, among them personages so great as the Regent and Cardinal Dubois. She had much political influence, was a bitter enemy of the Jansenists, enriched herself, and helped the fortunes of her brother the Cardinal Pierre Guérin de Tencin (1680–1758). But her importance died with the regent and the cardinal in 1723. In 1726 she lay a short time in the Bastille, after the tragic scandal caused by one of her lovers shooting himself in her house. Her later life was more decorous, and her salon became one of the most popular in Paris. She died 4th December 1749. One of her oldest lovers was Fontenelle; D'Alembert was one of her children. Her romances, *Mémoires du Comte de Comminges* (1735), *Le Siége de Calais* (1739), and *Les Malheurs de l'Amour* (1747), show taste, passion, and style, with all the 18th-century limitations. They resemble the romances of Madame de La Fayette in many points, but they lack the peculiar charm that lives in everything written by that admirable woman. Madame de Tencin's *Correspondance* with her brother appeared at Paris in 1790; the *Lettres au Duc de Richelieu* in 1806. See Barthélemy's *Mémoires Secrets de Mme. de Tencin* (Grenoble, 1790).

Tender, as a legal term, means the formal offer to perform some obligation incumbent on the person tendering. It is most frequently used in reference to the payment of money which is due. Whenever a tender of the debt is properly made the legal consequence is this, that if the money is refused the creditor will have to pay the costs of any action he may bring to recover it, and cannot claim interest afterwards. In case such an action is brought, the debtor has nothing to do but to plead that he duly tendered the money, and if he then pay into court the sum which he had formerly tendered the other party must stop the action, or continue it at his own risk. In order, however, that a tender should have the above effect, it must have been duly made—that is to say, it must have been made without imposing any conditions on the creditor, and at the proper time and place. The tender must be in money, and not by bill of exchange; but Bank of England notes are a good tender for all sums above £5. If the debt is beyond 40s., it ought to be in gold, so far as it goes. Though other bank-notes than Bank of England notes are often tendered, the creditor is not bound to accept them; but if he take them without any specific objection, then it will be a sufficient discharge. The gold coinage of colonies may be made current by proclamation; and so might foreign coin. A tender of a larger sum than is due is good, but the debtor may not require change to be given. Nor must any condition be annexed to the tender, not even the condition of giving a stamped receipt; but a person receiving payment is bound to fill up a stamped receipt on its being tendered to him, and to pay the stamp; and his refusal subjects him to a penalty of £10. A tender of payment must, in general, be made to the creditor at the place he has indicated, and it is the duty of the debtor to find out and pay the creditor. It is, however, enough that a tenant be ready to pay the rent on the premises at the time it is due, it being the landlord's duty to send or call for it, for the land is the proper debtor, and that is the place to make demand in the first instance. See Roscoe, *Evidence at Nisi Prius*. In Scotland, Bank of England notes are not legal tender. In the United States all the gold coins are good; and also the silver dollar for any amount, when the contrary is not expressly stated in the contract. Smaller silver coins are good up to ten dollars. United States notes are legal tender for all debts save duties on imports and interest on the public debt. Foreign coins are not legal tender.

Tendon, the white fibrous tissue reaching from the end of a muscle to bone or some other structure which is to serve as a fixed attachment for it, or which it is intended to move. Tendons have been divided into (1) *Funicular*, or rope-like, as the long tendon of the biceps muscle of the arm; (2) *Fascicular*, as the short tendon of that muscle, and as the great majority of tendons generally; and (3) *Aponeurotic* or tendinous expansions, sometimes of considerable extent, and serviceable in strengthening the walls of cavities, as, for example, the tendons of the abdominal muscles. The tendons commence by separate fascicles from the end of each muscular fibre, and they similarly terminate by separate fascicles in distinct depressions in the bones, besides being closely incorporated with the periosteum. In some birds whose tendons are black the periosteum is black also. If a tendon is ruptured by an accident, or divided by the surgeon (tenotomy), the two ends, if not too far separated, unite with extreme readiness, by the formation of intervening plastic material, which soon acquires great firmness. The tendons most frequently ruptured are the Achilles Tendon (q.v.) and the tendons of the rectus femoris and the triceps humeri.

Amongst the diseases of tendons are *inflammation* and one of the forms of Whitlow (q.v.) known as *Paronychia gravis*, or *tendinous whitlow*, in

which 'the tendons and their sheaths in the finger and hand are the seat of a severe and often most destructive inflammation, which, though often confined to one finger, not unfrequently extends to the hand and arm, attacking not only the tendons and softer parts, but exposing the bones, and disorganising the joints' (Holmes). A permanently bent finger, from adhesion of the tendon to its sheath, is a common result in severe cases of whitlow of this kind. Tendons may also be inflamed as the result of gout or rheumatism, and not very unfrequently they are the seat of syphilitic enlargements or other tumours. Fibrous tumours and small cartilaginous enlargements are often found in tendons.

Tenebræ. See GOOD FRIDAY.

Tenedos (*Bosdscha Ada*), a Turkish island in the Ægean Sea, off the Troad, and 12 miles S. of the entrance to the Dardanelles. It is 8 miles long and 2 to 4 broad, and is rocky, but not unproductive, with 7000 inhabitants. Tenedo is the chief town. Opposite Tenedos is Besika Bay (q.v.).

Teneriffe, PEAK OF, or PICO DE TEIDE, a famous dormant volcano, the highest summit in the Canary Islands (q.v.), stands in the south-west of the island of Tenerife, and is 12,200 feet above sea-level. The lower slopes of the mountain are covered with forests, or laid out in extensive meadows, yielding rich grass; but the upper ridges and the Peak, properly so called, are wild, barren, and rugged in appearance. The Peak El Piton and its two inferior neighbours, the Montana Blanco and Chahorra (9880 feet), rise from a rugged circular plain of lava debris and pumice, 7000 feet above sea-level, about 8 miles in diameter, and fenced in by an almost perpendicular wall of rock. From the crevices sulphurous vapours are constantly exhaling. The wall of the crater at the top is formed of broken and jagged porphyritic lava rocks, is elliptical, 300 feet in diameter, and 70 deep. The colour of the whole is white. There is an ice cave at an altitude of 11,000 feet. The Peak can be seen more than 100 miles off. In 1795 and 1798 there was volcanic activity here.

See *Tenerife*, by C. Piazzi Smyth (1858), who made a series of experiments here; Olivia M. Stone (who ascended the peak), *Tenerife and its Six Satellites* (new ed. 1889); G. W. Strettell, *Tenerife* (1890).

Tenesmus (Gr. *teinein*, 'to strain') is the term applied in Medicine to a straining and painful effort to relieve the bowels when no fæcal matter is present in the rectum; the effort being excited by some adjacent source of irritation. It is a common symptom in dysentery, irritation of the bladder, stricture of the urethra, &c.

Teniers, DAVID, the Elder, a Flemish master, was born at Antwerp in 1582. A pupil of Elsheimer at Rome and Rubens at Antwerp, he was admitted to the painters' guild of St Luke in his native city, and died there on 29th July 1649. His subjects are in general homely, the interiors of public-houses, rustic games, weddings, and the like; but they are full of reality, charm of colour, and happy ease of composition.—DAVID TENIERS, the Younger, son of the preceding, was born at Antwerp, 15th December 1610. He received his first lessons from his father, and the influence of his own contemporary, Adrian Brouwer, is strongly marked on his earlier work. He rose quickly to distinction, enjoying the favour and friendship of the Archduke Leopold William, Don Juan, bastard son of Philip IV. of Austria, the Prince of Orange, the Bishop of Ghent, and other dignitaries. His first wife was a daughter of the painter Brenghel. He was admitted 'master' of the guild of St Luke in 1632, and in 1644 was elected its president by the common council of Antwerp; in 1647 he took up his abode at Brussels, where he died, 25th April 1690. Of his pictures John Smith in his *Catalogue Raisonné* enumerates no fewer than seven hundred. They possess, but in superlative degree, the qualities that mark his father's work. In the tone of his skies, the drawing of his trees, the animation and grouping of his figures, we see everywhere the presence of a richer, finer, more observant and more imaginative genius. None has realised more richly the charm of joyous open-air life. His scriptural subjects alone are unsatisfactory.

See also Kugler's *Handbook to the German, Flemish, and Dutch Schools*, remodelled by Waagen, rewritten by Crowe (1874).

Tenison, THOMAS, Archbishop of Canterbury, was born at Cottenham in Cambridgeshire, 29th September 1636, studied at Corpus Christi in Cambridge, and after holding several cures was made Bishop of Lincoln by William III. in 1691, and primate of all England three years later. He was a favourite at court, held many important state offices, and attended Mary and William on their death-beds. He crowned Queen Anne and George I., being a strong supporter of the Hanoverian succession, and died 14th December 1715. His works comprised some anti-papal tracts, sermons, and a criticism of Hobbes.

Tennant, WILLIAM, the author of *Anster Fair*, was born May 15, 1784, at Anstruther in Fife. A cripple almost from his birth, he naturally took to reading, and in 1799 went to the university of St Andrews, but was compelled to leave after two years to act as clerk to his brother, a corn-dealer. The business soon failed, and in 1813 Tennant was fain to accept the situation of parish schoolmaster at Dunino, near St Andrews, with a salary of £40 a year. The year before he had published his *Anster Fair*, a poem of much sprightliness and humour, notable as the first attempt to naturalise in our language the gay *ottava rima* of the Italians —soon after to be adopted with splendid success by Byron in his *Beppo* and *Don Juan*. A highly laudatory notice of the poem appeared in the *Edinburgh Review* in 1814, from the pen of the then omnipotent Jeffrey. In 1816 Tennant became a teacher at Lasswade near Edinburgh, whence three years later he was transferred to a mastership in Dollar Academy. His attainments as a linguist were extraordinary, and in 1835 he was appointed by the crown to the chair of Oriental Languages in the university of St Andrews. He died near Dollar, 15th February 1848. Tennant never equalled his first poem, although there was no little merit buried with the *Thane of Fife* (1822), *Papistry Stormed* (1827), and even the dramas of *Cardinal Beaton* (1823) and *John Baliol* (1825). See the memoir by Matthew Conolly (1861).

Tennemann, WILHELM GOTTLIEB, historian of philosophy (1761–1819), lectured at Jena, became professor at Marburg in 1804, and wrote, from the Kantian point of view, a *Geschichte der Philosophie* (vols. i.–xi. 1798–1819), and a shorter history (1812), translated as a *Manual of the History of Philosophy* (1852), long a text-book in Britain.

Tennent, SIR JAMES EMERSON, born in Belfast in 1804, studied at Dublin, and after practising at the bar was sent to parliament in 1832. He first supported Earl Grey and then Peel, and was secretary successively to the Indian Board, to the government of Ceylon, to the Poor-law Board, and to the Board of Trade. He was made a baronet on his resignation of the last post in 1867, and died in London, 6th March 1869. He is best known for his great work on *Ceylon* (1859) and books of travels in Greece and Belgium.

Tennessee, one of the central southern states of the American Union, the twenty-ninth in area and thirteenth in population, is situated in the Mississippi Valley in 35°—36° 30′ N. lat. and 81° 37′—90° 28′ W. long. On the N. are Virginia and Kentucky, on the E. is North Carolina, on the S. are Georgia, Alabama, and Mississippi, and on the W. the Mississippi River separates it from Arkansas and Missouri. Its mean length is 385 miles, its mean width 109 miles; area, 42,050 sq. m. Politically the state is divided into East, Middle, and West Tennessee, and these sections may rudely serve as natural divisions in describing its surface and physical characteristics, though the variety presented in topography, geology, soil, climate, and the habits and occupations of the people represents the corresponding features of the states by which it is bordered. East Tennessee extends from the Unaka and Smoky Mountains, which form the eastern boundary of the state, to the crest of the Cumberland Plateau. It contains some of the greatest ridges of the Appalachians, and abounds in magnificent scenery. Between the eastern ridges and the plateau stretches a valley region about 100 miles in width, broken by minor elevations and depressions. This valley slopes gradually from the north toward the south, and has an average elevation of about 1000 feet. Along its western edge the plateau rises in a bold wall from 100 to 200 feet high. The tableland has a broad flat top covered in places, especially toward the north, with the superimposed ridges and peaks of the Cumberland Mountains. Its western edge has a ragged contour notched by numerous 'coves' and valleys. The southern end is divided into two arms by a deep gorge with perpendicular sides rising from 800 to 1000 feet above the valley. The Sequatchie River flows through this trough until, near the southern border of the state, it is absorbed by the Tennessee River, which, breaking through the eastern arm, follows the valley for a distance of 60 miles into Alabama. The river then turns, and breaking through the western arm re-enters the state after forming part of the boundary between Alabama and Mississippi. Between the Tennessee River in its northern course and the Cumberland Mountains is Middle Tennessee, presenting a varied landscape of mountains, plains, hills, and valleys. It may be described as an extensive elliptical basin surrounded by an elevated rim. Between the Tennessee and the Mississippi rivers lies the western division of the state. The narrow valley of the former river is skirted on the west by a ridge running north and south across the state. From this divide a rolling plain slopes towards the west, terminating in a steep bluff, beyond which are the alluvial bottom lands of the Mississippi.

Copyright 1892 in U.S. by J. B. Lippincott Company.

Nearly all the geological periods are represented to a greater or a lesser degree, from the ancient metamorphic rocks of the mountains in the east to the recent alluvium of the Mississippi River bottom. Silurian deposits predominate in the mountain-region and in the valley of Middle Tennessee. Surrounding this valley are different groups of Carboniferous rocks, and in the Cumberland Plateau is a part of the great Appalachian coalfield. The coal-measures occupy an area of 5100 sq. m., and the seams are of exceptional thickness. It has been estimated that the available supply of bituminous coal is at least equal to that of Pennsylvania. West of the Tennessee River broad strips of Cretaceous and Tertiary deposits cross the state parallel to the alluvial bed of the Mississippi. The deposits of iron ore in different parts of the state are practically inexhaustible; copper and zinc are found, and the beautiful marbles are widely celebrated. Several famous mineral springs are the resorts of invalids. The soils of the state are fertile, and the forests of hard-wood timber constitute a great natural source of wealth.

The climate is mild and delightful, but marked by variety, which is due to numerous causes arising from geographical position and topography. The average length of time between killing frosts is 200 days. Herbage is often green throughout the year, and cattle generally graze during the winter months. The rainfall is ample, amounting to an average of 54 inches. The drainage of the state is ultimately received by the Mississippi. The Cumberland River, which enters the state from Kentucky, flows about 150 miles through the northern central part and then re-enters Kentucky. The Tennessee (800 miles), the largest affluent of the Ohio, formed by the union of the Clinch and the Holston, leaves the state and returns to it as has already been described.

Agriculture has been and still is the leading industry, but the mining of coal and iron and manufacturing are rapidly growing interests. All the cereals and fruits of the temperate zone flourish in Tennessee. The staple crops are corn, cotton, hemp, tobacco, and pea-nuts. The principal cotton districts are in the south-western corner of the state and in the southern part of the central basin. Stock-raising is extensively carried on. The production of pig-iron has greatly increased, and the number of factories for employing the raw material in the manufacture of machinery, agricultural implements, &c. has been proportionately augmented. There are also many cotton, woollen, flour, and paper mills, besides tobacco-factories and potteries. Within the limits of the state there are about 2700 miles of railroad.

Tennessee contains ninety-six counties, and returns ten members to congress. The most important towns are Nashville, the capital and largest city, Memphis, Chattanooga, and Knoxville. The state has a good system of public schools, with normal school instruction afforded from the proceeds of the Peabody fund, and there are many excellent private schools. The Vanderbilt University is at Nashville, and there are over twenty collegiate institutions in the state. The first permanent settlement was made on the Tennessee River, about 30 miles from the present site of Knoxville, in 1756. The early settlers asked and received the protection of North Carolina in 1776, and their territory was known as Washington county. In 1785 they organised the state of Franklin, and continued to dispute their rights with North Carolina till 1789, when the territory was ceded to the United States. In the following year territorial government was established, and in 1796 Tennessee became a state. It was the last of the southern states to secede in 1861, and the first to re-enter the Union in 1866. Pop. (1800) 105,602; (1850) 1,002,717; (1880) 1,542,359 (403,528 coloured); (1890) 1,767,518 (434,300 coloured).

See Histories by Ramsey (Phila. 1860), Carpenter (Phila. 1863), and Phelan (Boston, 1889); and Thruston's *Antiquities of Tennessee* (Cin. 1890).

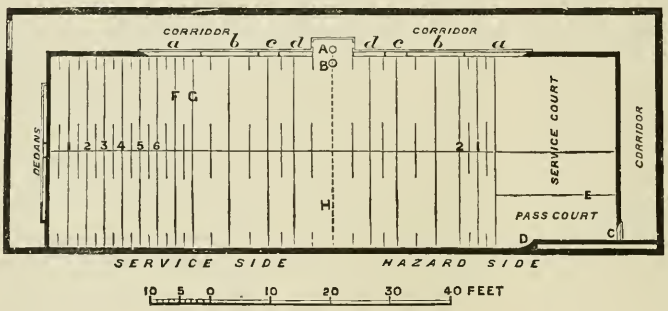
Tenniel, Sir John, caricaturist, was born in London in 1820. A self-trained artist, he was selected in 1845 in competition to paint one of the frescoes—Dryden's 'St Cecilia'—in the Houses of Parliament. But to the public he is known not as painter, but as book-illustrator, and chiefly as the cartoonist of *Punch*. He joined its staff in 1851, and year after year since Leech's death produced the principal weekly political cartoons for *Punch*, which are notable not less for their pathos than for their wit, humour, and skilful draughtsmanship. His illustrations to *Alice in Wonderland* and *Through the Looking-glass* are

remarkable for their grace, delicacy, and finish; earlier book-illustrations were to *Æsop's Fables*, Moore's *Lalla Rookh*, the *Ingoldsby Legends*, &c. He was knighted in 1893; and published his last cartoon in *Punch*—last of the fifty years series—in January 1901.

Tennis is descended from a handball game (*longue paume*) played in the *fossés* of French and Italian châteaus in the middle ages. By the 14th century enclosed courts were common in France, and shortly afterwards some form of racket was introduced, but the prototype of the modern implement was of so elementary a character that another century elapsed before it superseded hand play. The numerous allusions to tennis found in English literature, from Chaucer onwards, prove that it has been played in England since the 14th century. It was the favourite pastime of several of the kings, and at one time became so popular that laws were passed prohibiting it. The expense of building and keeping up a court has confined the game to the aristocracy, but the fact that nearly a dozen courts were built during 1881–91 proves that it is by no means out of favour.

Scarcely two courts in existence are identical in all respects; the dimensions given below are therefore taken from the typical court in Mr Marshall's *Annals of Tennis*. The dedans and corridor are covered by a sloping wooden roof, 7 feet 2 inches from the floor, called the penthouse. The dedans, galleries, and grille are openings in the wall below the eaves of the penthouse. The net is 3 feet high at the centre, 5 feet at the sides. The racket consists of a strong hoop of ash tightly strung with black gut, with a wooden handle, the whole being 2 feet 2 inches long, and weighing about 16 oz. The ball is made of woollen material covered with white cloth, and weighs 2½ oz. A set of six dozen balls is in use at one time, and a set will last fifty years or more if re-covered and moulded into shape from time to time.

The game may be played by two or four players. The server stands anywhere on the service side of the court and strikes the ball, so that it drops in the service-court after first touching the side penthouse. The striker-out must return it over the net either at the volley or first bound. A player scores a stroke (1) when he hits the ball into a winning hazard, viz. dedans, grille, or last gallery on the hazard side; (2) when his opponent hits the ball into the net, out of court, or loses a 'chase.' The latter term requires some explanation. When a ball falls—i.e. touches the floor for the second time—on or between any of the lines marked across the court, or enters any of the galleries except the winning gallery, the marker calls out 'chase six,' 'second gallery,' 'better than two,' according as it falls 6 yards from the end wall, in or opposite the second gallery, or between the 1½ and 2 yard lines. When two chases have been made, or one if either of the players is within a stroke of the game, they change sides, and if the striker-out succeeds in making the ball fall nearer the end wall than his opponent had done, he wins the chase. If he makes the same chase it is called 'chase off,' and the score is not affected. When a player wins a stroke the score is called '15—love.' His next stroke brings him to 30, then 40, then game. Thus four strokes may win a game, but if both players reach 40 the game is called 'deuce,' and it is necessary to win two strokes more in succession to secure the game. A 'set' is the best of eleven games. The origin of this method of scoring is doubtful. The most obvious explanation is that in French courts there were fourteen chases, and so they began scoring at 15 to avoid confusion; but there seems to be conclusive evidence that this system of scoring was introduced before chases were in use.

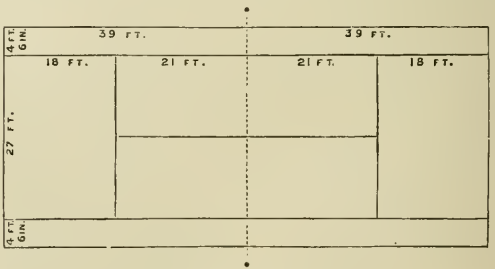


Plan of Tennis Court:

a, *a*, last gallery; *b*, *b*, second gallery; *c*, *c*, doors; *d*, *d*, first gallery. A, marker's box; B, basket for balls; C, the grille; D, the tambour; E, pass line; F, chase, last gallery; G, chase, a yard worse than last gallery; H, net.

Lawn-tennis, though the offspring of tennis, quickly surpassed her parent in importance; she has even usurped her name. The prescriptive right of centuries is of no avail against the fiat of the people, and now probably 99 per cent. of those who use the word tennis refer to the younger game. Major Wingfield is generally credited with the invention of lawn-tennis in 1874, and perhaps he had more to do with its introduction than any one else. His 'sphairistiké' was a compromise between tennis and badminton, and in principle—viz. hitting a ball over a net into a space marked out on a lawn—was identical with the lawn-tennis of the present day, but most of the details have been altered. The tendency of the age is towards increased pace in all things, and lawn-tennis is no exception to the rule. The net has been lowered from 5 feet at the sides and 4 feet in the middle to 3 feet 6 inches at the sides and 3 feet in the middle. The balls have become more lively, the rackets more tightly strung. The result of these developments was to give the server a great advantage, and this had to be obviated by bringing the service-line nearer the net—from 26 feet to 21 feet.

The tactics of the game have altered no less than the implements. In early days play was confined for the most part to the back of the court, then it was found that a volley at the net was a deadly form of attack; but it is now generally recognised that both for the single and double game the service-line is the strongest position to occupy, as from here it is easy to run forward to kill a ball by a 'smash,' or retreat when it is necessary to get



Plan of Lawn-tennis Court.

back a severe stroke of the opponent or return a 'lob.' The game is usually played on grass, the lines being marked out with 'whiting;' but asphalt, cinders, and various other substances have been tried, and covered courts with wooden floors enable it to be played in wet weather. The racket should weigh from 14 to 15 oz.; for ladies, 12½ to 13½ oz. The balls are made of hollow india-rubber, covered with white cloth, and weigh 2 oz.

All legislation relating to the game is now in the hands of the Lawn-tennis Association. The inner court, 27 feet wide, is used for the single game, the 36-feet court when four are playing.

The name *tennis*—also formerly spelt *tennise, tennys, tenys, tennes*, &c.—would appear to be of old French origin; but no such old French name for the *jeu de paume* has been discovered. The long-accepted etymology—that the name comes from a presumed cry of *tenez*, 'hold' or 'take,' is apparently quite baseless. The palmy period of the old game—*le roi des jeux et le jeu des rois*, as it was called—lasted in France till the time of Louis XIV. The most historically famous tennis-court was that of Versailles, in which the French National Assembly met in 1789. The old game is sometimes called *court-tennis* to distinguish it from lawn-tennis. RACKETS (q.v.) and FIVES (q.v.) are cognate games.

See the Badminton Library book on *Tennis, Lawn Tennis, Racquets, and Fives*, by J. M. and C. G. Heathcote (1890); the *Annals of Tennis* (1878), and *Tennis* (1889) by Julian Marshall; and works on Lawn Tennis by 'Cavendish,' Brownlee, Crawley, Dwight, Peile, Smythe, Wilberforce, and others.

Tennstedt, a Prussian town 15 miles NW. of Erfurt, with a sulphureous spring; pop. 3100.

Tennyson. ALFRED, LORD TENNYSON, was born on August 6, 1809, at Somersby, a little village among the wolds of Mid-Lincolnshire; rector of which was the poet's father, Dr George Clayton Tennyson; his mother, Elizabeth Fytche, being also of a Lincolnshire family. Dr Tennyson was a man of marked physical strength and stature; accomplished in fine art, music especially, and in language; in temperament imaginative, verging at times upon gloom. These conditions, more or less, reappeared in his family. Johnson's pretty phrase about his own college, 'a nest of singing birds,' might be applied to the Somersby parsonage. Alfred was third of seven sons; amongst whom his two elder brothers, Frederick and Charles, became notable as poets. Frederick Tennyson in 1854 published *Days and Hours;* in 1890, the *Isles of Greece;* in 1891, *Daphne and other Poems*. A notice of Charles (Tennyson) Turner will be found in its place. To the latter Alfred was devoted with a child's warm love and reverence, which break forth tenderly in the *In Memoriam*, and later in the *Midnight* of June 30, 1879. Charles, whilst both were little, 'gave him a slate, and bade him write some verses about the flowers in the garden.' The slate was soon covered; Charles read the lines, and gave them back with a 'Yes, you can write.' Some ten years later, *Poems by Two Brothers* (1826) witnessed to that profound early union of heart and soul between Charles and Alfred. Of this little book it will be enough to say that it shows, even if imitatively and immaturely, wide range in subject and varied command of metre. Already in fact, at thirteen or fourteen, Alfred had written a long epic, of which Dr Tennyson, an excellent and well-read scholar, said: 'If that boy dies, one of our greatest poets will have gone;' a paternal prophecy the fulfilment of which perhaps justifies its preservation. Byron at this time was the leading modern favourite of the brothers. At the fatal news from Missolonghi (April 1824) the world seemed at an end to Alfred, who, boylike, commemorated the event by carving upon a sandstone rock—*Byron is dead*.

Copyright 1892 in U.S. by J. B. Lippincott Company.

As the landscape of Warwickshire has been traced in Shakespeare's early work, so in Tennyson's appears that of Lincolnshire; a county far more picturesque than many fancy, in its great contrasts of hill and level, wold and fen. Here was his earliest education through the most susceptible years of life. Near Somersby is Louth, where the brothers found their classical school; near also, Horncastle, where grew up meanwhile for Alfred the hope of youth, the blessing and mainstay of after years.

In February 1828 the 'two brothers' joined Frederick at Trinity College, Cambridge, finding presently a group of friends among whom many fulfilled the promise of their May: J. Spedding, J. M. Kemble, W. H. Brookfield, R. C. Trench, R. M. Milnes, C. Merivale, H. Alford, E. Lushington; and, above all (October 1828), Arthur Henry (born Feb. 1811), eldest son to Henry Hallam, the great historian. Early as he was lost (September 1833), sufficient proof exists that the commanding influence which the youthful Arthur held over his most gifted contemporaries, in that golden day of English youth; that the pictures of the past and anticipations of the future set forth by Tennyson in the famous memorial poem—all were fully justified by his singular ability, by his depth and tenderness of thought, by his beauty of nature. In this genial atmosphere Tennyson's genius rapidly advanced. To this time belong *The Lover's Tale* (written 1827, published 1879), a blank verse rhapsody, and *Timbuctoo*, the poem (also in blank verse) by which he gained the university prize of 1829. Both pieces in general colour and in single phrases anticipate the style by which Tennyson presently became (and remains) known to us: he has already left the prelusive attempts of early youth; he has fairly found himself. After the appearance of *Timbuctoo*, A. Hallam wrote: 'I consider Tennyson as promising fair to be the greatest poet of our generation, perhaps of our century.'

His father's death broke off Tennyson's Cambridge residence early in 1831. In the autumn he made that visit to the Pyrenees recorded in the beautiful *All along the valley*. Meantime his first published volume, *Poems, chiefly Lyrical*, had appeared (1830), followed by a similar small series in 1833. 'That greatest of persecutions, Silence,' has never been our poet's fate; he was now pelted and praised, misjudged and rightly judged—the common lot. But he turned to profit friend and enemy, dropping many less mature pieces, steadily studying and practising an art in which supreme excellence is never dissociated from intensity of labour: poor, and under the cloud of grief for the friend who had passed away in Vienna, 'and beloved of the gods.' To these nine years, spent partly in Lincolnshire, mostly in London, we owe many of his most lovely lyrics; some, the subjects of which were reworked or much expanded in later years. Together with the best of his earlier work, these were published in 1842. Henceforth his place was secure. 'He is decidedly the first of our living poets,' wrote Wordsworth in 1845, 'and I hope will live to give the world still better things.'

1847 brought *The Princess: a Medley*, or melodrama, we might say, written in blank verse, almost lyrical in its music; gay and fanciful as *The Midsummer Night's Dream* in plot, yet with the seriousness of life in its underlying chivalrous moral.

Should we say that to 1850 Tennyson might

look back as his *Annus Mirabilis?* This year, at least, in succession to Wordsworth, brought him the laureateship; and in this fell the publication of *In Memoriam*, that elegiac treasury in which the poet has stored the grief and the meditation of many years after his friend's death; a series of lyrics which in pathos, melody, range of thought and depth of feeling may stand with the *Canzoniere* of Petrarch and the *Sonnets* of Shakespeare. But that early widowhood of love was now happily closed (June 13) by the marriage—to which the poet, and we with him, may we not add? owe so much—with Emily Sellwood, in Shiplake Church, Oxfordshire.

Tennyson and his wife now settled at Twickenham. In 1851 they went through the Riviera to Florence, returning by Milan. In 1852 Hallam, his eldest son, was born; the great funeral Ode upon Wellington was written. By the close of 1853 the passion for his old country life, freedom and peace, and fair English scenery, carried him to Farringford in Freshwater. There Lionel was born (1854); and there, with Sir John Simeon as his highly prized neighbour, and frequent brief journeys interspersed, Tennyson lived uninterruptedly till 1870; having built meanwhile a house for summer and autumn residence (Aldworth), high up on the farther side of Blackdown by Haslemere: at once nearer London, and farther from that intrusion which is one of the penalties paid for fame. Some of these journeys may be recorded; they form no unimportant part of a poet's tranquil life. They included the Western Highlands, Staffa and Iona (1853); Inveraray (1858), to visit the Duke of Argyll, another much-valued friend; Portugal (1859); Cornwall (1860); the Pyrenees again (1861); Derbyshire and Yorkshire (1862); Weimar and Dresden (1865); Dartmoor and Salcombe (1867); North Wales (1869).

Lyrical poetry pure—free from divergence down those 'two byways' (as Schiller named them), the didactic and the rhetorical—in perhaps every one of its forms, had been now set forth by the poet: the lyric of melody, of passion, of description, of travel, of incident, of reflection; the ballad, the personal song, the elegy, the national ode. And the idyll—'that little picture' which has a natural but not exclusive affinity with country life and narrative gently suffused with passion—was also included. It remained for the poet to carry further these modes of song, and to add in particular the drama proper, with the humorous monodramatic presentation of character in rustic forms of speech.

In *Maud: a Monodrama* (1855), Tennyson has given to the personal lyric (for *In Memoriam*, strictly speaking, is elegiac in movement) its deepest and widest extension. As with Hamlet, a taint of mental distraction is supposed to affect the narrator and hero of the drama; leading him to over-colour, through the light of personal feeling, his pictures of the world about him, the politics and manners of the time; whilst the same stress of nature has raised the songs which paint his love-story, in its triumph and its despair, to a sevenfold fire of passionate melodious beauty. Lyrical poetry, unless it were among the Æolic singers of early Greece (so far as the writer knows), has attempted no such scheme as that presented by *Maud;* and the poem may perhaps in popular estimate have suffered the penalty which thoroughly original treatment seldom escapes.

As *Maud* extends the domain of Tennyson's lyrical work in depth of feeling, variety of subject, and area traversed by the narrative, so that 'small picture,' the idyll, epic and historic, tale and character-picture, was treated by him henceforth. To this enlargement witness first the *Enoch Arden* and *Aylmer's Field* of 1864. The poet's power had reached full maturity; his art was perfect. He now took up seriously that Celtic legend which, lacking adequate Teutonic material, England for eight centuries has welcomed as her national epic—our old Arthurian story, to which he had preluded already by a few beautiful sketches; and in 1859 appeared the first four of the twelve *Idylls of the King*, completed by instalments in 1870, 1872, 1885.

Spread thus over more than a quarter of a century, this is the poet's most important, probably his greatest work. Space fails here to do more than indicate the misty, much-debated origin, and development of the romance of Arthur. At first the real Prince, or Gwledig, defeating his foes in the old Welsh kingdom of Strathclyde, perhaps about 500 A.D.; his figure then goes through some centuries of obscurity, reappearing by the middle of the 12th, first as a European conqueror in Geoffrey of Monmouth; then presently in his mythical aspect, possibly confused with some pagan divine hero, Lord of the Round Table; finally passing to Avalon, *rex futurus*. From that time the tale spread like wildfire over Europe, and soon after 1200 Arthur's name and deeds were celebrated in many romances, English, Welsh, French, German, even Icelandic; collecting about him other scattered Celtic legends, notably that of the *Grail* (see note at end of this article). Malory lastly, that 'most unintelligent compiler' (A. Nutt, *Studies on the Legend of the Holy Grail*, 1888), but gifted with an admirable style, selecting from the vast mass of material, framed, treating it freely in the manner of his day, the *Morte Darthur* (published by Caxton 1485); whence Tennyson has taken, again varying them, most of his legends: that of Geraint and Enid, from Lady C. Guest's admirable translation of the Welsh *Mabinogi*, being the chief exception.

Picturesque as the old story however became, throughout its many modifications of five centuries and more, it could hardly have been lifted above a poetic-antiquarian interest for Englishmen generally, were its early tone and quality and adventures repeated in modern verse, however skilful. This difficulty has been felt before with regard to our own and other mediæval romances. Ariosto by skilful serio-comic treatment gave a vitality which is now well-nigh exhausted to the legends of Charles. Spenser turned Arthur and his knights into an allegory, with constant allusion to Elizabethan times. And similarly that *quidlibet audendi potestas* which Horace with absolute right claimed for the poet has been everywhere exercised by Tennyson in the *Idylls*. Throughout they are interfused with the vital atmosphere of the Victorian age; and by no other mode could the king return, as it were, and live again in the hearts and souls of men. The fitness of this great change, which presents Arthur not as noble, guilty, and repentant, but as noble, blameless, self-restrained, and far-sighted, is of course fairly debateable. Tennyson has throughout imaged the king as he appeared to the old Welsh historian: 'God has not made, since Adam was, the man more perfect than Arthur.' Nor is it easy to see how the needful central figure for the Arthurian epic, as imagined in its unity by Tennyson, a figure at once human and ideal, could otherwise have been presented; although whether in his picture the delicate balance has or has not been kept may perhaps long remain a fit subject for critical declamation.

The noble *Dedication* (as indeed was already noted in the prelude to the *Morte d'Arthur* of 1842) sets forth the main underlying intention of the *Idylls*. They are a 'new-old' tale, 'shadowing

Sense at war with Soul;' the individual conscience with its innate aim towards truth and purity; its temptations, falls, and conquests; its final victory, discovered only in the true life which follows our brief breathing space upon earth. This inward conflict is displayed under the guise of the legend how Arthur, through the Round Table (that late mediæval picture of imagined chivalry), the knights and ladies of the court, tries to lead a crusade on behalf of a perfect civilised Christian state; how also, through the sins and selfishness of his followers, the fair Utopia is here never realised. It is a tale, not a mere allegory, although allegory be occasionally introduced; the persons, each in turn, are the mixed human characters of all times, whilst one clearly defined quality figures some bias or aim which dominates the life of each, working evil or good for himself and his fellow-creatures. Jealousy marks Geraint; woman's longsuffering patience, Enid; in Elaine we have pure passionate devotion, cast away by Lancelot in favour of guilty love for Guinevere; in Percivale and Galahad, ideals of a devoted holiness, souls of whom the world is not worthy, and who have little place in its struggles, yet whose example the world could not afford to miss. But we narrow and harden by such definitions the rich flexible vitality of Tennyson's Titianic picture, with its endless touches of light and shadow, its breadth and liberality of varied palpitating colour; the modulations (to take another figure) through every key of passion and character, the ever-present yet ever-appropriate melody of the metre. But, more fortunate than the musician, the score of the poet's symphonies is not only in the reader's hands, but, according to his faculty, he may reproduce the music for himself:

> Heard melodies are sweet, but those unheard
> Are sweeter.

Arthur, *rex quondam, rexque futurus* (as we may believe) for many generations, has been thus set before us in our British epic. Small, however, is the element of probable fact in that ancient legend. It was hence, perhaps, natural that a poet-laureate, who, like his great predecessor, feels for England 'as a lover or a child,' should attempt to deal with the realities of our magnificent history. Add that in many pieces, monodramatic in form, Tennyson has shown brilliant power to create character, seriously presented or with admirable humour, and that he has also been ever bold to enlarge the bounds of his art. Thus three plays, spread in subject over some four centuries, have been the result—*Queen Mary* (1875), *Harold* (1877), *Becket* (1884). And with these, certain less important dramas may be named: *The Cup*, founded on a Graeco-Roman tale; *The Promise of May*, a modern domestic piece; *The Foresters* (1892), the poet's own version of the Robin Hood legend.

Dramatic art is, however, hampered by many peculiar laws and limitations; nor is the close air of modern civilisation favourable as that of the 16th and 17th centuries to the poetical drama. Nor, again, does the highest gift for character or incident-drawing carry with it necessarily the power to put incident into dialogue, or to make the most of dramatic situations suitable to the theatre. Even Scott, with his Shakespearian invention, and also eminently effective when the persons in his novels speak together, yet failed when he attempted the stage; nor can Goethe or Byron be credited with better success. And, similarly, no play of Tennyson's hitherto acted (unless with exception of *The Cup*) has (in England, at least) reached definite popular acceptance. The time, in truth, to estimate their spectacular value has not yet arrived. But that they form a noble contribution to our history may, we hold, be considered certain.

A few more volumes, idylls, lyrics, ballads, remain (1880, 1885, 1886, 1889, 1890). Compared with much of Tennyson's earlier work, these, in general, reveal a more mature and certain art, a greatly wider range. History (mostly English); tales in dialect, chiefly that of Lincolnshire; a few beautiful classical pieces; narratives, idyllic and lyrical, of the profoundest pathos; poems treating great problems in religion and morality, philosophy and science—all, with other 'fresh fields' which we have not space to name, are included. The more decoratively imagined art, frequent in the poet's youthful verse, has now, by natural law, given place to art, not less finished, but deeper, often darker, in thought. If, compared with *In Memoriam*, a gloomier scepticism is allowed to speak, faith reaches a sweeter and surer creed. Titian, in a word (and our last), has made way for Rembrandt.

A few personal notes, however, must be added. Before advancing years restrained, without seriously injuring, his activity, Tennyson, in 1876, once more visited the Pyrenees; in 1878, Ireland; 1882, Lombardy; 1883, Copenhagen; 1887, St Davids and the Channel Islands; 1891, Devonshire.—The losses and the gains of prolonged life he was called on to experience. Besides many among the band of earlier friends, his brother Charles was taken in 1879; his younger son Lionel, after an honourable career in the public service, in 1886. Hallam, the elder, married Audrey Boyle, grand-daughter to Admiral Hon. Sir Courtney Boyle, one of Nelson's captains, in 1884. And several children of the brothers renewed the charm and sunshine of youth to Aldworth and Farringford. In 1884 Her Majesty, recognising even more than conferring honour, created a barony of the United Kingdom by the style of Tennyson of Freshwater and Aldworth, in favour of her poet-laureate. Lord Tennyson died at Aldworth on the 6th October 1892, and was buried in Westminster Abbey.

For detailed criticism this is neither the place nor the time. Natural it is, indeed, to ask what, when a century or more has gone by, will be Tennyson's rank in the hierarchy of Parnassus? But of this 'the days to come will be the wisest witnesses.' Even were it possible now to estimate the absolute value of his whole work, two weighty and inevitable determinants of future fame are absolutely beyond foresight—namely, What near successors any man is fated to find—the question, whether or not, as Dante observed, a Giotto shall follow a Cimabue, and 'have the cry' and obscure his fame:—And what will be the career (upward or downward, folly alone would affect to decide) of the world's civilisation. Some slight general hint, however, as resting on grounds which no one is likely to dispute, may be risked in regard to Tennyson's general relation to his five great British predecessors during the first half of the century—Scott, Byron, Keats, Shelley, Wordsworth—remembering also that among these only the first and the last reached the 'mezzo del cammin di nostra vita.' And this suggestion we shall express after the terms employed by the great critic Quintilian when giving his reasons to place Virgil at the head of Latin poetry. If there be certain gifts of genius wherein Lord Tennyson yields to those illustrious contemporaries of his youth, each in his turn, it is beyond question that during his many years he has written with more constant, more equal *cura et diligentia;* that his mastery of his sublime art has been more perfect; that in range and command of varied subject he has been unequalled.

Among the later volumes were *The Lover's Tale* (1879), *Ballads, &c.* (1880), *Tiresias* (1885), *Locksley Hall—Sixty Years After* (1886), *Demeter* (1889), *The Death of Œnone, Akbar's Dream, and other Poems* (posthumous, 1892).

Tennyson's keen and abiding interest in religious and ethical problems is shown throughout his work; his fervid patriotism was conspicuous at all times, and he took his side unhesitatingly in the great political issues of the day. Long before colonial federation was popular he wondered England could not see that 'her true policy lies in a close union with our colonies.' In his personal friendships, as in his literary tastes, he was unusually catholic. Amongst his friends he ranked Carlyle as well as Gladstone, and Huxley as well as Ruskin. He loved to read aloud Shakespeare, Milton, and Chaucer; he reverenced Wordsworth; said that Keats, if he had lived, 'would have been among the very greatest of us;' thought Goethe among the wisest of mankind as well as a great artist; and in his friend Browning recognised a mighty intellect, 'though he seldom attempts the marriage of sense with sound.'

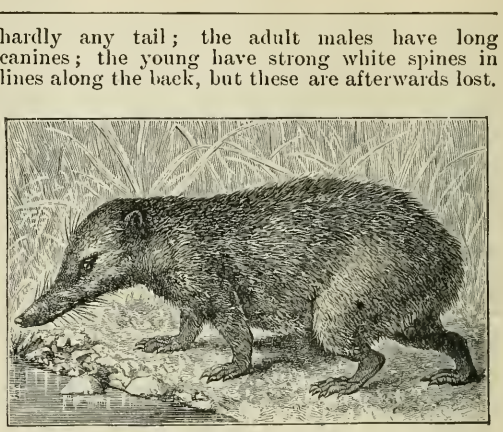
The authoritative biography, by the second Lord Tennyson, appeared in 1897. See also other books on Tennyson and his works by Wace (1881), Van Dyke (5th ed. 1896), Tainsh (1868; new ed. 1893), Jennings (1884; new ed. 1892), T. Davidson (Boston, 1889), Churton Collins (1891), Eugene Parsons (Chicago, 1891), A. Waugh (1892), Ritchie (1892–93), Jenkinson (1892), Jacobs (1893), Stopford Brooke (1894), and Bellezza (Italian, 1894); besides essays and criticisms, of which a list will be found in R. H. Shepherd's *Tennysoniana* (1866; new ed. 1879; bibliography separate, 1896). The article by Canon Ainger in the *Dictionary of National Biography* (1898) deserves special mention; also Mrs Richmond Ritchie's *Records of Tennyson, Ruskin, and the Brownings* (1892). There is an analysis of *In Memoriam* by F. W. Robertson (1862); a *Key* to it by Dr Gatty (1881; 4th ed. 1891); a *Concordance to Tennyson* by D. B. Brightwell (for the works up to 1869); a *Tennyson Handbook* by Morton (1895), and a *Tennyson Primer* by Dixon (1896). See also A. J. Church's *The Laureate's Country* (1890), J. C. Walters's *In Tennyson Land* (1890), G. G. Napier's *Homes and Haunts of Alfred Tennyson* (1892), and B. Francis's *Scenery of Tennyson's Poems* (1893). Many of the poems have been translated; of *Enoch Arden* there are nine German versions, seven French, and two Dutch, as well as Italian, Spanish, Danish, Hungarian, and Bohemian. For the basis of the Arthurian poems, see ARTHUR, GRAIL.

The second LORD TENNYSON (born 1852) was educated at Marlborough, Trinity College, Cambridge, and the Inner Temple, and acted as his father's private secretary. He contributed to the magazines in prose and verse, edited Charles Turner's *Collected Sonnets*, edited the *Poems by Two Brothers*, and wrote the definitive memoir of his father (2 vols. 1897). In 1899 he was appointed Governor of South Australia.

Tenor, in Music, is the higher adult male chest voice (see VOICE, p. 501). The tenor clef (a C clef on the fourth line of the stave) is now little used, the music being usually written an octave above its real pitch, on the treble clef. In early church music the tenor part was the melody.

Tenos, or TINO, a Greek island in the Archipelago (q.v.), belonging to the Cyclades, is 18 miles long, 70 sq. m. in area, and has a pop. of 12,565. The capital, Tenos, on the south coast, has 2083 inhabitants.

Tenrec (*Centetes*), a genus of Insectivora, represented by one species (*C. ecaudatus*), which is restricted to Madagascar, Bourbon, and Mauritius. It is the largest known insectivore, measuring from 12 to 16 inches in length; and it is probably the most prolific of mammals, since as many as twenty-one young are said to have been brought forth at a birth. The body is squat; there is hardly any tail; the adult males have long canines; the young have strong white spines in lines along the back, but these are afterwards lost.



Tenrec (*Centetes ecaudatus*).

It feeds chiefly on earthworms, and is said to become dormant during the hottest part of the year.

Tent (Lat. *tentus*, 'stretched,' from *tendere*). Tents have been used since very early times as an advance upon cave-dwellings, especially amongst nomadic tribes. The skins of animals, or leaves, or bark formed the earliest coverings, textile fabrics being substituted as civilisation advanced. Bible patriarchs always dwelt in tents, probably much the same as the modern Arab tents, which are large structures, very rude in form and of small height, but covering a considerable area. The covering is felted goat-skins. The Jewish Tabernacle was a large tent, and had a covering of rams'-skins and badgers'-skins (new translation, seal-skins). The Nineveh sculptures show the tent of King Sennacherib, like modern tents supported by ropes. The manufacture of goatskin tents was an established industry in the time of St Paul, who took part in it. The early Greek tents were made of skins, each accommodating two soldiers. Alexander the Great is said to have had a pavilion of extraordinary magnificence. Its roof, one mass of gilded embroidery, was sustained by eight pillars covered with gold. In the centre was the royal throne; and 100 beds could be made up within the temporary edifice. The Roman tent was made of canvas or some such material, supported by two upright posts carrying a ridge pole. Each held ten soldiers with their *decanus* or corporal. In Persia many tribes live entirely in hemispherical felt tents much decorated and with handsome door hangings. Chinese tents are usually of matting, of great size, and often very comfortable. The American Indians' wigwam is a conical tent of bark, mats, or skins on poles; and the so-called wigwams in which the thousand delegates of one of the American political parties sometimes meet, as at Chicago in 1892, are simply enormous tents. The tents of Gypsy tent-dwellers are stretched on rods bent into hoop shape. Like canoeing and caravaning, camping out in tents is a popular way of holidaying for healthy young men not unwilling to rough it a little; see Lowndes, *Gypsy Tents and how to use them* (1890); Macdonell, *Camping Out* (1892).

Except in tropical or very inclement climates tents are not carried by European armies now in any large numbers. Troops are billeted in villages or bivouacked. A few tents for the senior officers, for offices, guards, and hospitals are provided in the equipment of British troops operating in Europe, and in peace manœuvres a sufficient number is provided for all ranks. In India too this provision is always made. The European

tents generally used are three in number: the *hospital marquee*, dimensions 30 feet long, 15 feet broad, and 15 feet high; sides, 5 feet high; has two poles; weighs in its valise with poles, four large and 180 small pins, and two mallets —512 lb. dry, 660 lb. wet. It accommodates ten sick in beds or sixteen without. The circular *bell-tent* has a diameter at the base of 12½ feet, and is 10 feet high, taking sixteen men, and weighs about 74 lb. dry, 90 wet. The pole is in two pieces like those of the hospital marquee, and forty-two pins with two mallets go with each tent. Both these tents may be floored with wood or tarpaulin, and if the interior is dug out are much more commodious. They are made of sail canvas. The *tente d'abri*, or *shelter tent*, consists of two sheets, two poles, and seven pins; weighs 11 lb. dry, 16 lb. wet; and takes two or three men lying down. Each carries a part of the tent. They were used in the Nile expedition of 1884. In India a large double-roofed square tent is always used, the upper roof projecting so as to form verandas. The sides are vertical and 5 feet high, kept rigid by short poles, and there is one large pole in the centre. Each accommodates sixteen soldiers or twelve sick. The Durbar tents of the Indian government are very large and beautifully made. Those used by the government officials are also much more commodious than ordinary tents.

Tentaculites, a genus of annulated tapering shells, found abundantly in Silurian and Devonian strata. Their affinities are somewhat obscure. By some writers they are regarded as tubicolar annelids, while others refer them with some hesitation to the pteropoda.

Tenterden, a municipal borough and market-town in the Weald of Kent, 13 miles SW. of Ashford and 7½ S. by E. of Headcorn station. The church has a noble Perpendicular tower, built in the 15th century, and associated by legend with the Goodwin Sands (q.v.). Pop. (1851) 3901; (1891) 3429.

Tenterden, Charles Abbott, Baron, was born a barber's son at Canterbury, 7th October 1762. A foundationer at King's School, Canterbury, of which he was captain at seventeen, he gained an exhibition which enabled him to proceed to Corpus Christi College, Oxford. Here he obtained a scholarship; in 1784 the chancellor's medal for Latin verse, in 1786 for an English essay; graduated in 1785, and soon after became fellow and tutor of his college. Entered at the Middle Temple, he was called to the bar by the Inner Temple in 1796. He joined the Oxford circuit, and, in spite of a husky voice, a heavy face, and timid manners, his energy and knowledge soon brought a large practice. In 1801 he became recorder of Oxford, and next year published his clear and learned treatise on the *Law relative to Merchant Ships and Seamen*. It had the effect of increasing his employment in the more lucrative mercantile causes, so much that in 1807 he returned his income as upwards of £8000. In 1816 he accepted a puisne judgeship in the Court of Common Pleas; and in 1818 he was knighted, and chosen to succeed Lord Ellenborough as Chief-justice of the King's Bench. As a judge his most marked characteristic was his perspicacity and freedom from bias. He was raised to the peerage in 1827. In the House of Lords he strongly opposed the Catholic Relief Bill, and in his last speech he made a vow that if the Reform Bill, that 'appalling bill,' passed, he would never again take his seat as a peer. He fell ill at Bristol, while presiding at the trial of the mayor for misconduct during the Reform riots, and died suddenly, 4th November 1832.

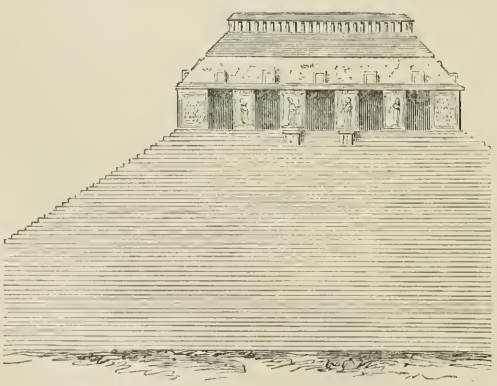
Tenure, a general name for the conditions on which land is held by the persons who occupy and use it. Forms of land tenure are of various kinds; the earliest of them are connected with the occupation of a tract of country by a tribe or village community; with the advance of civilisation individual rights were more precisely defined; under the Roman law land was a thing *in commercio*, to be used and disposed of at the discretion of the owner. The feudal system combined something of the precision of Roman law with the personal tie between lord and vassal as recognised in the customs of the barbarian nations. Rights in land were made the basis of social order; every man rendered definite services to the superior of whom he held. The Norman Conquest brought in a race of expert lawyers who would have carried feudal theory to an oppressive extreme if it had not been for the principles recognised in Magna Charta and afterwards embodied in legislation. All lands in England were, and still are, held of the crown; the actual owner or cultivator of the soil owed suit and service to the king or to some subject lord who held of the king. The Manor (q.v.) was the unit of administration. The tenures recognised by law were of three kinds: (1) Military tenures, such as knight-service, the chief incidents of which were the duty of serving in war, suit of court (attendance in the courts of the superior), aids, reliefs, and primer seizin (money payments on certain occasions), and escheat (reversion of the land to the lord on failure of heirs, &c.). The lord exacted a fine on alienation of the holding; he had the wardship of an infant heir, and as guardian disposed of his hand in marriage. These tenures were extremely burdensome, and the feudal rights of the crown were greatly abused. At the restoration of Charles II. the military tenures were abolished, except only the honorary services of Grand Serjeanty (q.v.). (2) Free socage—the service of freemen who rendered fealty and suit of court, together with some fixed service, such as might be, and always was, commuted for a payment in money. This is the tenure on which freehold lands are still held. (3) Copyhold, the tenure of persons who originally were villeins or villagers holding at the will of the lord, but had gained a more secure position by the custom of the manor, and held copy of the court rolls on which their rights were recorded. Land assigned for the endowment of the church was held 'by divine service' or by the still easier tenure known as *frankalmoign* or free alms. In process of time feudal ideas of social order gave way to commercial ideas; land was regarded merely as a form of property to be used and disposed of at the discretion of its owners. Thus, though tenure still exists in England, it is of comparatively small importance. The distribution and management of land are governed by contract, not by feudal rule. Economists and lawyers hold for the most part that 'free trade in land' is justified by its results; Sir H. Maine points to the rapid settlement of North America as a sample of what can be done by men stimulated by the hope of acquiring property. Socialists and land-nationalisers hold that property in land is the cause of an unjust distribution of wealth; they would take all land (with or without compensation to existing owners) into the hands of the community, and they would permit no tenure except on such terms as the community might consider to be advantageous.

In Scotland, as in England, the feudal system was long established. Subinfeudation (grant of land by a free vassal to another person to hold under himself) has been forbidden in England since 1290, because it was found to prejudice the rights of superior lords; but the practice was permitted

in Scotland. Modern Scots law distinguishes between the property or *dominium utile* of land and the superiority or *dominium directum*, the chief incident of which is the feu-duty paid by the vassal. On alienation of the land or death of the vassal forms were used implying consent or recognition by the superior, and casualties or additional payments were made on such occasions. These forms and the endless creation of subordinate feudal rights tended to complicate the whole system of conveyancing; but the law has been greatly simplified by recent statutes (see CONVEYANCING). In Ireland the English law displaced and abolished the customs of the Celtic tribes; but the country never was thoroughly feudalised, and the peasant farmers have always been hostile to English notions of free trade in land (see LAND LAWS). In the United States (except Louisiana) and in those British colonies which have been formed in countries previously unsettled the English law of tenure forms the historical basis of the local law; but in a new country there are of course neither lords nor vassals, and the phrases of the feudal law only serve to remind us that land is and always must be held under some governing authority, and on such terms as legislators may impose upon the owners and cultivators.

For the early history of tenure, see Coulanges, *Origin of Property in Land* (trans. by Ashley); Elton, *Origins of English History;* Skene, *Celtic Scotland;* and Richey, *Irish Land Laws*. For curious tenures on quaint and merely nominal conditions, such as bearing a silver jug and basin as often as the king might visit the lands granted, see Thomas Blount, *Ancient and Jocular Tenures* (1679; new ed. 1815). For a comparison of modern forms of tenure, Cliffe Leslie, *Land Systems*, and the Cobden Club Essays may be mentioned. See also the articles BLANCH, CHARTER, COPYHOLD, FEU, FEUDALISM, FREEHOLD, &c.

Teocalli (Mexican, lit. 'house of a god'), the name given to the temples of the aborigines of Mexico, of which many still remain in a more or less perfect state. They were built in the form of four-sided pyramids, and consisted for the most part of two, three, or more stories or terraces, with the temple, properly so called, placed on a platform on the summit. In some cases they were natural hills, faced with layers of stone, adobe, plaster, &c. The largest and most celebrated is the pyramid of Cholula, measuring 1440



Teocalli at Palenque.

feet each way, and 177 in height; it is much defaced, and the temple on its summit has been removed. The teocallis in Yucatan are in far better preservation; they are not generally built in terraces, but rise at an angle of 45° to the level of the platform, with an unbroken series of steps from base to summit. The temples on their summit are sometimes ornamented with bas-reliefs and hieroglyphic tablets. The preceding illustration gives the elevation of a large teocalli of this kind at Palenque (q.v.). Not unlike the teocallis are the palaces of the Aztec kings or chiefs. See MEXICO.

Tepic, a town of Mexico, in the state of Jalisco, in a fertile upland valley, 30 miles E. by S. of San Blas. Its 25,000 inhabitants are largely employed in the numerous neighbouring mines.

Teplitz, a watering-place of Bohemia, is situated in a beautiful valley near the Erzgebirge, 20 miles NW. of Leitmeritz by rail. The baths are supplied from about a dozen hot alkalo-saline springs, are taken exceedingly hot, and have great virtue in restoring persons afflicted with gout, rheumatism, &c. One of the springs is used also for drinking. Pop. of Teplitz, with Schönau, 16,750. Some 7000 persons use the baths yearly.

Terai, or TARAI. See HIMALAYA.

Teramo (anc. *Interamna*), a town of Italy, the capital of a province (see Vol. VI. p. 240), on the Tordino, 84 miles S. of Ancona by a short branch-line. Its cathedral (1355) has been modernised. Pop. 8650.

Teraphim, a Hebrew word of uncertain derivation, denoting a certain kind of images, idols, or household gods, of a human figure, associated with divination, and commonly used in the popular worship. The *gods* which Rachel stole are called teraphim, and Saul's daughter Michel placed a teraph in David's bed to conceal his flight. This veneration for teraphim flourished side by side with the worship of Jehovah, though condemned by the prophets. The word in the Authorised Version is sometimes simply transcribed, sometimes variously rendered by *images, idols, idolatry.* See IDOLATRY.

Teratology, the study of malformations or abnormal growths, animal or vegetable. Those of the animal kingdom are treated at MONSTROSITY, DEFORMITIES, CLUB-FOOT, DWARF, HARELIP, &c. Those of the vegetable world form part of the subject of Vegetable Pathology, which deals with the diseases of plants (see that sub-heading under PLANTS, special articles such as ANBURY, &c.), and with excrescences caused by animals and parasites (see BEDEGUAR, GALL-FLY, GALLS, &c.; also BORING ANIMALS). Under this head come also abnormal forms like four-leaved clover, &c., as well as changes in the form of plants brought about by the skill of gardeners and agriculturists—such as the bulbous modification of the roots of turnips, the development of such a growth as cauliflower, the production of double-flowering plants, and the metamorphosis of organs. See BOTANY, CULTIVATED PLANTS, FLOWER, LEAF, HYBRID, MORPHOLOGY, and VARIATION; the articles on flowers that have been so developed—COCKSCOMB, DAHLIA, ROSE, &c.; the handbooks of morphological and physiological botany, but especially Masters, *Vegetable Teratology* (Ray Society, 1869), Penzig, *Pflanzen-teratologie* (1890), and Dareste, *Récherches sur la Production artificielle des Monstrosités* (2d ed. 1891).

Terburg, GERARD, painter, was born at Zwolle in 1608, studied first under his father, Gerard (1584–1662), and afterwards visited Italy and England, was at Münster during the congress of 1648, and later at Madrid. On his return he settled at Deventer, where he became burgomaster, and died 8th December 1681. The elegant life of his time, with its superfine manners and splendid costume, found in Terburg an admirable painter. The central figure in many of his

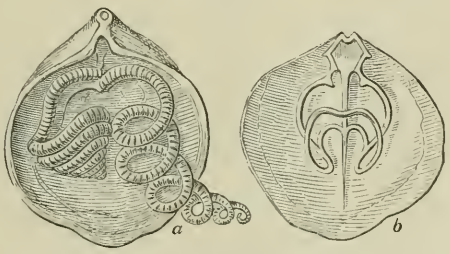
pictures is a fair-haired young lady in white satin; delicacy, grace, and humour, and marvellous mastery of technique in draperies inform all his work. His most famous picture is a small work on copper containing portraits of the sixty-nine plenipotentiaries who drew up the Treaty of Westphalia. See Michel, *Terburg et sa famille* (1888).

Terce. See Breviary; and for terce, the widow's portion, see Husband and Wife.

Terceira. See Azores.

Terebinth (Gr. *terebinthos*), another name for the Turpentine-tree, described at Pistacia, the genus to which it belongs, and for the turpentine obtained from it. Terebinthaceæ is a term that has sometimes been used either for a part or for the whole of the Anacardiaceæ, to which belong the turpentine-tree, pistachio-nut, mango, sumach, Japan lacquer (Rhus), &c.

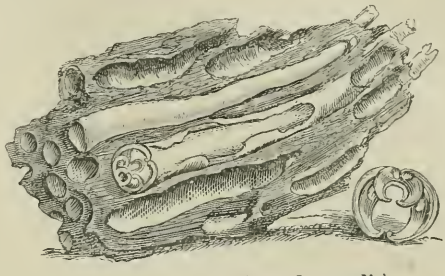
Terebratula, a genus of deep-sea Brachiopods, which, from the resemblance of the ventral valve of their shell to a Grecian lamp in form, are popularly termed Lamp-shells. The shell is symmetrical inequivalve, smooth to the naked eye, but when examined with a lens is seen to be minutely punctated. The ventral valve is the larger, the beak of which is produced and truncated at the apex, which is perforated. The animal is attached to the shell by a bundle of muscular fibres termed the pedunele,



Terebratula:
a, valve with the spiral arms; *b*, valve with arms removed.

which passes through the perforated apex of the ventral valve. There are only two British species. Fossil representatives appear at the conclusion of the Silurian period. Although termed deep-sea forms, Jeffreys considered that 'the nature of the sea-bottom, more than the depth of water, determines the limit of their habitability.'

Teredo, a genus of Lamellibranchiate molluscs of the family Teredinidæ (Gray), commonly known as shipworms, from the fact that they perforate and live in ships' timber, the woodwork of harbours, &c., causing considerable damage. They are of an elongate and worm-like form, measuring from a few inches to 3 feet in length. Two small valves form the bivalve shell situated at the anterior part of the body, in close proximity with the principal organs, which form a visceral mass. At the opposite end a pair of shelly paddles or 'pallets,' which vary in different species, close the burrow at the will of the animal. Their perforations are made usually in the direction of the grain of the timber, and the burrows are always distinct from one another. The burrow is lined with a calcareous substance secreted by the mollusc. The teredo does not feed upon the wood which it excavates. Whether the excavation is caused by the sucker-like application of the foot or the rasping action of the shell has not yet been satisfactorily demonstrated. The teredines reproduce themselves in large numbers, and grow with great rapidity. Extreme cold is fatal to them. As a protection from the ravages of these molluscs timber is often driven full of short broad-headed nails, which rust and form a coating which they do not penetrate. The teredo is often said to have been introduced into Europe from warmer climates,



Common Shipworm (*Teredo navalis*).

but facts do not bear out the statement. Tropical species will not live in European seas, and *vice versâ*. *T. norvegica*, which occurs in the North Atlantic, is found in the bordering countries in a fossil condition. The teredines were well known to the ancients, and are mentioned by Theophrastus, Pliny, Ovid, &c.

Terek, a stream of the Caucasus, rising near lofty Mount Kasbek, and flowing 350 miles, generally north-east, until, at Kisliar, it divides into several branches, which form a delta 70 miles broad, and finally falls into the Caspian Sea.

Terence. Publius Terentius Afer, Roman comic poet, was born at Carthage about 185 B.C., in the interval between the second and third Punic wars. He was presumably a Phœnician by race; and he became, by birth or purchase, the slave of the Roman senator P. Terentius Lucanus, who brought him to Rome, and, out of regard to his handsome person and unusual talents, educated him highly, and finally manumitted him. On his manumission he assumed, of course, his patron's *nomen*, Terentius. His first play was the *Andria*, acted in 166 B.C. Its success was immediate, and introduced its author to the most refined society of Rome, where his engaging address and accomplishments made him a great favourite. His chief patrons were Lælius and the younger Scipio, after living with whom in great intimacy for some years in Rome he went to Greece, doubtless with the view of becoming personally familiar with Greek life and manners; and there he seems to have died in 159 B.C., only about twenty-five years old. Six comedies are extant under the name of Terence, which are perhaps all he produced—viz. *Andria*, exhibited in 166 at the Megalensian games, an adaptation of Menander's *Andria* with additions from the same poet's *Perinthia;* the bright and lively *Eunuchus*, from Menander's *Eunouchos* and some parts of his *Kolax; Heauton Timoroumenos* ('the self-tormentor'), after Menander's play of the same title, without the use of another play, a comedy of intrigue, with a somewhat extravagant plot, and but little attempt at delineation of character; *Phormio*, so called from the parasite in the play, the original by Apollodoros of Karystos being entitled *Epidikazomenos*, a bright merry comedy, with an interesting plot and careful character-painting; *Hecyra*, the mother-in-law, his least successful piece, the plot poor and uninteresting, the characters peculiar; and *Adelphi*, from Menander's *Adelphoi*, with the addition of a scene from the beginning of Diphilos' *Synapothnēskontes*, an effective comedy, with simple and harmonious plot, and careful delineation of character—the two old men, the easy bachelor about town and the embarrassed country landlord, forming an inimitable contrast. Thus, as we have seen,

Terence has no claim to creative originality, his plays, Greek in origin and Greek in scene, being directly based on Menander, who, indeed, is best known to us through the works of his copyist. Cæsar, in a well-known epigram, addresses him 'O dimidiate Menander.' A foreigner in Rome and a total stranger to Greece when he wrote, he gave the still somewhat uncouth Romans a picture of the grace, elegance, and refinement of Greek manners; and he wrote in singularly pure and perfect Latin —ranked by Munro in the very highest level with Cicero, Cæsar, and Lucretius. His style, indeed, is pure almost to being immaculate, and, though inferior to Plautus in comic power, in mastery over passion, in vigour and variety, he is more than his match in consisteney of plot and character, in tenderness, in wit, in effective dialogue, and in metrical skill. He employs almost exclusively iambic and trochaic metres. He admitted and defended from the example of the older Roman poets the practice of *contaminatio*—constructing one Latin play by uniting scenes from several separate Greek ones. He was a true artist. In conjunction with Plautus, Terence, on the revival of letters, was studied as a model by the most accomplished play-writers. The *Eunuchus* is reflected in the *Bellamira* of Sir Charles Sedley and *Le Muet* of Brueys; the *Adelphi* in Molière's *École des Maris* and Baron's *L'École des Pères;* and the *Phormio* in Molière's *Les Fourberies de Scapin.* His plays have been translated into most of the European languages. Notable editions of his works are those of Bentley (1726), Davies, Parry, Fleckeisen (1857), Wagner (Lond. 1869), Umpfenbach (Berlin, 1870, the standard critical edition), and Dziatzko (Leip. 1884).

Teresa, or THERESA, ST, one of the most remarkable of the women saints of the modern Roman calendar, was born at Avila, in Old Castile, March 28, 1515, of the noble house of Cepeda. Even as a child she was remarkable for piety of a most enthusiastic kind; and, educated in a convent in her native city, she entered a convent of the Carmelite order there in 1534. In this convent she continued to reside for nearly thirty years, but it was not till about the year 1539 that her constitution became strong enough to permit her to follow, even in an imperfect way, the observances of conventual life. Her own account of her mental and spiritual condition is interesting from the first; but it was not till 1555 that a change of heart and of purpose came, which was as complete and decisive as her former condition had been purposeless or fluctuating. After a time her religious exercises reached a most extraordinary degree of asceticism. Her prayers were almost continual, and she was reported to be favoured with visions, ecstasies, and other supernatural visitations. The fame of her sanctity spread not only throughout Spain, but into almost every part of the church. By some the reality of the reported supernatural favours which were ascribed to her was called in question; and there were even some who threatened to invoke the rigorous investigation of the Holy Office; but the popular voice was freely accorded to her, and the authority of St Francis Borgia, St Peter of Alcantara, and other influential churchmen eventually disarmed the opposition. The most notable and permanent fruit of the enthusiastic spirituality of Teresa is the reform of the Carmelite order, of which she became the instrument. She commenced this work in concert with a few zealous members of her own sisterhood in the convent at Avila, where she had resided from the date of her profession; but after a time she obtained permission from the holy see to remove with her little community to a humble house in the same city, where she re-established in its full rigour the ancient Carmelite rule, as approved by Innocent IV. in 1247, with some additional observances introduced by herself. This new convent of St Joseph's was established in 1562, in which year she assumed the name of Teresa de Jesus; and in 1565 she obtained from the pope, Pius IV., a formal approval for the rule as modified by her. For two years Teresa lived in great privacy and quiet in her convent; but in 1567 the general of the Carmelite order, F. Rubeo, was so struck, during his visitation of the convents at Avila, with the condition of that over which Teresa presided that he urged upon her the duty of extending throughout the order the reforms thus successfully initiated. Teresa entered upon the work with great energy, and although she met with much opposition, nevertheless succeeded in carrying out her reforms. In 1579 the Carmelites of the stricter observance established by Teresa were released from the jurisdiction of the old superiors, and united into a distinct association, with a separate head and a distinct organisation, which was approved in 1580 by Pope Gregory XIII. Under this new constitution the association flourished and extended; and within her own lifetime no fewer than seventeen convents of women and sixteen of men accepted the reforms which she had originated. Teresa died at Alba, October 4, 1582, in her sixty-eighth year. She was canonised by Gregory XV. in 1622, her feast being fixed on the 15th October.

She left a number of works, which have at all times maintained a high reputation among a large section of her own church; their merits are also acknowledged by non-Catholic writers. They consist of ascetical and mystical treatises, instructions in the conventual life, meditations, besides a large number of letters which possess remarkable literary merit. The best-known treatises are her autobiography, *The Way of Perfection, The Book of the Foundations* (trans. by Dalton, 1853), and *The Interior Castle* (trans. by Dalton, 1852). Her works in the original Spanish fill two folio volumes (Salamanca, 1587), and they have been in whole or in part translated into almost every European language. Migne issued a French edition in 4 vols. (1840-46). Her life occupies nearly an entire volume of the *Acta Sanctorum;* and several biographies have been written in Spanish (Ribera's appeared in 1690), French, Italian, German—the best-known English ones being that by Canon Dalton (1851), one edited by Cardinal Manning (1865), one by Miss Trench (1875), one by Father Coleridge (3 vols. 1881-88), and Mrs Cunningham Graham's *Santa Teresa* (1894).

Terlizzi, a town of Italy, 22 miles W. of Bari. Pop. 20,442.

Term, a day fixed by law and usage for payment of rent, and for the commencement and termination of the contract between landlord and tenant; also the period between two terms. In England and Ireland the year is divided into four quarters or terms. These are Lady Day, March 25; Midsummer Day, June 24; Michaelmas Day, September 29; and Christmas Day, December 25. In Scotland the terms as between landlord and tenant are divided into legal and conventional terms. There are two terms recognised by common law—viz. Whitsunday, May 15, and Martinmas, November 11; while other two conventional terms subdivide these—viz. Candlemas, February 2, and Lammas, August 1. Removal terms and the terms by which domestic servants are engaged are the 28th May and 28th November. The Michaelmas term is the most important in England, whereas in Scotland it is Whitsunday. There is also a subdivision of the year into Law-terms; since the passing of the Judicature Acts the traditional terms are superseded by the times fixed for sittings of the courts by statute, but for some purposes we still distinguish Hilary, Easter, Trinity, and Michaelmas terms. At the English universities there are nominally four terms in the year, but

usage has established three working terms of about nine weeks each.

Termini, a seaport on the north coast of Sicily, 23 miles ESE. of Palermo by rail. Pop. 22,733. The industries are tunny and sardine fishing. The ancient *Thermæ Himerenses* here was founded by the Carthaginians in 408 B.C., after the destruction of the Greek city of Himera. Under the Roman rule it flourished through its baths. Of these some fragments still exist, as well as of a theatre, an aqueduct, &c.

Terminus, a Roman divinity, supposed to preside over public and private boundaries. Originally he appears to have been the same as Jupiter himself, but gradually he was recognised as a separate and distinct god.

Termites (*Termitidæ*), a family of insects in the order Corrodentia, or, according to some systems, Pseudo-Neuroptera. They are often called 'white ants,' but ants are Hymenopterous insects, and do not occur before Tertiary times, whereas the Termites seem to have lived from Carboniferous ages onwards. Yet, like the ants, the termites are

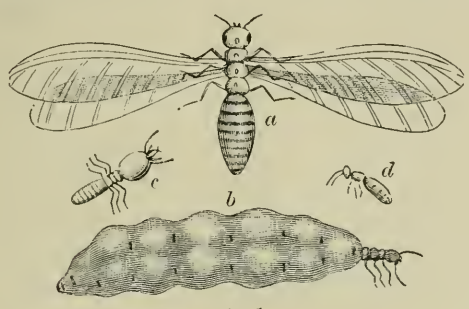


Fig. 1.
a, perfect male termite; *b*, female distended with eggs; *c*, soldier; *d*, worker.

social insects, living in colonies and building 'nests' or 'hills.' They are widely distributed in tropical countries, but they also occur in the temperate parts of North and South America, and a few have established themselves in Europe. As their food consists for the most part of wood, especially in a state of incipient decay, they help many trees to their fall, and they are destructive pests in human dwellings. As they form earthen tunnels up the stems and branches of the trees which they attack, and as the rains wash down these constructions, it seems just, as Henry Drummond points out, to recognise that termites, like earthworms, may help in making the fruitful soil.

The termite society consists for the most part of wingless, sexually immature individuals, children, potentially of both sexes, which do not grow up. Besides these workers there is a less numerous caste of large-headed, strong-jawed soldiers. 'They stand,' Drummond says, 'or promenade about as sentries, at the mouths of the tunnels. When danger threatens, in shape of true ants, the soldier termite advances to the light. With a few sweeps of its scythe-like jaws it clears the ground, and while the attacking party is carrying off its dead the builders, unconscious of the fray, quietly continue their work.' The workers collect food, form burrows and tunnels, build 'hills,' and care for the males, females, eggs, and larvæ. The males and females have wings, which the latter lose after impregnation. Then, indeed, the female or queen undergoes a remarkable change, becoming enormously distended with eggs and sometimes attaining a length of 2 to 5 inches or more—'a large cylindrical package, in shape like a sausage, and as white as a bolster.' As only the abdomen swells, the resulting disproportion between anterior and posterior parts is very striking. The queen is extremely prolific, having been known to lay 60 eggs in a minute, or about 80,000 eggs in a day. In the royal chamber a male is also kept. It is hardly necessary to say that the queen could not leave if she would. But to understand this imprisonment we must notice that in spring the young winged males and females leave the nest in a swarm, after which pairing takes place; the survivors becoming the imprisoned 'rulers' and parents of new colonies.

But Fritz Müller has shown that besides the winged males and females there are (in at least many cases) wingless males and females which never leave the termitary in which they are born, being kept as complementary or reserve reproductive members, useful should not a winged royal pair be forthcoming. Sometimes this casualty occurs, and then the wingless pairs become parents. The complementary kings die before winter; their mates live on, widowed, but still maternal, till at least another summer. Müller points out that, though the production and parentage of wingless males and females involves less mortality, the winged males and females probably cross with those from other nests, thus securing the advantages of cross-fertilisation. The workers are diligent in tending the king and queen, in removing the laid eggs, and in feeding the larvæ.

In general appearance and size a wingless termite is ant-like, but the winged forms are much larger and flatter, and their wings are quite different. The workers have large broad heads and strong jaws adapted for gnawing; the soldiers have still larger heads and longer jaws. Besides the jaws and the two pairs of maxillæ the head bears a pair of beaded antennæ, two eyes, and two ocelli, but the workers and soldiers are blind. The thorax has the usual three segments, and bears simple legs; the abdomen consists of nine segments.

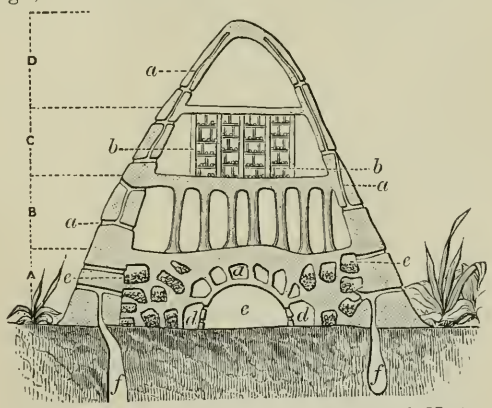

Fig. 2.—Diagrammatic section of a Termite's Nest (after Houssay):
In the walls there are winding passages, *a*; uppermost is a well-aired empty attic, D; the next story, C, is a nursery where the young termites are hatched on shelves, *b*; the next is a hall, B, supported by pillars; beneath this is a royal chamber, *c*, in which the king and queen are imprisoned; around this are the chambers of worker-termites, *d*, and some store-chambers, *e*; excavated in the ground are holes, *f*, out of which the material used in making the termitary was dug.

The most remarkable termitaries are those of *Termes bellicosus*, abundant on the west coast of Africa. They are sugar-loaf-like in shape, 10 to 20 feet in height, and, though built of cemented particles of earth, are strong enough to bear a man's weight. Internally, as the figure shows, there are

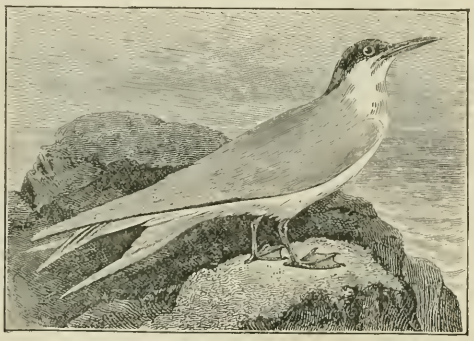
several stories and many chambers, some for the workers, one for the king and queen, others for the eggs and young, others for storing supplies of compacted minced wood. But the termites do not all build such gigantic nests; for some build their homes on the branches of trees and apparently out of masticated woody material.

In Africa *Termes bellicosus* and *T. arborum* are common species; in North America *T. flavipes* is very common. A few species—*T. lucifugus*, *T. flavicollis*, and *T. flavipes*—all probably introduced—occur in Europe. Besides Termes there are other genera, such as Eutermes, Calotermes, and Anoplotermes.

The termites seem to be of use in destroying decaying wood and in loosening the soil. They also afford food for ant-eaters and other insectivorous mammals and for birds. But to dwellers in warm countries they are pests, destroying the timbers of houses and all sorts of wooden furniture. Effecting entrance from underground, they hollow out the interior, leaving only a deceptive shell, which at length collapses. Even in Europe *T. lucifugus* has proved very destructive in some parts of France, notably in the navy-yard of Rochefort. Yet to the naturalist their social life, their reproductive relations, and their architectural instincts are most interesting marvels demanding further research.

See H. A. Hagen, *Monographie der Termitiden* in *Linnæa Entomologica* (vols. x.–xiv. 1855–59); Ch. Lespès, *Recherches sur l'Organisation et les Mœurs du Termite lucifuge* (Ann. Sci. Nat. 4th series, vol. v. 1856); Fr. Müller, *Beitrage zur Kenntniss der Termiten* in *Jenaische Zeitschr. f. Naturwiss.* (vols. vii.–ix. 1873–75); Smeathman, *Some Account of the Termites which are found in Africa*, &c. (Trans. Roy. Soc. 1781); Grassi, *Memoria sulla Società dei Termiti* (Accad. Lincei, Roma, 1892).

Tern, the name applied to several genera of birds of the Gull family (Laridæ), by some made into a sub-family (Sterninæ); they have the bill as long as or longer than the head, nearly straight, compressed, slender, tapering; the wings long and pointed; the tail usually long and more or less forked, sometimes graduated; the legs and feet short and small. In plumage the terns resemble the gulls, but are usually smaller. From this, and from their forked tail, they are often called Sea-swallows, though their flight is more like that of a gull. They are constantly on the wing, swooping on small fishes and other small animals in the water, or catching insects over the land. The species are numerous, and found all over the world,



Common Tern (*Sterna fluviatilis*).

frequenting fresh as well as salt water. Those which occur in the north migrate south in winter. Some species have a very wide range. Thus, the Common Tern (*Sterna fluviatilis*), abundant on the more southern coasts of Britain, is also found on the coasts of Europe, western Asia, western Africa as far as Accra, and eastern North America. In Cashmere, Tibet, and south Siberia it is replaced by a nearly allied species, *S. tibetana*, which visits Ceylon and South Africa in winter. Terns make little or no nest, laying their spotted eggs on sand or shingle, from which they are often with difficulty distinguished. Some, however, breed in marshes, and some build on trees and bushes, as the Noddy (*Anous stolidus*). This bird derives its name from the ease with which it is caught when it alights on ships to rest; it has a graduated tail, and is sooty-brown, with a gray cap. It is found in all tropical waters, and has even occurred on the Irish coast. The Sooty Tern (*S. fuliginosa*) breeds in vast numbers on Ascension Island, where it is known as the 'Wideawake.'

Ternate. See Moluccas.

Terni, a cathedral city of Central Italy, between the two arms of the Nera, 70 miles NNE. of Rome by rail. Pop. 9415. About two miles off is the famous cataract of Velino, 500 feet high, celebrated by Byron in his *Childe Harold*. Terni is the ancient *Interamna Umbrica*, perhaps the birthplace of Tacitus.

Ternstrœmiaceæ, a natural order of polypetalous plants, consisting of trees and shrubs, natives of warm and temperate countries. About 150 species are known. They are most abundant in South America; a few are found in North America; some in India, China, and the Indian Archipelago. The leaves are alternate, leathery, in many species evergreen, generally undivided, sometimes dotted. This order is very important as containing the Tea-shrubs. It is also interesting because of the great beauty both of the foliage and flowers of many of the species, of which the genus Camellia affords the best-known examples. See Tea, Camellia, and Gordonia. The genus Ternstrœmia was named in 1781 from the Swedish naturalist Ternström.

Terpsichoré (Gr., 'delighting in the dance'), one of the nine Muses (q.v.), presided over choral song and dancing.

Terraces, in Geology, comparatively level strips of land near the sea, lakes, or rivers, with a sharp descent at the edge towards the water, showing an ancient water-level. See Beaches (Raised), Glenroy, River, Lake, Valley.

Terracina, a coast town of Central Italy, 60 miles SE. of Rome. It has a cathedral on the site of a heathen temple, and on the summit of a precipice overlooking the town the ruins of a palace of king Theodoric. Pop. 6294. The Roman *Tarracina* was originally a Volscian town (*Anxur*), and down to the fall of the empire was an important station on the Appian Way.

Terra-cotta, an Italian term for pottery or earthenware ('baked clay'). The name is not applied in England to ordinary pottery vessels with thin walls, but is confined to objects of the nature of bricks, and usually of comparatively large size and unglazed. Statues, statuettes, bas-reliefs, and architectural members such as columns, cornices, friezes, consoles, and the like made of burnt clay are said to be executed in terra-cotta whether they are ancient or modern. But the term is not confined to articles of a decorative character. The colour of terra-cotta is either buff yellow, or red, the former being the more common. Many masterpieces of ancient Greek and Roman sculpture are executed in this material, and a considerable number of works in burnt clay, by Italian artists who lived in the middle age and early Renaissance periods, are also exquisite productions. Illustrations of a number of these ancient works of art in terra-cotta will be found in the published

catalogues of the British Museum and the South Kensington Museum. Architectural ornaments of a very effective kind were also executed in this material in ancient times.

Distinguished modern sculptors sometimes produce works in terra-cotta, and for the last thirty or forty years it has been increasingly employed, either partly or wholly, for the fronts and other portions of important buildings (see DOULTON, TINWORTH). The new Natural History Museum at South Kensington and a few other buildings in its neighbourhood, as well as elsewhere in London, are examples. Terra-cotta is peculiarly well suited for architectural work in towns like the metropolis where stone too readily decays, or in cities to which stone has to be brought from a long distance. Berlin is thus remotely situated, and in that city many large and highly ornate modern buildings are executed in this material. See C. T. Davis, *Manufacture of Brick, Terra Cotta, &c.* (new ed. 1889).

Terra del Fuego. See TIERRA DEL FUEGO.

Terra di Lavoro, the old name for the province of Caserta (q.v.).

Terra-firma, a term frequently employed to denote continental land as distinguished from islands. But it was at one time more specially applied to all the mainland of Italy which acknowledged the supremacy of Venice, and to the northern part of South America. Colloquially, the phrase *terra-firma* is applied (but erroneously) to land as distinguished from water.

Terra Japonica. See CATECHU.

Terranova, a seaport on the south coast of Sicily, 60 miles W. of Syracuse. Pop. 16,440.

Terrapin, the popular name of many species of fresh-water and tidal-water tortoises of the family Emydidæ, natives of tropical and the warmer temperate countries. About twenty fresh-water species are found in the United States. But the terrapin *par excellence* is the *Malacoclemmys palustris*, the diamond-back salt-water terrapin, highly prized as a delicacy for the table. It is caught in salt marshes along the coast from New England to Texas, the finest being, however, those of the Massachusetts and the northern coasts. At their best terrapin vary in price from $10 to $55 a dozen, according to size and quality. Another species is *M. geographicus*, with peculiar map-like markings; and there are several species of Pseudemys. 'Brer Tarrypin' is an intelligent and genial interlocutor in many of the beast stories of *Uncle Remus*. See TORTOISE.

Terra Rossa, name given to a ferruginous red earth which is extensively developed in the limestone districts of south-eastern Europe, especially in Istria and Dalmatia. See RED EARTH.

Terre Haute (*Terre* pron. *Ter-re*), capital of Vigo county, Indiana, on the river Wabash (crossed here by three bridges), 72 miles by rail WSW. of Indianapolis and 178 S. of Chicago. It is regularly built on a plateau some 60 feet above the river, and, being within a dozen miles of the great block-coal mines of Clay county, contains numerous foundries, rolling and other mills, and factories. Its public institutions include the state normal school, a college, a polytechnic and other institutes, an orphans' home, &c. Pop. (1870) 16,103; (1880) 26,042; (1890) 30,217.

Terrestrial Magnetism, &c. See MAGNETISM, p. 801, and TEMPERATURE.

Terrier, a name originally applied to any breed of dog used to burrow underground, but now applied to any small dog. Terriers may be divided into three classes: those able to follow their game into its earth, those kept for hunting above-ground, and those kept merely as companions. Among terriers proper the Fox-terrier (q.v.) holds the position of greatest popularity. The Scotch terrier, though long familiar in Scotland, only became generally known about 1870, but is spreading so rapidly that it threatens even the popularity of the fox-terrier. The Scotch terrier is identical with the breed often erroneously alluded to as the

Scotch Terrier, 'Rascal.'

old or working Skye terrier. He is a small, compact dog, short in the leg; coat short, hard, and dense; ears erect; and with a keen, bright expression. In character he is generally alert and active, and makes a splendid companion. The third variety used for going to ground is the Dandie Dinmont, called after the character in Scott's novel of *Guy Mannering*, a character founded on Mr Davison, a well-known Border farmer, who was one of the founders of the breed. The Dandie is a low and powerful dog, very courageous, a quality probably gained by an admixture of bulldog blood, but headstrong and difficult to keep under control. Dandies are divided into 'peppers' and 'mustards'—i.e. those coloured slate-blue and those of a light yellow. The coat is rather longer than the Scotch terrier, but not so hard.

Among terriers kept for hunting above-ground the most popular is the Irish terrier, a dog larger and considerably leggier than the fox-terrier, but built on the same lines. The coat is like the Scotch terrier's, but a light red in colour. The ears used always to be cut to a fine point, standing erect, but are now allowed to fall over in their natural shape. The Bedlington (q.v.) is popular in the north of England; the Bull-terrier (see BULLDOG) also makes a good sporting dog, but is kept mainly as a companion. The Airedale is growing in popularity, but its large size (some specimens weigh 60 lb.) unfits it for any proper terrier work. It somewhat resembles an overgrown blue Bedlington, but lacks the same courage. Among terriers kept as companions the Skye (q.v.) is probably the most common. The Black-and-tan terrier, though a breed of great antiquity, is fast being supplanted by the white English terrier. Both breeds are identical in shape, and resemble a light and elegant bull-terrier. The Toy terrier is a cross from the black-and-tan, as is the Yorkshire terrier. Both varieties are fit only for house-dogs, and are not true terriers.

Terror, REIGN OF. See DANTON, ROBESPIERRE.

Terry, ELLEN (Mrs Charles Kelly), the leading English actress of the day, was born at

Coventry, on 27th February 1848. She made her first appearance on the stage when only eight years old, playing Mamilius in *The Winter's Tale* at the Princess's Theatre, under the management of Charles Kean. In 1858 she acted the part of Arthur in *King John*, and in 1863 made her debut as a regular performer, playing Gertrude in *The Little Treasure* at the Haymarket. From 1864 to 1874 she practically retired from the stage, her only notable appearances being at the Queen's Theatre for a few months in 1867. In 1875 she made a great success in Portia at the old Prince of Wales's Theatre, where she remained for some time under the Bancrofts, playing in *Money*, *The Lady of Lyons*, *Masks and Faces*, and *Ours*. In 1876 she joined the Court Theatre, where her most notable character was Olivia, in Mr Wills's play of that name. On 30th December 1878 she first appeared at the Lyceum in conjunction with Mr Irving (q.v.), with whose brilliant successes her name is inseparably connected. The distinctive feature of Miss Terry's acting is womanliness, and the grace of all her movements and attitudes, the expressiveness of her face, and the simple truth and directness of her speech give all her impersonations a singular charm. Among her best characters are Beatrice, Portia, Ophelia, Olivia, Margaret, Henrietta Maria, and Nance Oldfield.

Terschelling, one of the chain of islands to the north of Holland. It consists of fertile arable and meadow lands, is protected on the south by large dykes, and in other parts by dunes, which are carefully preserved. Area, about 45 sq. m.

Tertian Fever. See AGUE.

Tertiaries, a name given by church writers to a class in the Roman Catholic Church, who, without entering into the seclusion of a monastery, aspire to practise in ordinary life all the substantial obligations of the scheme of virtue laid down in the Gospel. It was under St Francis and the mendicant orders generally that the institute of Tertiaries reached its full development (see FRANCISCANS). Similar lay associations were organised in connection with the Dominican, Carmelite, and Augustinian, as well as with certain of the more modern orders; and a brotherhood of the same character had already been formed by the Templars. The institute of Tertiaries, properly so called, is quite distinct from that of the lay 'confraternities' which exist in connection with the several orders, and the objects of which are very similar.

Tertiary, or CAINOZOIC, the term applied in the science of Geology (q.v.) to all the strata of the earth's crust above the Cretaceous Rocks, with the exception of those superficial beds which have recently been raised to a distinct group, under the title of the Quaternary or Post-tertiary. The Tertiary systems include Eocene, Oligocene, Miocene, and Pliocene.

Tertullianus, QUINTUS SEPTIMIUS FLORENS, a great theologian of the Western Church, was born of heathen parents at Carthage about 160. His father was a Roman centurion under the proconsul of Africa. The details of his life are little known, but the strongly marked character of the man comes out in every page of his numerous writings. He had a liberal education, and shows extensive acquaintance with poetry, history, and law, and considerable knowledge of philosophy and science, though he calls the philosophers 'the patriarchs of heretics' and the learning of secular literature 'folly with God.' He speaks of the delight he once had in the indecent profanities of the public plays, and confesses that he had fallen into the greatest sins. He nowhere says much about his personal religion, but calls himself 'a sinner of all brands, and fit only for penitence, and asks his readers to remember in their prayers Tertullian the sinner.' He had sufficient command of Greek to write in that language his earliest treatises, all of which are lost. Jerome mentions that he was a presbyter of the Catholic Church, whether at Rome or Carthage is unknown. Tertullian himself speaks of his having lived at Rome. Eusebius says 'he was accurately acquainted with the Roman laws, and one of the most distinguished men in Rome.' It is possible that before his conversion he had practised there as an advocate or rhetorician. He did not become a Christian till about 190, and he has not recorded the history of his conversion. That he was married is shown by his two books *Ad Uxorem*, in which he argues against second marriages. Some time between 199 and 203 his opposition to the spirit of worldliness in the church culminated in his becoming a leader of the Montanist sect. According to Jerome, this was owing to 'the envy and insults of the clergy of the Roman Church,' but the chief causes were doubtless the uncompromising character of his natural disposition, and his repugnance to the laxity of the Roman clergy in their reception of the *Lapsi*, and very probably the favour shown to the Patripassian heresy by the Roman bishops Zephyrinus and Callistus. He died between 220 and 240, 'in decrepit old age' (Jerome). Augustine says that he at last withdrew from the Montanists, and 'propagated conventicles of his own,' which is rendered less likely by the fact that the Montanist sect survived in Africa till the 5th century, under the name of 'Tertullianists.'

Tertullian was a man 'of an eager and vehement disposition' (Jerome), who threw all his great gifts of learning, imagination, eloquence, and wit into the religious controversies of his time for thirty years (190–220). Along with the Roman love for substantiality and strength, he had the 'bitter, stern, and harsh temper' which Plutarch ascribes to the Carthaginians. He wanted the sweet reasonableness and calmness, the feeling for harmonious form, and the instinct for speculative thought that distinguish the greatest Greek fathers of the church. He had the heart of a Christian with the adroit intellect of an advocate. His aim is always to make his adversaries appear ridiculous and contemptible. He pours unsparingly upon them a fiery stream of strong argument and satire, mixed with the sophisms, insinuations, and hyperboles of a special pleader. His style is most vivid, vigorous, and concise, abounding in harsh and obscure expressions, abrupt turns, and impetuous transitions, with here and there bursts of glowing eloquence, reminding the reader at one time of Carlyle, at another of Lamennais. What appear to be African provincialisms Niebuhr contends are only words and expressions taken from the ancient Latin writers. He was the first to give such words as *persona*, *liberum arbitrium*, *trinitas*, *satisfactio*, *sacramentum*, *substantia*, &c. the place they hold in Christian theology. Many sentences of Tertullian's, as, for example, 'the blood of the martyrs is the seed of the church;' 'Christ is truth, not custom;' 'It is absolutely credible because absurd—it is certain because impossible;' 'the human race has always deserved ill of God;' 'the unity of heretics is schism;' 'it is contrary to religion to compel religion;' 'how wise an arguer does ignorance seem to herself to be,' have become proverbial. 'Who can sufficiently extol the eloquence of Tertullian!' exclaims Vincentius of Lerinum; 'almost every word conveys a thought, every sentence is a victory. He is among the Latins what Origen is among the Greeks—the greatest of all.' Like Origen, Tertullian was a man of great genius, sincerity, and zeal, a vigorous ascetic, and an indefatigable worker, and, though wielding great influence over his contem-

poraries, was never more than a presbyter. Like him, too, this champion of the Christian faith against all opponents, Jews, heathens, and heretics, was himself a heretic to the majority of the Christians of his time. Both show the same contempt of the world and enthusiasm for martyrdom. But in the tendency of their views the contrast between them is as striking as in their natural temper and their literary style. Tertullian is an intense realist, with leanings towards materialism, Origen a pure idealist. Origen, like Justin, holds that Greek philosophy was 'a preparation for the Gospel,' 'a fragment of eternal truth from the theology of the ever-living Word.' Tertullian thinks that 'philosophers are blockheads when they knock at the gates of truth,' and that 'they have contributed nothing whatever that a Christian can accept.' 'The eloquence of the one,' says Pressensé, 'is broad and transparent like his genius: it is a noble, full, majestic river: that of the other is a turbid mountain-torrent. Origen speaks to philosophers as a Christian philosopher: Tertullian is a tribune of the people passionately haranguing the crowd in the forum or at the cross-roads; he is the ancient orator, with his vehement gestures, his vivid images, his grandiose pathos.'

His writings have been called 'Tracts for the Times.' Most of them are short. They are a rich mine of information as to the relations between Christians and heathens in his time. Though perhaps not the first of the Latin Christian writers, Tertullian was the creator of ecclesiastical Latinity, and impressed upon the language a new character, as he bent it to the service of Christian ideas. His works are divided into three classes: (1) Controversial writings against heathens and Jews. His *Apologeticus* (ed. by Woodham, 1843; by Bindley, 1891), addressed to the Roman authorities, is an attempt to establish the Christians' right to toleration. A popular edition of this work is presented in his two books *Ad Nationes*, possibly, as Uhlhorn and Hauck believe, of earlier date. *Ad Scapulam* is a bold rebuke of the persecuting Roman proconsul Scapula. In his *De Testimonio Animæ* he acutely develops the thought that Christianity responds to the religious necessities and postulates of human nature. The treatise *Adversus Judæos* is to prove that prophecy is fulfilled in Christ.

(2) Against heretics. Against these Tertullian takes his stand, as Irenæus did before him, on the old apostolical tradition as the fixed foundation of belief. He formulates this position juristically in his *De Præscriptione Hæreticorum*. Against the Gnostic attempts to volatilise Christianity in Gnostic spiritualism he maintained its reality as a practical form of life in his *De Baptismo*, *Adversus Hermogenem*, *Adversus Valentinianos*, *De Anima* (in which he contends that even the soul is material), *De Carne Christi* (against Docetism), *De Resurrectione Carnis*, and the five books *Adversus Marcionem*. Against the Patripassian heresy he wrote the book *Adversus Praxean*.

(3) Practical and ascetic treatises. It is especially in these writings relating to Christian life and discipline that we can trace Tertullian's increasing hostility to the church and adoption of the Montanist views, which had great influence among African Christians. He hailed the testimony of 'free prophecy' as God's witness against the laxity which the Catholic Church had shown in dealing with the sensual weaknesses of the great multitude within her pale. Hence the division of these treatises into *Pre-Montanist* and *Montanist*. To the former class belong *De Baptismo*, *De Pœnitentia*, *Ad Martyres*, *De Spectaculis*, *De Idolatria*, *De Cultu Feminarum*, *De Oratione*, *De Patientia*, and *Ad Uxorem;* to the latter, *De Corona*, *De Fuga in Persecutione*, *Scorpiace*, *De Exhortatione Castitatis*, *De Monogamia*, *De Pudicitia*, *De Jejunio*, *Adversus Psychicos*, and *De Pallio;* while *De Virginibus Velandis* marks the transition stage.

Tertullian had a greater influence on the Latin Church than any theologian between Paul and Augustine. His Montanism indeed prevented it from being exercised directly, but Cyprian, who called Tertullian 'his master,' was the interpreter who gave currency to his views. The following is a summary of Harnack's estimate of Tertullian (3d vol. of his *Dogmengeschichte*), whom he calls 'the founder of Western Christianity.' Tertullian's Christianity was moulded by the enthusiastic and strict faith of the early Christians on the one hand, and by the anti-Gnostic *regula fidei* on the other. A trained jurist, he sought to express all religion in legal formulas, and conceived the relation between God and man as one of civil law. 'God appears always as the powerful partner, who watches jealously over his rights.' Further, his theology shows a syllogistic-dialectic stamp; it does not philosophise, it reasons, using now the argument *ex auctoritate*, now the argument *e ratione*. He shows striking power of psychological observation. Finally, his writings have a strong practical evangelic tendency; with their vivid appeal to the reader's will, and their simple concrete expression of the Gospel, they appealed not to theologians only, but to all. In these characteristics, and their union, Tertullian became the type of the Christianity of the Western Church.

The best complete edition of Tertullian's works is still that of Oehler (3 vols. Leip. 1853-55). A complete critical edition is being published in the Vienna *Corpus Script. ecclesiast. Lat.* (part i. by Reifferscheid and Wissowa, 1890). The most important studies are those of Kaye (*Eccles. Hist.*, 3d ed. Lond. 1845), Neander (*Antignosticus*, 2d ed. Berlin, 1847; Eng. trans. by J. E. Ryland, 2 vols. 1851), Pressensé (in his *Histoire des Trois Premiers Siècles de l'Église Chrétienne*, 1858–77; Eng. trans. 4 vols. 1879), Böhringer (*Biographien*, vol. iii. 2d ed. Leip. 1875), Möhler (in his *Patrologie*, vol. i. Regensburg, 1840), Grotemeyer (Kempen, 1863–65), Freppel (Paris, 1864), Hauck (with a selection of characteristic extracts, Erlangen, 1877), J. M. Fuller (in the *Dictionary of Christian Biography*, 1887), Farrar (*Lives of the Fathers*, vol. i. 1889), and Ernst Noeldechen (Gotha, 1890). See also Harnack, *Dogmengeschichte* (2d ed. 1888–90), N. Bonwetsch, *Die Schriften Tertullians* (1878); Koffmane, *Geschichte des Kirchenlateins* (vol. i. Berlin, 1879); Van der Vliet, *Studia ecclesiastica. L. Tertulliani* (Leyd. 1891). Translations of nearly all Tertullian's works are included in Clark's *Ante-Nicene Christian Library*.

Tesla, NIKOLA, born the son of a Greek priest at Smiljan in Servia, in 1857, studied at Gratz and Paris, and in 1885 joined Edison at Menlo Park, but left him in order to work out in New York his own inventions—telegraphy through the earth without wires, the securing of an effective electric light by means of Vacuum Tubes (q.v.), the controlling of a torpedo boat from the shore by electricity, &c. In 1894 a book on *The Inventions of Tesla* was published at New York.

Testacella, a genus of molluscs belonging to the *Pulmonifera*, and represented in Britain by three species. The shell, which consists of but half a whorl, is situated at the hinder end of the body. They are of subterranean habits and carnivorous, feeding chiefly upon earthworms. They usually come out in search of their prey during the night. In winter they form a cocoon-like body of cemented particles of earth, &c., which covers the upper part of the body.

Test Acts, acts meant to secure that none but rightly affected persons and members of the established religion shall hold office, include all such

acts as enforce oaths of Abjuration, Allegiance, Supremacy, or, amongst the clergy, Uniformity; as well as the Corporation Act of 1661, requiring members of corporations to receive the sacrament after the manner of the Church of England. But the term is specially used of two English statutes imposing certain oaths on the holders of public offices, and directed against Catholics. The act of 1673 directs that all magistrates shall take the oaths of allegiance and supremacy, as well as an oath renouncing the doctrine that it is lawful to take arms against the king, and provides that they must receive the communion according to the rites of the Church of England within a year before their election. A Scottish act was passed in 1681. Another act of 1685 imposed the like conditions on the holders of all public offices, civil and military, and obliged them in addition to abjure all belief in the doctrine of transubstantiation. These acts, which were practically evaded to a large extent by means of an act of indemnity passed every year, and were at various times partially repealed, were not finally repealed till 1829. In Scottish church history of the 17th century 'taking the test' meant taking the oaths, abjuring the Covenant, and recognising the reigning king, oaths enforced on all and sundry, especially on Covenanters, during the 'killing times.' The universities had their own special tests, now abolished save in the case of offices with clerical functions. See OATH.

Testament. See BIBLE, and WILL.

Testing, in Chemistry. See ANALYSIS.

Testing Clause, in a Scottish deed, is the last clause, which narrates when and where the parties signed the deed, before what witnesses, the number of pages of which the deed consists, and who was the person who penned the deed. Moreover, if there have been any interlineations or erasures of important words during the engrossing, these should be mentioned in this clause. The clause is an essential part of a Scottish deed, and no deed written by another than the party is valid unless the testing clause is regular. See DEED.

Test-papers are made by dipping unsized paper into an alcoholic solution of a vegetable colouring matter which changes colour when exposed to the action of an acid or alkaline solution. The paper, after being gently dried, is cut into slips of a suitable size. Hence, by dipping the appropriate test papers into any solution, we can ascertain whether it is acid, alkaline, or neutral. Litmus and turmeric are most commonly used as the colouring matters; litmus for the detection of acids, and turmeric for that of alkalies. Test-papers are also employed for detecting sulphuretted hydrogen, &c., and for such a purpose the paper must be dipped in the solution of an appropriate substance. Thus acetate of lead paper becomes black in presence of sulphuretted hydrogen, while starch paper becomes blue when touched with iodine.

Testudo. See TORTOISE.

Tetanus (derived from the Gr. *teinein*, 'to stretch'), or LOCK-JAW, is one of the most formidable diseases of the nervous system, and is characterised by an involuntary, persistent, intense, and painful contraction or cramp (see SPASM) of more or less extensive groups of the voluntary muscles, nearly the whole of the body being sometimes affected. The muscles of the neck, jaws, and throat are almost always the first to give evidence of the presence of the disease. The neck feels stiff, the jaws are opened with difficulty, and often become tightly clenched, and the face has a peculiar fixed smile (*risus sardonicus*). The disease spreads to the muscles of the trunk and the larger muscles of the limbs; the former is almost always strongly arched backwards (*opisthotonos*); the hands and feet are usually but slightly affected, if at all. These muscular contractions are very painful; a particularly acute pain is frequently present in the lower part of the chest, probably due to spasm of the diaphragm. Some of the muscles affected, as, for example, those of the abdomen, are so rigid as when struck by the fingers to resemble a board, and a perfect remission of the spasm scarcely ever occurs, except sometimes during sleep. Exacerbations of the spasms, on the other hand, commonly come on every ten minutes or quarter of an hour, usually beginning by an increase of the pain at the sternum, and lasting for two or three minutes: and as the disease advances these paroxysms become more frequent. They may occur spontaneously, or may be induced by the slightest disturbance—a touch, a draught, a noise, or the slightest attempt at movement.

During the exacerbations the face of the patient often presents a positively frightful appearance. The tongue is apt to get bitten during the contractions, which are occasionally so violent as to break the teeth, rupture powerful muscles, and, at least in one case, to fracture the thigh-bone. Death usually results from a mixture of causes, but mainly from want of breath, due to the fixed condition of the respiratory muscles, associated with asthenia (loss of power), and flagging of the heart's action. Fever may be absent during the whole course of the disease, and if present is not generally severe. Sometimes, however, the temperature becomes extremely high (110° or 112° F.) just before death.

The disease occasionally occurs after exposure to cold, still more rarely without any discoverable cause whatever. Such cases are called *idiopathic*. In the vast majority it follows some injury involving a breach of surface (*traumatic tetanus*). It more frequently attends upon severe injuries, but it may result from a slight prick or scratch, and the severity of the disease bears no proportion to the extent of the wound. Nor does the seat of the wound seem to have any importance; the popular idea that injuries of the thumb are specially apt to lead to it is not supported by statistics. The period of its commencement varies from a few hours to many days after the injury; death occurs in most fatal cases within a week of the first onset. It is met with at all ages, but is much more common in males than females. Idiopathic cases, and those commencing more than three weeks after an injury, are as a rule less severe. But 'taking all forms together in a fair average number of cases, the proportion seems to be 7½ deaths to 1 recovery' (Holmes's *System of Surgery*).

Various forms of local irritation may set up a localised trismus or lock-jaw, but its distinction from true tetanus seldom presents much difficulty. Tetanus at its commencement is sometimes mistaken for rheumatism, and has some resemblance to Hydrophobia (q.v.). It may be closely imitated by hysteria, but particularly by poisoning with nux vomica, or its alkaloids strychnia and brucia. In these cases the more sudden development of the symptoms, and the less persistent rigidity between the spasmodic paroxysms, are the most prominent distinguishing features.

With regard to *treatment*, perfect quiet and the avoidance of all possible causes of irritation and excitement are the first things to be insisted upon. The patient's strength must be maintained by liquid nourishment, given by injection, or even administered under chloroform if necessary. Many drugs have been used; chloral in repeated doses perhaps with most apparent benefit, but the great majority of cases have hitherto defied all treatment.

The *cause* of the disease has long been suspected to be a micro-organism; among other reasons, because tetanus, as a result of surgical operations, has become much less frequent since the introduction of Antiseptic (q.v.) methods. Nicolaier (in 1884) first described the bacillus now known to be the cause of tetanus; but Kitasato, working in Berlin, was the first to obtain pure cultures, and to give a complete demonstration that tetanus must be added to the infective diseases (1889). Methods have since been discovered whereby animals can be rendered 'immune' or incapable of inoculation with tetanus. Tizzoni and Cattani, experimenting with such animals, found a substance in their blood, called by them the *antitoxine* of tetanus, which neutralises the virus of tetanus even outside of the body, and when injected into other animals produces immunity against, and even cure of the disease (1891). This substance was used in the treatment of the disease in the human subject. Roux, finding that the failures were due to the anti-toxin never reaching the brain, tried (1898) inoculation of the anti-tetanus serum direct into the brain of the affected person or animal.

Tetany is a rare and little understood disease of the nervous system, occurring both in children and adults, characterised by recurring attacks of tonic spasm of various muscles, particularly those of the fingers and toes. It is associated with defective hygienic conditions, imperfect ventilation, poor diet, and in children with Rickets (q.v.). Complete recovery generally ensues; fatal cases are very rare.

It is not yet definitely settled to which of these two very different diseases *tetanus* or *trismus neonatorum* (of newborn children) should be referred. It has been supposed on the one hand to be traumatic tetanus, due to the injury to the umbilical cord at birth, and resembles it in its great fatality, and in the extension of the spasms over the larger muscles (of trunk, &c.); the opposite view, that it is an extremely aggravated form of tetany, is supported by the facts that the muscles of the fingers and toes are specially affected, and that improved ventilation alone has been known to produce a great diminution of the disease in lying-in hospitals.

Tetanus, or lock-jaw, both traumatic and idiopathic, occurs in most of the domesticated animals, but most frequently in horses and sheep. It is now proved to be due to the action of a microbe, the *Bacillus Tetani*, which gives rise to the formation of a ptomaine termed *Tetanine*, by the action of which the tetanic symptoms are induced. This bacillus is also found in garden-mould, and most probably tetanus is induced by the entrance of the microbe into a wound or exposed structure. Tetanus has been transmitted from diseased to healthy animals by inoculation. The symptoms usually come on gradually, involve most of the muscular structures, which become hard and rigid; the nose is protruded, the limbs move stiffly, the tail is upraised, the bowels are constipated. The patient must be kept perfectly quiet, and in an airy but fairly warm place, and plentifully supplied with cold water, and with soft, sloppy, but nutritive food, which he will usually greedily suck in through his firmly-closed teeth. A full dose of purgative medicine must at once be given; extract of belladonna repeated twice or thrice daily is occasionally serviceable; any discoverable wound or injury should be fomented or poulticed; bleeding, sedatives, and all causes of irritation must be avoided. In adult animals most cases are fatal; but amongst young animals many recoveries occur.

Tetbury, an old market-town of Gloucestershire, 5 miles NW. of Malmesbury. Pop. 2173.

Tête-du-Pont. See Bridge-head.

Tetrao. See Grouse.

Tetrarch (Gr. *tetrarchēs*, Lat. *tetrarcha*, 'governor of the fourth part,' i.e. of a country), a title originally designating what is signified by its etymology, the governor of one of four divisions of a kingdom or country; but in the usage of the later Roman empire given undistinguishingly to all minor rulers, especially in the East, possessing sovereign rights within their territory, but dependent on the emperor, and in many cases removable at his pleasure. This was especially the case in Syria, where the princes of the family of Herod are called indiscriminately by this title (Luke, iii. 1) and by that of king (Matt. xiv. 9).

Tetter, the popular name for skin diseases of the kind described under Psoriasis and Herpes.

Tetuan (Arab. *Tetawin*), a port of Morocco, about 4 miles from the sea, 22 miles S. of Ceuta. It is surrounded by walls, flanked with towers, and is defended by a castle. Its harbour does not admit large vessels; but a brisk trade is carried on, mainly by the Jews, in fruit, wool, silk, girdles, leather, cotton, &c., and it exports provisions largely to Ceuta. Tetuan was taken by the Spaniards under O'Donnell (q.v.), February 1860, but was evacuated next year. Pop. 22,000 (one-third Jews).

Tetzel, John, the famous seller of indulgences, was born at Leipzig about 1455, and in 1489 entered the Dominican order. His ability and success as a preacher led to his being entrusted in 1516 with the charge of preaching an indulgence in favour of contributors to the fund for building the church of St Peter's at Rome (see Indulgence). It was in opposition to him that Luther published his celebrated theses, on the 31st October 1517. Tetzel published counter-theses and detailed replies, but was himself severely rebuked by the papal delegate Miltitz, for the extravagance in statement and other improprieties which had brought so much scandal upon the church. His personal character was the subject of controversy. He died of the plague at Leipzig in August 1519.

There are (hostile) Lives by Hofmann (1844) and Korner (1880), and from the Catholic point of view by Gröne (2d ed. 1860) and Hermann (2d ed. 1883). See also Kayser, *Geschichtsquellen über Tetzel* (1877).

Teutoburger Wald. See Arminius.

Teutonic Knights, one of the three military-religious orders of knighthood founded during the period of the Crusades. Certain merchants of Bremen and Lübeck, witnessing the sufferings of the wounded Christians before Acre in 1190, were so moved with compassion that they erected tent-hospitals for them, and provided for surgical and nursing attendance. There had been a German hospital in Jerusalem from 1128 to 1187; and the new arrangement at Acre was in some sort a continuance of this, being called the Hospital St Mary of the Germans in Jerusalem. The new hospital, the attendants and founders of which formed themselves into a monastic order with the same rules as the Knights Hospitallers of St John, found a patron in Duke Frederick of Swabia, and through him secured the countenance of his brother, the Emperor Henry VI., and the confirmation of the pope (1191). Seven years later it was converted into a knightly or military order; and the change was stamped with the papal approval in 1199. The knights, in addition to the usual monastic vows, bound themselves to tend the sick and wounded and wage incessant war upon the heathen. Their distinguishing habiliment was a white mantle with a black cross. The chief officer of the order was the grand-master or 'high-master,' who was assisted by five other dignitaries. The chapter consisted of these six officers in conjunction with

the provincial masters. The minor districts and individual castles were governed by commanders, who constituted also the respective provincial councils. There was, moreover, a class of 'serving brothers,' who performed menial offices about the hospitals; and to these were added in certain places a class of inferior female domestics called 'half-sisters.'

About the year 1225 the Duke of Masovia (in Poland) invited the Teutonic Knights to come and help him against the heathen Prussians. The grand-master, Hermann von Salza, sent a body of knights, who experienced little difficulty in establishing themselves in the territories of the heathen. Twelve years later they were strengthened by the absorption into their order of the Brethren of the Sword, a military order which had been formed to convert to Christianity with the sword the Livonians, Esthonians, and Courlanders. At length the successive encroachments of the knights roused the Prussians to bitter opposition. A fierce warfare was then carried on for nearly a quarter of a century; but by 1283 the knights were masters of the territory lying between the Vistula and the Memel, and as heirs of the extinct Brethren of the Sword they had also extensive possessions in Livonia and Courland. In 1309 the executive officers of the order established themselves in the great castle of Marienburg, near the Vistula. After subduing the Prussians, the order entered upon a hundred years' contest against the Lithuanians. But a most serious blow was struck at the knights by the conversion of the Lithuanians to Christianity and the accession (1386) of their prince to the throne of Poland. From this time, having lost their main *raison d'être*—fighting against the heathen—the order began to decline. During the period of its prosperity, however, it had acted as the principal force in the politics of the Baltic countries; and both by its own exertions and by the encouragement it gave to the Hanseatic traders it was the means of spreading German civilisation and manners throughout what are now the Baltic provinces of Russia. The order suffered an incalculable loss of prestige through the terrible defeat inflicted upon them by the Poles and Lithuanians at Tannenberg in 1410. A desperate attempt to recover their power resulted (1466) in the loss of West Prussia and the alienation of the esteem and affection of their subjects in East Prussia, which they could only retain as a fief of Poland. In 1525 the order was secularised; its grand-master, Albert of Brandenburg-Anspach, being created hereditary duke of Prussia under the suzerainty of Poland. The headquarters of the order—for it still possessed several estates scattered throughout the German empire and in one or two other countries—was fixed at Mergentheim in Swabia, and its possessions were reorganised in twelve bailiwicks. Thus it existed until 1801, when the estates west of the Rhine were annexed by France; in 1809 the order was entirely suppressed by Napoleon in all the German states. This left only a couple of bailiwicks in Austria and one at Utrecht; and these still exist, severely aristocratic in both countries. The Austrian branch, reorganised in 1840, justifies its existence by maintaining an organisation for the care of the wounded in war.

See Voigt, *Geschichte des deutschen Ritterordens* (1859); Lohmeyer, *Geschichte von Ost- und West-Preussen* (1880); and Perlbach, *Statuten des Deutschen Ordens* (1890).

Teutons, a group of peoples speaking Teutonic tongues, an important division of the Aryan (q.v.) family of languages. The name is derived from the ancient Teutones (and is a form of the modern German *Deutsch*, O. H. Ger. *Diutisc*, or Gothic *Thiudisko;* see GERMANY). The Teutonic stock of nations, as they exist at the present day, is divided into two principal branches: (1) The Scandinavian, embracing Danes, Swedes, Norwegians, Icelanders; and (2) the Germanic, which includes, besides the German-speaking inhabitants of Germany proper (see GERMANY) and Switzerland (q.v.), also the population of the Netherlands (the Dutch), the Flemings of Belgium, and the descendants of the Angles, Saxons, and Jutes in Great Britain, together with their offspring in North America, Australia, and other British colonies—the English-speaking peoples of the world. It is necessary in this case, as in all similar cases, to guard against making language the sole test of race. In many parts of Germany where German now prevails Slavic dialects were spoken down to recent times, and in some places are not yet quite extinct. And in Great Britain it is unreasonable to suppose that the Anglo-Saxon invaders exterminated the native Celtic population, or even drove more than a tithe of them into Wales and the Highlands. The mass undoubtedly remained as subject serfs, learned the language and customs of their masters, and gradually amalgamated with them; so that, in point of blood, the English are perhaps as much Celtic as Teutonic. The same remark applies more strongly to Scotland and Ireland than to England; and the mingling of races in the United States has been very great, although the non-Teutonic elements have been dominated and assimilated. See the articles on the several Teutonic lands; EUROPE, Vol. IV. p. 464; ETHNOLOGY; and (for the languages) PHILOLOGY.

Teviot. See ROXBURGHSHIRE.

Tewfik Pasha, MOHAMMED, Khedive of Egypt, was born in 1852, the eldest son of Ismail Pasha, and succeeded on his father's abdication in 1879, in virtue of the arrangement of 1866 between Ismail and the Sultan. The chief events of his reign—the insurrection of Arabi, the war with the Mahdi, the pacification of the Soudan frontiers, and the steady improvement of the condition of Egypt under English administration—have been indicated at EGYPT. Tewfik, a pious Moslem, utterly alien to his father's love of luxury and extravagance, was throughout loyal to his engagements with Britain. He died of the sequelæ of influenza, 7th January 1892, and was succeeded by his eldest son Abbas.

Tewkesbury, a quaint old market-town of Gloucestershire, on the Avon at its confluence with the Severn, 9 miles NNW. of Cheltenham, 10 NNE. of Gloucester, and 15 S. by E. of Worcester. On the site of the cell of the hermit Theoc, from whom the place got its name, was founded in 715 a monastery, refounded in 1102 by Robert Fitzhamon as a great Benedictine abbey. Its noble church, consecrated in November 1123, measures 317 feet by 124 across the transepts, and remains essentially Norman, in spite of later additions—Early English, Decorated, and Perpendicular. It was restored by Scott in 1875–79. Special features are the west front and the massive central tower, 132 feet high. Many of the Clares, Despencers, Beauchamps, and other lords of Tewkesbury are buried here, as also the murdered Prince Edward and (possibly) Clarence; and in 1890 a tablet was erected to Mrs Craik, the scene of whose *John Halifax* is laid in Tewkesbury. The place has also a town-hall (1788), a corn-exchange (1856), Telford's iron bridge over the Severn (1824), with a span of 176 feet, a free grammar-school, &c. The thick mustard Falstaff speaks of is a thing of the past, and the trade is chiefly agricultural. Within half a mile was fought (4th May 1471) the famous battle of Tewkesbury, in which the Yorkists under

Edward IV. (q.v.) gained a crowning victory over the Lancastrians. Incorporated by Elizabeth in 1574, Tewkesbury returned two members to parliament from 1609 till 1867, and then one till 1885. Pop. (1851) 5878; (1891) 5269.

Texas is the extreme south-western state of the American Union. It extends farther south than any of the United States except Florida, and lies in 25° 51′—36° 30′ N. lat. and 93° 27′—106° 43′ W. long. Its very irregular boundary consists largely of natural lines formed by rivers and the Gulf of Mexico. Oklahoma and Indian Territory lie to the north, Arkansas and Louisiana to the east, Mexico and the Gulf to the south, and New Mexico to the west. Texas not only is the largest state in the Union, but forms, with its area of 265,780 sq. m., nearly 9 per cent. of the total area of the United States, exclusive of Alaska. It is as large as New England, the Middle Atlantic States, Ohio, and Illinois combined, or larger than either France, Austria-Hungary, or Germany, and more than twice as large as the British Isles. Its extreme length is about 900 miles, and its greatest breadth 750; the coast-line is 400 miles long. The surface of Texas is greatly diversified. From the low, flat prairie lands along the coast the land rises in a series of gradual elevations till it reaches the plateau and mountains of the distant west, where some of the peaks attain a height of 5000 feet above the sea. The coast is low and sandy. From the mouth of the Sabine River to that of the Rio Grande there extends a fringe of low islands and peninsulas, separated from the mainland by lagoons several miles in width. These islands are characterised by sand-dunes which rise about 20 feet above the beach. Padre Island, extending north from the mouth of the Rio Grande, is more than 100 miles in length. The alluvial coast-belt, extending from 25 to 60 miles inland, comprises both fertile lowlands and stretches of barren soil. In the waste portions there are extensive areas of cactus and thorny mesquite chaparrals. A white, sandy tract reaching south and west from Corpus Christi Bay to the Rio Grande is known as 'the desert.' Beyond this coast-plain lies a terrace of rich rolling land called the 'prairie belt.' In the eastern prairie sections there are extensive timber regions of live oak and deciduous forest trees, which cover an area greater than that of the state of Kentucky, not including two wide forest-belts called 'cross-timbers,' which extend southward from the Red River. To the north and west of the prairies the land rises and presents a rough, broken surface, with occasional bluffs. Much of the soil is fertile, and nearly all of it is excellently adapted for grazing. On the southern border of the plateau the elevation is about 1000 feet, but a height of 2000 feet is reached as the ascent continues toward the arid *mesas* of the *Llano Estacado* and the base of the Rocky Mountains, from which some outlying ridges extend into the state.

Copyright 1892 in U.S. by J. B. Lippincott Company.

There is every variety of soil, from the fertile lands of the river-bottoms and prairies to the sterile sand of the southern desert. The coast-prairies have in general a sandy loam. In those of the interior there are heavier brown and black loams, while in the northern part of the state there are great areas of red lands. In the south and south-east, where fortunately much of the best land is located, the rainfall is ample, but the supply in the west and north-west is less reliable. However, it has been shown that even the *Llano Estacado*, or Staked Plains, which were once considered utterly uninhabitable, are capable of supplying plenty of water for irrigation by the use of artesian wells and windmills. The northern winds are usually dry, the rain comes almost entirely from the south-west, and the winter months are generally the driest. The best water-supply is found in the timber-lands. In a state extending through eleven degrees of latitude there is naturally found a considerable range of temperature. The climate on the coast-plains is semi-tropical, but is tempered by the winds from the Gulf. A dry, healthful climate prevails in the middle region, and the north experiences cool winters, with heavy snowstorms at times. The air of western Texas is so dry that meats are perfectly preserved in the open air without salt, and carcases of dead animals on the plains emit no odour. A notable feature of Texas climate is the 'norther,' which is a sudden and extreme change of temperature produced by a rush of cold wind from the north. This unwelcome visitor arrives usually unannounced, except for the fact that its coming is frequently preceded by a spell of warm weather. It ordinarily remains for three days, and the fall in temperature is often as much as 30°. The drainage of Texas is received by the Gulf of Mexico. The Red and the Arkansas rivers convey the waters of the northern part of the state to the Mississippi. The other streams flow directly into the Gulf. The Red and Sabine rivers and the Rio Grande form parts of the boundary line. Within the state the most important rivers are the Trinity, the Brazos, and the Colorado. With the exception of the Rio Grande, the Brazos, and the Sabine, nearly all the streams discharge their waters by means of large estuaries, from which steep clay banks rise for some height to the level of the prairie above. Knowledge of the details of the geological structure of Texas is quite imperfect. The coast-plains and prairies are of recent alluvial formation. Beyond these is a broad strip of Tertiary deposits, and farther inland the country belongs to the Cretaceous period, except in the central regions, which are penetrated from the north by contiguous arms of Jura, Trias, and Permo-Carboniferous formations. Large beds of coal underlie portions of the state. The coal-measures are estimated to occupy an area of about 10,000 sq. m., besides which there are extensive beds of brown lignite. There are vast deposits of iron ore, and tin and other metals are also found. Building-stones of excellent quality occur in many districts, and the supply of lime, gypsum, and salt is inexhaustible.

Agriculture and stock-raising have been the leading occupations of Texas. Rather more than one-half of the entire area is practically uninhabited, but settlements are encroaching each year upon the unreclaimed districts, and the primitive methods of the cattle-ranges are rapidly disappearing. Texas is pre-eminently a cattle-breeding state. The abundance of suitable pasturage and the genial climate give it advantages over many other sections. The old custom of sending young cattle in enormous 'drives' into other states, where they were sold to be fattened, is becoming a thing of the past. The owners are more and more 'ripening' their own cattle, thereby securing better prices, and opening the way for manufacturing industries connected with the preparation of beef and hides, and for the direct export of beef abroad from Galveston and New Orleans. Texas ranks first in cattle-raising, and in the number of sheep, horses, mules, and swine it is almost without a rival. The breeds of all varieties of live-stock have been of late very much improved. Wool and dairy-produce are important staples. Since 1883, when its crop surpassed that of Mississippi, Texas has been the leading cotton state. Wheat is an important crop, and the other grains are extensively culti-

vated. Sugar and rice yield abundant harvests along the coast, and fruits in great variety are produced in the southern sections. The principal sugar district is the 'sugar-bowl' in the Brazos delta. A fearful hurricane and high tide in September 1900 destroyed Galveston, devastating the country around; 4000 lives were believed to have been lost, and property ruined to the amount of $10,000,000. In 1901 very rich springs of petroleum were tapped in the district about Beaumont, 80 miles NE. of Houston. The largest towns are Austin (the capital), San Antonio, Dallas, Galveston, Houston, Fort Worth, Waco, Laredo, Denison, and El Paso. There is a large available fund for education, to which the proceeds of the sale of over 50,000,000 acres of land are to be added; this sum will be more, rather than less, than $100,000,000. The state supports several normal schools, and a state university at Austin.

The earliest settlements in Texas were made in 1685. The country formed part of the Spanish province of Mexico, which in 1822 threw off the yoke and became a republic. On December 20, 1835, Texas declared itself independent of Mexico, and in 1836 Houston (q.v.) was made president. In 1845 Texas, with an area of 375,000 sq. m., was annexed to the United States. All its territory except that now enclosed within its borders was ceded to the United States in 1850 for the sum of $10,000,000. Texas had maintained continued war with Mexico, and its annexation was the prime cause of the war between that country and the United States. The state seceded from the Union February 1, 1861, and re-entered it April 16, 1870. The growth of Texas has been phenomenal, and, though it ranks seventh among its sister commonwealths in population, it is in many aspects still in a transition period. There were less than 300 miles of railway in operation in 1870, and in 1899 about 9000. In 1870 Texas had a population of 818,579, in 1880 of 1,591,749 (393,384 coloured), and in 1890 of 2,235,523 (492,837 coloured).

See Histories of Texas by H. Yoakum (2 vols. 1856), W. C. Baker (1873), H. S. Theall (1879), and H. H. Bancroft (1885).

Texel, an island belonging to the province of North Holland, at the entrance to the Zuider Zee. It is separated from the mainland by a narrow strait, called the Marsdiep, contains about 35,000 acres of arable and pasture lands, and has a population of about 6500 inhabitants, who keep some 35,000 sheep, famous both for their wool and their cheese. The Marsdiep channel or part of it is also often called the Texel; and here or hereabouts many important naval battles have been fought. Blake defeated Tromp and De Ruyter in 1653; Prince Rupert fought De Ruyter in 1673; Duncan blockaded the Texel (for a time with a single ship) in 1797; and a Dutch fleet of twelve ships of war and thirteen Indiamen surrendered to Admiral Mitchell in 1799.

Textiles, fabrics produced by weaving. See the articles in this work on Weaving, Spinning, Cotton, Fibrous Substances, Hemp, Linen, Jute, Silk, Wool, &c.; also on Bleaching, Calico-printing, Dyeing, &c.

Tezcuco, a city of Mexico, on the east shore of the salt lake of the same name, 25 miles by rail ENE. of Mexico city. The ancient *Acolhuacan*, once the chief seat of Aztec culture, it still contains traces of old palaces and of a noble aqueduct, and is now the seat of glass-works. In the great drainage scheme for the valley of Mexico and Tezcuco, the sewage is carried off by a tunnel of 6½ miles and a canal of 30 miles. The salt lake has an area of 92 sq. m. Pop. 15,000.

Thackeray, William Makepeace, born 18th July 1811, died 24th December 1863. The Thackerays were originally a race of small landholders settled at Hampsthwaite in Yorkshire. In fullness of time, as was often the case with such families, the younger sons began to leave their native village and try their fortunes in other walks of life. In 1711 we find the Rev. Elias Thackeray of Christ's College, Cambridge, established in the rectory of Hawkswell, Yorkshire. His nephew, Thomas Thackeray, became headmaster of Harrow School and the father of sixteen children; the youngest of whom, William Makepeace, was the grandfather of the novelist. This William Makepeace Thackeray went to Bengal in the East India Company's service, from which he retired in 1777 with a fortune. The fourth of his twelve children, Richmond Thackeray, born in 1781, was the father of the novelist. Richmond Thackeray also went to India in the Company's service, where he married Miss Anne Becher, a renowned Calcutta beauty, the daughter of a fellow civilian.

Copyright 1892 in U.S. by J. B. Lippincott Company.

William Makepeace Thackeray, the only child of the marriage, was born on the 18th July 1811 at Calcutta. When he was five years old his father died; and soon after his mother married Major Carmichael Smyth, of the Bengal Engineers. She lived to survive her son. There were no children of the second marriage. On the death of his father, Thackeray, then a child of five years old, was sent home. He lived partly under the care of an aunt, Mrs Ritchie, who is recorded to have been surprised to find that her husband's hat fitted the little boy. At eleven he was sent to the Charterhouse, where he remained six years. Innumerable passages in his books prove that his schooldays had as important an influence on his art as the more adventurous boyhoods of Sterne and Dickens had on theirs. It should be added that the broken nose so conspicuous in all Thackeray's caricatures of himself was the accident of a school fight. While Thackeray was at school his parents returned from India and settled near Ottery-St-Mary in Devonshire, which is made the scene of the earlier chapters of *Pendennis*. In 1829 Thackeray was entered at Trinity College, Cambridge. He left the university after two years without taking his degree; but except from the academical point of view his time was not wasted. Without being a scholar, he acquired a literary knowledge of the classics, and he gained all those indirect advantages which distinguish Oxford and Cambridge from other seats of perhaps purer learning. For one thing, Cambridge fixed his social status. Though afterwards he was to consort with Bohemians and other strange acquaintances into whose company a man is forced by adversity, he was never a Bohemian, and always faithful to the traditions of the class in which he was born and bred. It was at Trinity that Thackeray first appeared in print, the work being a burlesque of the prize poem on the subject of *Timbuctoo*, which had been won by Alfred Tennyson. 'A poem of mine,' he writes to his mother, 'hath appeared in a weekly periodical, here published and called the *Snob*. . . . Young had a pleasant wine party at which for a short time I attended. *Timbuctoo* received much laud. I could not help finding out that I was very fond of this same praise. The men knew not the author, but praised the poem.'

On leaving Cambridge Thackeray travelled for two years, in Germany for the most part, and on his return determined to go to the bar. It was necessary for him to choose a profession, as his fortune did not exceed some £500 a year. This, moreover, was soon diminished by losses from the

failure of an Indian bank; and he was probably glad of an excuse to abandon the law for the more immediately remunerative pursuit of literature. From the very first he had a passion for drawing and literary composition, his fancy in both running to caricature. Early in 1833 he became a regular contributor to the *National Standard and Weekly Journal of Literature, Science, Music, Theatricals, and the Fine Arts*, a weekly journal, price twopence, edited by F. W. N. Bayley, Esq., a then well-known journalist. With the nineteenth number Thackeray took the editorship, and subsequently became the proprietor also. 'My *National Standard*, as usual,' he writes from the Garrick Club. 'It has increased in sale about twenty in the last month. At this rate I shall be ruined before it succeeds.' The paper finally came to an end after little more than a year's existence. But art, not literature, was Thackeray's real ambition at that time. 'I think,' he says in a discussion of plans which followed the family losses, 'I can draw better than do anything else, and certainly I should like it better than any other occupation.' And towards the end of 1833 he joined his parents at Paris to study painting seriously. 'I am sure we shall be as happy here as possible, and I believe I ought to thank Heaven for making me poor, as it has made me much happier than I should have been with the money. I spend all day now, dear mother, at the Atelier, and am very well satisfied with the progress I make.' But Thackeray was not destined to realise the ideals of the envied 'J. J.' of *The Newcomes*. Money was wanted, and could always be earned by the pen. It is curious to observe that Thackeray, who must, one would have thought, have been conscious of his genius for fiction, was content for years to work in the humble and practical walks of journalism. How much or what he wrote at this period is not known, but it is certain that his portrait appears in a conspicuous place in the group by Maclise of the contributors to *Fraser* which was published in the magazine for January 1835. It was at this time too that he made his famous application to illustrate *Pickwick*.

In 1836 Thackeray married Isabella, daughter of Colonel Shawe, of the Indian army. His bride brought him no fortune, and he must have known that his marriage plunged him in grim earnest into the battle of life. Years afterwards, writing to a friend, he says: 'I married at your age with £400, paid by a newspaper which failed six months afterwards, and always love to hear of a young fellow testing his fortune bravely in that way.' The newspaper which failed was the *Constitutional*, the property of the Metropolitan Newspaper Company, of which Thackeray's stepfather was chairman. It was started to rival the leading daily papers, but it only existed from September 1836 to July 1837, when it failed, carrying with it the rest of the fortune of Thackeray and his parents. During the first months of the life of the *Constitutional* Thackeray acted as Paris correspondent. Early in 1837 he moved with his wife to London, living first in Albion Street, Hyde Park, where his eldest daughter was born, and then at Great Coram Street. The marriage was a very happy one, and, in spite of the failure of the *Constitutional*, work was abundant and the future promising. Thackeray was writing regularly in the *Times*, which was then no less important than it is now, and also in the *New Monthly*, *Fraser's Magazine*, and in Cruikshank's *Comic Almanacks*. It is perhaps worth mentioning that in the *Times* he wrote the review of Carlyle's *French Revolution*. In 1838 was born a second daughter, who died in infancy; and in 1840 a third, Mrs Leslie Stephen, who died in 1875. The illness which followed the birth of the third daughter affected Mrs Thackeray's mind, and she never recovered, though she lived till 1894. This misfortune broke up the home. The children were sent to Paris to their grandmother, and for a year Thackeray travelled about with his wife from watering-place to watering-place, as the doctors recommended, but without result. The truth had to be realised, and Thackeray went back to London, alone and worse than alone. But his genius was by this time asserting itself, and, though his success in the vulgar sense of the word was not assured till the publication of *Vanity Fair*, not a year passed without his contributing to the magazines—in addition to a great mass of journalism—work the quality of which is not now disputed. In 1840 appeared his first book, *The Paris Sketch-book*, a series of reprints, followed in 1841 by the *Comic Tales and Sketches*, which contained the *Yellowplush Papers* from *Fraser*, *Major Gahagan* from the *New Monthly*, and the *Bedford Row Conspiracy*. These publications were a failure. In the same year the *Hoggarty Diamond* and the *Shabby Gentcel Story* appeared in *Fraser*, followed by *Barry Lyndon* and *Men's Wives* in the same magazine. In 1843 and 1846 appeared respectively the *Irish Sketch-book* and *Cornhill to Cairo*. 'I can suit the magazines,' he wrote to a friend, 'but I can't hit the public, be hanged to them.' However, the magazines, and more especially *Punch*, the staff of which he joined in 1842 both as writer and drawer of pictures, enabled him in 1846 to set up house again; and he brought his family over from Paris to Young Street, Kensington Square. He was installed in this new home when the publication of *Vanity Fair* began, in monthly numbers, early in 1847; at which time he was also bringing out the *Snob Papers* in *Punch*. *Vanity Fair* was not at first a success. The earlier numbers failed to attract attention, and there was even a talk of stopping the publication altogether. Towards the end of the year, however, luck changed. Thackeray himself used to say that it was the success of the first of his Christmas books, *Mrs Perkins's Ball*, which made him fashionable. But, whatever the cause, there was no doubt about the fact. Every month the sale increased, and by the time *Vanity Fair* was finished it had made the author's reputation. Thackeray was no longer the servant, but the master of the public.

Vanity Fair had two results for Thackeray—the first, that he became a lion of society, and for some years enjoyed or endured the consequences of his position; the second, that he had no longer to look to *Punch* and the magazines for bread. The last number of *Vanity Fair* appeared in July 1848. It was followed in November of the same year by the first instalment of *Pendennis*. *Pendennis* was followed by *Esmond*, which was published in three volumes in 1852; and Thackeray then sailed for America with his lectures on the humorists, which he had already delivered with great success in London. On his return in 1853 *The Newcomes* began to appear; and on its conclusion in 1855, after the publication of *The Rose and the Ring*, which was begun at Rome for the amusement of his children, Thackeray again made a journey to America with his lectures on the 'Four Georges.' In 1857 he tried to get into parliament, standing for the city of Oxford as a Radical against Mr Cardwell, but was defeated by a majority of seventy-three. During this year and the next the *Virginians* came out. On the 1st January 1860 the *Cornhill Magazine* made its appearance, with Thackeray as editor. To the *Cornhill* he contributed *Lovel the Widower* and *Philip*, which seem to have been written somewhat against the grain, though *Philip* is specially interesting for the auto-

biographical element which it contains. But if the *Cornhill* did not bring out Thackeray's best work as a novelist, it furnished the occasion for the *Roundabout Papers*, the desultory form of which was a source of strength, not of weakness, and showed his powers at their best. In 1862 he gave up the editorship of the *Cornhill*, not being equal to the task of refusing manuscripts; but he continued to work for the magazine, and in that year he moved into a new house which he had built on Palace Green, Kensington. He always had a taste for bric-a-brac, which was not so fashionable then as now; and this house was the first built in London in red brick, in the style of Queen Anne, which has since taken such developments throughout the country. Here he began to write *Denis Duval*, which, so far as he had completed it when he died, promised to be as great as anything he had done. But his health, which had practically been broken by a fever caught in Rome in 1855, was bad. No immediate danger was feared, but he was found dead in his bed on the morning of Christmas Eve, 1863. He was buried in Kensal Green. His bust is in Westminster Abbey, in Poets' Corner.

The best commentary on Thackeray's books is furnished by the story of his life, as will be seen, it is hoped, even from the short account we have given. The qualities of his work speak for themselves to the least experienced of those who read him, and little need be said by way of exposition. It may be worth while, however, to point out that as an artist he is unsurpassed by any novelist, either in style or in his powers of description and of character drawing, or in the crowning gift of telling a story. His ideal of the novel was, like Fielding's, that it should be not an affair of plot or a form of idyll, but a prose epic; and if this ideal has ever been approached it is surely in *Vanity Fair* and *The Newcomes*. In the second place, it is worth dwelling for a moment on Thackeray's extraordinary sense of fun. So much of his humour is tinged with irony that readers sometimes fail to observe what sources of natural laughter are in his books, and what an unrivalled exhibition they give of purely comic power. Lastly, a word must be said about his satire. There will always be a class to whom Thackeray must appear as attacking the very essence of human society and turning to ridicule its most useful and ornamental members. Critics of this school can naturally never forgive him or sympathise with his genius. There is another class which takes a different view, and considers that what Thackeray calls 'snobbishness' is neither an essential nor a necessary part of human nature. Which of these two opinions may be correct it is impossible to prove; but if one turns from what Thackeray ridiculed to what he admired, it must be admitted that for a satirist his views of life are strangely sentimental. No one, it is safe to assume, ever read *Vanity Fair* without preferring Rawdon Crawley to his brother Pitt. But if those who think the *Book of Snobs* unjust will consider the reasons for this preference, they will understand why Thackeray disliked some things and why he cared for others.

No authorised biography of Thackeray has ever been published. There is a good short Life in the 'Great Writers' series (1891), by Mr Herman Merivale and Mr F. T. Marzials. In 1899 Mr Lewis Melville published a Life in two volumes. Some of his letters were published in *Scribner's Magazine* (1887). Many of his drawings may be found in *The Orphan of Pimlico* (1875). The best portraits of him are by Samuel Lawrence; there was also a vigorous statuette by Boehm. See also Mrs Richmond Ritchie's *Chapters from Some Memoirs* (1894) and her introduction to the *Biographical Edition* of the works (13 vols. 1898–99); Eyre Crowe, *Thackeray's Haunts and Homes* (1897); and Sir W. W. Hunter, *The Thackerays in India* (1897).

His eldest daughter, ANNE ISABELLA, novelist, is better known still as 'Miss Thackeray' than by her married name, Mrs Ritchie. Born in London in 1837, she passed her childhood in Paris, her girlhood at Kensington, and first appeared as an author in vol. i. of the *Cornhill* (1860) with 'Little Scholars.' To this sketch succeeded a dozen or more volumes of novels, tales, biographical essays, &c., of which may be mentioned *The Story of Elizabeth* (1863), *The Village on the Cliff* (1867), *Old Kensington* (1873), *Miss Angel* (1875, its heroine Angelica Kauffmann), *Mrs Dymond* (1885), *Records of Tennyson, Ruskin, and Browning* (1892), and her dainty modern recasts of such old-world stories as 'Bluebeard' and 'Cinderella.' Tender, delicate, harmonious, her books are feminine as very few women's books, and are just for that reason delightful. In 1877 she married her cousin, Mr Richmond Thackeray Ritchie.

Thais, an Athenian courtesan, famous for her wit and beauty, who was in Asia with Alexander the Great, and according to Cleitarchus—a doubtful authority—induced him, when flushed with wine, to fire the palace of Persepolis (q.v.). After his death she had several children by Ptolemy Lagi.

Thalberg, SIGISMOND, one of the most eminent pianists of the century, was born in 1812 at Geneva, where he received his early education under the careful supervision of his mother, the Baroness Wetzlar. At the age of ten he was removed to Vienna, where he continued his studies, showing a special aptitude for languages and music, in which subjects he received instruction from the best masters, as his father destined him for a diplomatic career. Thalberg's first appearance as a pianist was at the age of fourteen, when he played at an evening party at Prince Metternich's. This success was followed up by numerous appearances in Paris, until, overcoming his father's scruples, he was allowed to abandon diplomacy for music. He made tours in 1839 through Belgium, Holland, England, and Russia, and afterwards through Spain, Brazil, and North America, finally settling down at Naples in 1858, where he died on 27th April 1871. Thalberg married Madame Boucher, daughter of the celebrated Lablache and widow of a Parisian artist. His musical compositions comprise more than ninety numbers, principally fantasias and variations. His operas *Cristina* and *Florinda*—the latter played before the Queen in London in 1851—were absolute failures. As a pianist, in graceful and brilliant execution and in manual dexterity, he had scarcely a rival. It is said that the under tips of his fingers were 'real little cushions,' which were used with such effect in producing wonderful legatos that Liszt once made the remark: 'Thalberg is the only artist who can play the violin on the keyboard.'

Thales, an early Greek philosopher, founder of the Ionic or physical school of philosophy, and one of the Seven Wise Men, was a native of Miletus, in Asia Minor, and flourished towards the close of the 7th century B.C. He is said to have recommended the Ionians, who were menaced by the Persians, to form a federation against their powerful enemy, and to select Teos as the capital, and later we are told he induced the Milesians to withdraw from a union with Crœsus against Cyrus. He is also said to have predicted the eclipse of the sun which happened in the reign of Alyattes. Thales is regarded by some as the first Greek that speculated on the constitution of the universe. According to him the original principle of all things is water, from which everything proceeds, and into which everything is again resolved. In connection with this doctrine he had, it seems, some idea of a soul or force in water productive of all the phenomena we see.

Thali'a. See MUSES.

Thallium (sym. Tl, equiv. 203·6) is a metal which derives its name from the Greek word *thallos*, 'green,' because its existence was first recognised by an intense green line appearing in the spectrum of a flame in which thallium is volatilised. It was discovered by Mr Crookes in 1861 in the seleniferous deposit of a lead chamber of a sulphuric-acid factory in the Harz Mountains; and it was soon obtained in large quantities by M. Lamy. Thallium is slightly heavier than lead—a metal which it resembles in its physical properties. It is very soft, being readily cut with a knife or drawn into wire; and its freshly-cut surface exhibits a brilliant metallic lustre and grayish colour, somewhat between those of silver and lead. In contact with the air it tarnishes more rapidly than lead, and becomes coated with a thin layer of oxide which preserves the rest of the metal. It fuses at 554° (290° C.), and at a red heat becomes volatilised. The metal and its compounds give a bright green tint to colourless flames; the spectrum of thallium is marked by a single sharply-defined green line. It is used to produce a green light in firework displays, and is employed to render glass highly refractive. The metal can best be preserved free from oxidation by being covered with paraffin and kept below water. Thallium forms a number of compounds, including three oxides.

Thallus, a vegetative body showing little or no differentiation into leaf, stem, and root, and characteristic of the *thallophytes* or lower Cryptogamia (q.v.), including Algæ (q.v.), Fungi (q.v.), and Lichens (q.v.). Even in the higher members of the ascending series the thallus has neither true vessels nor woody tissue.

Thames, the most important river of Great Britain, flows east-south-east across the south portion of the country. Its four head-streams—the Thames or Isis, Churn, Coln, and Leach—rise on the south-east slope of the Cotswold Hills, the upper part of the main stream being often called Isis (a quasi-classical form of *Ouse*) and not Thames until after it receives the Thame near Dorchester. The Thames or Isis flows east-north-east for about 35 miles, when, curving south-east, it passes Oxford, and flows on to Reading, where, after receiving the Kennet from the west, it again changes its course; and with a generally eastward course it passes Windsor, Eton, Teddington (the lowest of thirty-three locks between here and Oxford, and the highest point to which the tide ascends), Richmond, London, Woolwich, and Gravesend, a few miles below which it expands into a wide estuary, and enters the North Sea. On its tidal estuary, and on the fact that like most British rivers it has no delta, depends the river's importance as a navigable waterway; the navigation is, however, somewhat impeded by what has been called a 'submarine delta'—banks formed of river sediment. From Lechlade to the Nore the direct length is 120 miles, and with the windings may be 250 miles (112 from Oxford to London Bridge); the area of its basin is 6100 sq. m. Throughout the greater part of its course it forms the boundary-line between several of the southern counties. Passing Cricklade, it forms part of the northern boundary of Wilts, and below this point it separates the counties of Oxford, Buckingham, Middlesex, and Essex on the north from those of Berks, Surrey, and Kent on the south, except certain outlying bits of some of these counties. Its chief affluents are the Windrush, Cherwell, Thame, Colne, Lea, and Roding, on the left; and the Kennet, Loddon, Darent, Mole, Wandle, and Medway, on the right bank. At London Bridge the width of the river is about 290 yards; at Woolwich, 490 yards; at Gravesend Pier, 800 yards; three miles below Gravesend, 1290 yards; and at its mouth, between Whitstable and Foulness Point, about 8 miles below the Nore, it is 18 miles across. At the Nore Light, the commonly reputed mouth of the Thames, the breadth is nearly 6 miles. The river is navigable for barges to Lechlade, and it is connected with several important canals, by means of which it maintains communication with the west and south coasts, and with the interior of the country. Vessels of 800 tons can reach St Katharine's Docks; much larger ones can ascend to Blackwall, 6 miles below London Bridge; and the largest sea-going steamers reach Tilbury Docks, 26 miles below (see DOCKS). The part of the river immediately below London Bridge is called the *Pool;* and the part between the Bridge and Blackwall is called the *Port.* Two embankments have been formed, one since 1864 on the north shore from Blackfriars Bridge to Westminster, and one since 1866 on the south shore from Westminster Bridge to Vauxhall. The river supplies London with much of its drinking-water, and carries most of its sewage to the sea (see WATER-SUPPLY; and SEWAGE, Vol. IX. p. 341). Some of the great bridges which span the river at London are described at BRIDGE.

Though the lower Thames has been converted into a sewer, in virtue of this same part of its course the river ranks as the chief commercial highway of the world. Above London the scenery is rich and beautiful, though not romantic or picturesque, the numerous islands or eyots lending a peculiar charm. The Thames is the best beloved of English rivers for those who boat for pleasure. For boat-racing, it divides the honours with the Tyne (see ROWING); the Thames watermen are renowned in song and story. Since Spenser's days 'the silver-streaming Thames' has been sung by England's poets; Herrick calls it 'Silver-footed Thamesis;' Denham's apostrophe (quoted at DENHAM) has long been famous; and Pope has gracefully word-painted much of the scenery of its banks. It was (now alas! long since) famous for its salmon, as it still is for other anglers' fish; below London flounders and eels are still plentiful, while the whitebait is almost peculiar to the lower Thames.

The Thames has a copious bibliography of its own (comprising upwards of seventy entries in Anderson's *British Topography* and upwards of 150 in *Notes and Queries* for 1884). Many of these works are richly illustrated. Of comparatively recent ones may be mentioned that by Mr and Mrs S. C. Hall (1859; new ed. 1878), Robertson (1874), Huxley (*Physiography,* 1877), Farren (1881), Law (1881), George D. Leslie, R.A. (1881; new ed. 1888), Church (1885), Herring (1885), Cassell (*Royal River,* 1886), W. Black (*Strange Adventures of a House-boat,* 1888), Justin M'Carthy and Mrs Campbell Praed (1890), Senior (1890), Mr and Mrs Pennell (1891); Wyllie and Allen, *The Tidal Thames* (1894); and the annual *Dictionary of the Thames* (since 1881), by Charles Dickens, junior.

Thames (or GRAHAMSTOWN), New Zealand, a gold-mining town of 4444 inhabitants, on an inlet of Hauraki Gulf, 40 miles SE. of Auckland.

Thamugas, 'the Numidian Pompeii,' near the Aures Mountains, and 22 miles from Batna, which is half-way by rail from Constantine to Biskra. Here are in the solitude extensive remains of colonnades, temples, a forum, a triumphal arch in honour of the Emperor Trajan (founder of the city), and numerous statues and inscriptions coming down to the 5th century, when the Roman city was destroyed by the barbarians.

Thana, or NORTH KONKAN (see KONKAN), a British district of India, consisting of the island of Salsette and a strip of coast. The chief town,

Thana, a seaport (pop. 14,846), is 21 miles NE. of Bombay by rail.

Thane (A.S. *thegn*), a member of a class in the old English community that stood distinctly below the old nobility (*eorlas*, &c.), but above the mere landowners or *ceorls*. The word thegn seems to have meant first soldier, then attendant, servant of the king, royal official; and gradually the thanes came to constitute a kind of nobility of service as distinguished from nobility of blood. Finally, however, the ordinary thane was simply a landholder on a larger scale than the ceorl—one who had five hides or more of land—and the dignity was hereditary, the 'king's thane' being a superior class. The thanes nearly corresponded to the Norman knights; and after the conquest they were mostly absorbed into the knighthood. After the reign of Henry II. the name of thane fell into disuse in England. In Scotland, on the other hand, where the title is occasionally used as late as the 15th century, the thane was a hereditary non-military tenant of the crown; and there is no foundation for the notion derived by Shakespeare from Boece, that the Scottish thanes all became earls.

Thanet, Isle of, forms the north-eastern corner of the county of Kent, from the mainland of which it is cut off on the western side by the river Stour and the Nethergong rivulet—the ancient Wantsome channel, completely silted up since the beginning of the 16th century. It is bounded on the N. and E. by the sea, and opens on the south side into Pegwell Bay. It measures 9 miles east and west, and 5 miles north and south, and contains 26,180 acres. On the shores of the island are the well-known watering-places Ramsgate, Margate, and Broadstairs; and on the North Foreland, in the north-east, there is a lighthouse, 85 feet high, visible 19 miles. Pop. (1871) 42,129; (1881) 50,646; (1891) 57,821. See James Simson's *Historic Thanet* (1891).

Thanet Sands. See Eocene System.

Thanksgiving Day, in the United States, is an annual festival of thanksgiving for the mercies of the closing year. Practically it is a national harvest festival, fixed by proclamation of the president and the governors of states, and ranks as a legal holiday. In 1789 the Episcopal Church formally recognised the civil government's authority to appoint such a feast, and in 1888 the Roman Catholic Church also decided to honour a festival which had long been nearly universally observed—though nowhere with such zest as in the New England states, where it ranks as the great annual *family* festival, taking the place which in England is accorded to Christmas. The earliest harvest thanksgiving in America was kept by the Pilgrim Fathers at Plymouth in 1621, and was repeated often during that and the ensuing century; congress recommended days of thanksgiving annually during the revolution, and in 1784 for the return of peace—as did President Madison in 1815. Washington appointed such a day in 1789 after the adoption of the constitution, and in 1795 for the general benefits and welfare of the nation. Since 1817 the festival has been observed annually in New York, and since 1863 the presidents have always issued proclamations appointing the last Thursday of November as Thanksgiving Day.

Thann, a town of Alsace-Lorraine, 13 miles NW. of Mühlhausen by rail. It contains a superb Gothic church, surmounted by a spire of delicate open work, upwards of 300 feet high. Cotton cloths, silks, chemicals, and machinery are manufactured. Pop. 7462.

Tharsis. See Tarshish; and for the modern Tharsis copper-mines, see Rio Tinto.

Thasos, the most northerly island in the Ægean Sea, near the coast of Macedonia. Area, 167 sq. m.; pop. 5200, almost exclusively Greeks. The surface is covered with high, wooded hills (Hypsaria, 3428 feet); indeed Archilochus' description is still applicable—'An ass's backbone overspread with wild wood.' Thasos exports some oil, honey, and timber. In ancient times it was famous for its gold-mines. It was colonised by the Parians, among them the poet Archilochus. It was subdued into obedience to Athens by Cimon (463) and Thrasybulus (407).

Thaumatrope. See Zoetrope.

Theatines, a religious brotherhood of the Roman Catholic Church, which played a very important part in the internal movement for reformation which took place in Central and Southern Italy towards the middle of the 16th century. The founders of this association were a party of friends, Cajetan di Thiene, John Peter Caraffa, at that time Bishop of Theate (from which the Congregation took the name *Theatine*), Paul Consiglieri, and Bonifazio di Colle. Cajetan and Caraffa, in concert with the two other friends named above, having resigned all their preferments, obtained in 1524 a brief of Clement, formally constituting the new brotherhood, with the three usual vows, and with the privilege of electing their superior, who was to hold office for three years. They were forbidden to possess property, and were to subsist entirely upon the alms of the faithful; and yet they were strictly forbidden to beg, or in any way to solicit charitable contributions. Their first convent was opened in Rome, and Caraffa, afterwards Pope Paul IV., was chosen as the first superior. He was succeeded in 1527 by Cajetan, and the Congregation began to extend over Italy, and afterwards into Spain, Poland, Germany, not reaching France till 1644. To their activity, devotedness, and zeal Ranke ascribes much of the success of that remarkable reaction against Protestantism which took place in the later half of the 16th century. Subsequently the Theatine order is confined to Italy. A body of Theatine nuns was established in 1618.

Theatre (Gr. *theatron*, 'a place for seeing,' from *theaomai*, 'I see') means literally any building used for purposes of exhibition; but, popularly, it is generally taken to mean a place devoted to dramatic and musical performances. The classical theatre arose among the Greeks. Its germ was the ring in which dithyrambs and phallic songs were performed by choruses in honour of Dionysus. These were performed in an orchestra or circular dancing place, on all sides of which the spectators were ranged. Later a table was introduced, on which the leader of the chorus stood while he carried on a dialogue with the rest of the choreutæ in the intervals between the choral odes. This was the rudimentary form of the stage. Next an actor, a single actor, was introduced by Thespis, and, as he played many different parts, a tent had to be erected in which he should be able to change his mask and dress. Out of this tent arose ultimately the stage-buildings of the Greeks, which, even after they became elaborate structures of stone, retained the name *skēnē*, 'a booth or tent.' From the remains of various Greek theatres which have been excavated it is possible to reconstruct, at least in its main features, one of these edifices. Fig. 1 shows the design of the theatre at Segesta. The central circle is the *orchestra*, in which the chorus sang and danced, and in the middle of which the altar of Dionysus probably stood. In the oldest theatres the orchestra formed an exact circle, but ultimately the circle was cut on the side next the stage, as

Copyright 1892 in U.S. by J. B. Lippincott Company.

is shown in the figure. Round the orchestra, in size rather more than a semicircle, the stone seats for the audience rose tier above tier like a large flight of steps. As the theatre was intended to accommodate practically the whole population of the city in which it stood, these rows of seats were of enormous size, the theatre of Dionysus at Athens holding nearly 30,000 persons, and that at Megalopolis being computed to seat 44,000. In order to obtain the necessary slope for the tiers of seats, the Greeks always chose some natural hollow, where the shape of the ground aided the design of the architect. Between the auditorium and the stage were the passages of entrance (*parodoi*), which, in the theatre at Segesta, seem to have been of unusual breadth.

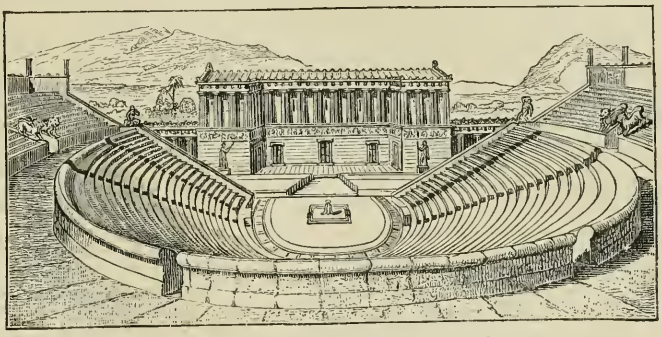

Fig. 1.—Theatre at Segesta, restored.

The stage (*logeion*) was a long, narrow platform, standing, according to the latest theories, about 12 feet higher than the orchestra, and was used by the actors, as distinguished from the chorus. It was bounded at the back and on each side by the wall of the buildings which contained the dressing-rooms of the actors and the other necessary apartments. The stage and back wall were called the *proskēnion*; the side walls, or wings, in each of which was an entrance door, being named *paraskēnia*. A flight of steps connected the stage with the orchestra, and these steps, continued out of sight, were the means by which apparitions from the lower world ascended. The wall of the dressing-rooms, &c., which formed the back wall of the stage, was ornamented with columns, and represented the front of a temple or other building, before which the action of the play was supposed to take place. It had three doors in it, by which entrances and exits were made. When the action of the play required a different scene, the back of the stage was covered with painted curtains or boards, which were practically never changed in the course of a play. At either end of the stage were the *periaktoi*, large, revolving triangular prisms, each side of which bore a different scene, thus providing, as it were, three set of wings. For machinery there was the *ekkyklēma*, a platform on which a tableau, depicting an incident which could not be shown on the stage, was rolled forward from one of the doors of the *proskēnion*, exhibited to the audience, and rolled back again. There was also the *mechane* (*machina*), by which a god could be lowered from heaven to earth, which was probably some sort of crane. From it we derive the phrase of a *Deus ex machinâ*. The curtain, which was not an invariable feature in a Greek theatre, rose from below, instead of falling from above as in modern times. In dealing with the early Greek theatre it must always be remembered that the stage was only of secondary importance, the orchestra being deemed the chief point of interest. The Romans, whose theatres were founded in most respects on Greek models, differed in this point. They transferred all the singing and dancing to the stage, and gave up the orchestra to the most important section of the audience. The most perfect existing specimens of the early Greek theatre are to be seen at Epidaurus, at Aspendus in Pamphylia, and at Athens, where the remains of the theatre of Dionysus, on the rising ground at the foot of the Acropolis, are most interesting and full of information. At Orange, in the south of France, there is a splendid specimen of an ancient Roman theatre.

During the middle ages, when the drama existed only in the form of mysteries and miracle-plays, and was under the management of the church, theatres were not required. Plays were represented generally in cathedrals or monasteries, and the most elaborate scenery ever used was a three-story scaffold to represent heaven, earth, and the nether world. But it would seem that at a very early period there were in England open-air theatres of some sort; for in Perran Round, near Perranzabuloe (q.v.) in Cornwall there exists what must have been a theatre of large extent, with raised seats all round, somewhat after the Greek fashion. With the revival of learning in the 16th century came also a revival of the drama, and theatres began to be built. The earliest was probably a play-house of some sort in the Hôtel de Bourgogne, Paris, which was built about 1548 for the Confraternity of the Passion; but the first regular theatre was that which Bramante constructed at Rome in the Grand Court of the Vatican about the year 1580. Then came the Teatro Olimpico at Vicenza, designed by Palladio, and finished in 1584; while the earliest theatre built on modern lines was constructed by Aleotti at Parma in 1618. In all the early Continental theatres the construction was founded on Greek models, but in England a simpler idea served. Here the earliest dramatic performances took place in booths, in tennis-courts, or in the open court-yards of inns; and it was not till the end of the 16th century that the first permanent building was erected for theatrical purposes. This was 'The Theatre,' built by Burbage in Shoreditch in 1576, which was founded, not on any classical model, but on the inn-yards in which the actors had been accustomed to play. The stage was literally a stage—a platform erected against one side of the building—and on three sides of this platform the spectators stood or sat in the pit (then called the *yard*), while all round it ran the galleries or boxes (then called *rooms*) exactly like the galleries of an inn-yard. There was no provision for scenery. The door at the back of the stage, which communicated with the dressing-rooms, &c., and was the general entrance for the actors, was hung with curtains, and there seem to have been 'traverses,' or curtains running on rods, some distance up the stage, which could be drawn and undrawn to indicate an inner apartment; but the locality in which the scene was laid was indicated only by a ticket stuck up bearing such an inscription as 'A Garden,' 'Thebes,' or 'Rhodes.' *Properties* were, however, largely used to give verisimilitude to the action. For instance, the first items of one of Henslowe's inventories include 'one rock, one cage, one tomb, one hell-mouth, one bedstead.' These properties seem to have been pushed on the stage in the calmest fashion. Thus, in Middleton's *Chaste Maid in Cheapside*, one of the stage-directions is, 'A bed is thrust out upon the stage, Alwit's wife in it;' and a similar action is

indicated in the stage-direction, 'Enter Anne in bed,' in Davenport's *New Trick to Cheat the Devil*. In the stage there were *traps* apparently to a considerable extent; while behind and on a higher level was a platform which did duty for any elevated part of the supposed scene. Thus, it would represent the walls of a city, a tower, or Juliet's balcony. Malone supposes that, in the play-scene in *Hamlet*, the king and courtiers sat on this raised platform, while the players occupied the regular stage, and acted with their backs turned towards the pit. It seems, however, quite as probable that the arrangement was exactly the reverse, the mimic play being acted on the platform. In the Elizabethan theatre the stage was strewed with rushes, or, upon very special occasions, was matted; and on it the gallants sat on stools, showing their dress and figure to the audience, and destroying, as it seems to us, anything resembling dramatic illusion. The only existing contemporary drawing of the

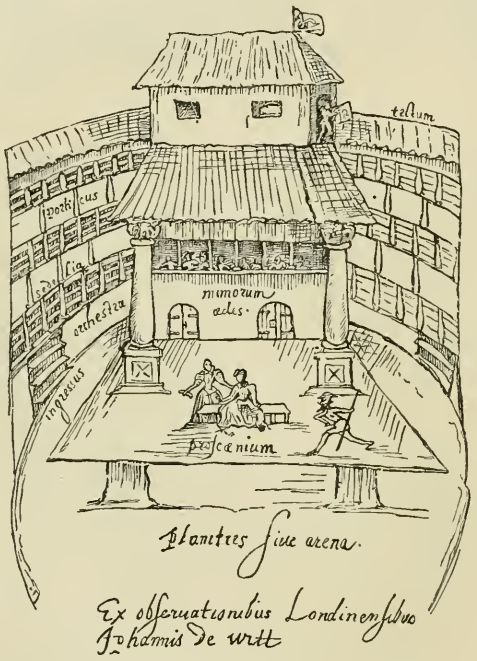

Fig. 2.—The Swan Theatre, London, in 1596.

Elizabethan stage is here reproduced (fig. 2). It is taken from Dr Gaedertz' book on the *Old English Stage* (Bremen, 1888), and represents the Swan Theatre in 1596. The drawing was made by one John de Witt, who visited London in 1596, and whose manuscript diary Dr Gaedertz discovered in the Royal Library at Berlin. As a picture of the stage in the time of Shakespeare it is of infinite value.

After the Restoration, under the supervision of Charles II., who was familiar with the French stage, the English theatre came more into line with the Continental. The stage was gradually withdrawn closer and closer to the proscenium opening, until, by the middle of the 18th century, the appearance of the interior of Drury Lane was not seriously different from that which it presents at this day. In the years immediately following the Restoration many important changes were made in the conditions of the English theatre, the two greatest being the introduction of elaborate scenery and the playing of female parts by women. Up to this time Juliet, Ophelia, and Desdemona had been acted by a beardless boy; while the older female characters were represented by full-grown men. Strange though it seems, great reputations were made by actors in both lines, notably by Edward Kynaston, as a boy-actress, and James Nokes, as an old woman. Movable scenery, which was invented by Baldassare Peruzzi early in the 16th century, had long been used in masques, but it was not till 1661 that it was used to illustrate a regular stage-play in England. It has steadily grown more and more elaborate—a new development of 'set-scenes' being made by Garrick's scene-painter, De Loutherbourg, in 1777—until it has threatened to overshadow the play; and indeed it has been gravely argued that with the introduction of scenery and spectacle began the decay of the drama.

The arrangements of the auditorium of a theatre have changed little during the last two centuries, the chief alteration being the curtailment of the space occupied by the pit. At the Restoration, and all through the 18th century, the whole floor of the house, from the back wall to the rail of the orchestra, was devoted to the pit; but about 1833 Alfred Bunn introduced stalls, which have gradually encroached farther and farther, until in very fashionable theatres the pit is restricted to a few benches far away under the dress-circle, or is abolished altogether, as is the case in opera-houses. In all theatres the floor, whether used for stalls or pit, or both, slopes considerably towards the stage. The various tiers of galleries do the same, except in those theatres where they are not seated with benches, but divided into private boxes. The orchestra, which is now generally located immediately in front of the pit or stalls, was in Shakespeare's time placed in a gallery above the stage. In some theatres the musicians are placed under the stage, whence they discourse muffled music.

In order to realise the modern arrangements behind the scenes, let us imagine ourselves on the stage of a large theatre. Entering by the stage door, we thread our way through narrow passages, blocked by pieces of scenery, until we find ourselves in the *wings*, as the spaces on each side of the stage are named, from the wings or narrow side-scenes which mask the entrances to the stage and continue the picture which the main scene presents. Going forward until we reach the wall which divides the stage from the auditorium, we find, close to the opening through which the stage is seen by the audience, and which is called the *proscenium opening*, the little corner where that important official, the *prompter*, sits. Close to his hand is an elaborate arrangement of bells for signalling to the various parts of the theatre the exact moment when the curtain is to rise, when the orchestra is to cease playing, when the scenes are to be changed, when the traps are to be worked. Beside him is also a brass plate, covered with handles, for lowering or heightening the gas in footlights or elsewhere. The prompter generally, though not invariably, sits on the left of the stage—i.e. the left facing the audience; for right and left are calculated from the actor's point of view, which is naturally the reverse of the spectator's. The side which the prompter occupies is always known as the *P.S.* or *prompt side*, and the other as the *O.P.* or *opposite prompt*. Passing now through one of the *entrances*, as the spaces between the side-scenes are named, we find ourselves on the stage, and realise that we stand, not on a level surface, but on an inclined plane, the slope of which is towards the audience. In front of the stage we see the *footlights*, sometimes also called the *floats*, a row of gas-jets, with strong reflectors, which supply the chief illumination of the actors' figures. For moonlight and other effects they are provided with

movable screens of coloured glass or coloured cloth, called *mediums*. Within the last few years electric lighting has supplanted gas in many theatres, and great expectations are entertained of the effects which may ultimately be obtained from the new mode of illumination. In 1892, at the Electrical Exhibition at the Crystal Palace, some very wonderful effects of the electric light as applied to the stage were shown. Turning our back on the footlights, if no scenery is set we see, away in the darkness at the back of the stage, the *scene-dock*, a large space for storing scenery when not in use. By clearing this dock a great addition can be made to the depth of the stage when spectacular plays demand it. Looking up above our heads we see rows of lights suspended, which are technically called *battens*, and beyond these a wilderness of canvas and ropes and pulleys. But the prompter rings his bell, and a great expanse of painted canvas, called a *cloth*, swings into sight from the regions above the stage; wings are pushed forward to conceal the edges of the cloth: and narrow slips of painted canvas are dropped to mask the top of it. These are called *borders*, and may represent a ceiling, the sky, branches of trees, or whatever is necessary to aid the illusion of the scene. In the modern theatre the cloth has supplanted in a great measure the old contrivance known as *a pair of flats*. These were two frames of stretched canvas, which were run on in *grooves* fixed over the top of the stage and met in the middle, forming two halves of a scene. So seldom are these used now that grooves are not often met with in new theatres, except the short grooves in which the wings run, which are technically known as *forks*. In all first-class theatres the scene generally used is a *set-scene*, which is built so solidly, and reproduces the conditions of nature with such completeness as scarcely to make any demands on the imaginative faculty of the spectators. If a room is represented, the walls and ceiling are built with marvellous solidity; a chandelier hangs from the centre of the ceiling; the doors shut with an unmistakable bang; the windows open and close better than they sometimes do in actual life. In elaborate spectacular plays whole pieces of scenery are raised through large transverse openings in the stage by means of platforms, which are termed *bridges*. These work in and out of the *well*, or *cellar*, a space under the stage nearly as deep as the proscenium opening is high. There is an intermediate floor running round the well, which is called the *mezzanine*. It is about 8 feet below the stage, and from it the *star trap* and the *vampire trap* are worked. These are contrivances for the sudden appearance or disappearance of demons in pantomime. In the vampire trap the actor throws himself against a couple of shutters in the stage, which open to let him through and immediately close again with great force, he landing on a mattress placed to catch him on the mezzanine. The star trap is cut in the stage like a star, with the points meeting in the centre. The actor stands on a little platform on the mezzanine, which is run up with tremendous force by counter weights against the stage. The actor's head opens the points of the star, through which he shoots like an arrow, and before he reaches the stage again the star has closed and is kept solid by the platform on which the actor came up. Farther 'up' the stage—i.e. nearer the back scene—is the *grave trap*, used, for instance, at Ophelia's funeral. These are the chief traps, but the whole stage of a theatre is practically movable, the only immovable parts being the narrow joists, which are called *runners* or *fillets*. Above the stage are the *flies*, large lateral galleries, in which the scene-men work their ropes and pulleys, and from which the lime-light which plays so important a part in the effects of a modern theatre is managed. Higher still is the *gridiron*, an open line of strong beams, from which the various cloths are suspended; and above it again is the *barrel-loft*, in which are placed the windlasses and drums by which the curtain and cloths are worked. At the very top of the theatre, and at the extreme back of the stage, is generally the *paint-room*, in which the scenic artist works. His canvas is stretched on a movable frame, which he drops or raises as he requires, and when a scene is finished it is lowered directly to the stage.

Among famous theatres are the Scala at Milan, the San Carlo at Naples, the opera-houses of St Petersburg, Vienna, and Berlin, and the Court Theatres of Munich and Dresden. Most notable of all architecturally is the Grand Opera-house in Paris, completed in 1875 at a cost, exclusive of site, of £1,120,000; and in Paris also is the most famous theatre in the world for its history and traditions, the Théâtre Français. At Bayreuth is the grand theatre constructed by Wagner to carry out his views on the dramatic art. It is a huge structure, practically all on one floor, with a slightly fan-shaped auditorium, perfectly adapted both for seeing and hearing. But it is practically defective in the important respect that it occupies an enormous space in proportion to the number it holds. The problem of the theatrical architect everywhere is now how to contain the greatest number in the smallest space. A curious expedient is that of a double stage, which is used in the Madison Square Theatre, New York. While an act is in progress the scene required for the succeeding act is set on the second stage, which is above the first; then the stage sinks, and the new scene is in its place ready for the next act.

The art of acting, as understood by the Greeks, had little in common with our present-day theories. The first qualification for the ancient actor, especially in tragedy, was voice, for by that chiefly could he affect his audience. He could get no effects from facial expression, for his features were concealed by a mask, which was of course immovable. He could not get sudden effects of terror or surprise by active motion and gesture, for he was hampered by a 'make-up' which must have been burdensome in the extreme. First, he wore the *cothurnus*. This tragedy-boot had an enormously thick sole, which raised the hero a considerable height above his fellows, and on which he must have 'clumped' about the stage in the ungainliest fashion. He had to walk with the greatest care to avoid stumbling, and, if he fell, apparently had to be lifted on his legs again in somewhat undignified fashion; an accident which, Lucian records, happened to Æschines when acting the part of Œnomaus. To increase his height still further his mask had a high top to it, called the *onkos;* and to prevent his looking lanky he was padded out to a suitable proportion to his height. His dress was almost the ordinary Greek costume, but of very brilliantly coloured material. The comic actors wore masks both in the old and the new comedy, but their costumes were probably less burdensome, although they appear to have been padded in ludicrous fashion. Thus Greek acting must have been in the last degree conventional and unnatural, differing therein very widely from the Roman, which appears to have been highly emotional. In England even up to the time of the Restoration acting must have been, like the Greek, more rhetorical than emotional. This is implied by the position of the stage, with spectators on three sides and an audience of gallants actually seated on it; but after 1660, as the stage gradually came nearer its present condition of a picture

framed by the proscenium, acting became more in accordance with our modern ideas of dramatic representation.

Licensing of Theatres.—Up to 1843 the only theatres entitled to act regular plays were those which held royal patents—in London, Drury Lane, Covent Garden, and the Haymarket (in summer)—but in that year Bulwer's Act (6 and 7 Vict. chap. 68) established practically free trade in theatricals. By it the Lord Chamberlain was made licensing authority in London and Westminster, Finsbury, Marylebone, Tower Hamlets, Lambeth, and Southwark. Outside his domains the power vested in the justices of the peace. By the Local Government Act, 1888, the authority of the justices was transferred to the county councils, wherever such existed; but in a very great majority of cases these took advantage of a clause in the act which authorised them to delegate back to the justices their licensing powers. In London at present the Lord Chamberlain licenses thirty-seven theatres, as against six licensed by the county council in parts of the metropolis outside his jurisdiction. The Select Committee on Theatres (see Report published in *Times*, 3d June 1892) recommends that the Chamberlain's jurisdiction should in future extend over all theatres in all parts of London.

The following are among the best-known actors in Italy, France, Germany, England, and America:

ITALY.

Modena.
Ristori, Adelaide (b. 1821).
Rossi (b. 1827).
Salvini (b. 1830).

FRANCE.

Molière (1622–73).
Poisson, Raymond (died 1690).
Champmêlé, Mdlle. (1644–98).
Baron (1653–1729).
Lecouvreur, Mdlle. (1690–1730).
Le Kain (1729–78).
Grandval (1710–84).
Préville (1721–99).
Clairon, Mdlle. (1723–1803).
Dumesnil, Mdlle. (1713–1803).
Monvel (1745–1812).
Talma (1763–1826).
Mars, Mdlle. (1778–1847).
Georges, Mdlle. (1787–1867).
Rachel, Mdlle. (1821–58).
Lemaitre (1798–1876).
Regnier (1807–85).
Got, François (b. 1822).
Delaunay, Louis (b. 1826).
Coquelin (b. 1841).
Bernhardt, Mdme. (b. 1844).

GERMANY.

Neuber (1692–1760).
Eckhof (1720–78).
Schönemann (1704–82).
Fleck (1757–1801).
Iffland (1759–1814).
Schröder (1744–1816).
Devrient, Ludwig (1784–1832).

GERMANY—*continued.*

Seydelmann (1793–1843).
Devrient, Emil (1803–72).
Dawison, Bogumil (1818–72)
Haase, Friedrich (b. 1827).
Wolter, Charlotte (b. 1834).
Barnay, Ludwig (b. 1842).

ENGLAND.

Burbage, Richard (*c.* 1567–1619).
Alleyn, Edward (1566–1626).
Taylor, Joseph (1585–1653).
Mohun, Michael (died about 1684).
Hart, Charles (d. 1683).
Betterton, Thomas (1635–1710).
Barry, Mrs Eliz. (1658–1713).
Pritchard, Mrs (1711–68).
Garrick, David (1717–79).
Jordan, Mrs (1762–1816).
Kemble, John P. (1757–1823).
Siddons, Mrs (1755–1831).
Kean, Edmund (1787–1833).
Macready, Wm. C. (1793–1873).
Faucit, Helen (Lady Martin, 1820–98).
Irving, Sir Henry (b. 1838).

AMERICA.

Cooper, Thos. A. (1776–1849).
Booth, Junius B. (1796–1852).
Duff, Mrs (1794–1857).
Burton, W. E. (1804–60).
Forrest, Edwin (1806–72).
Cushman, Charlotte (1816–76).
Jefferson, Joseph (b. 1829).
Booth, Edwin (1833–93).

See AMPHITHEATRE, ART, ATELLANÆ, BASQUES, DRAMA, FIRE (Vol. IV. p. 634), MASQUE, MIMES, MYSTERIES AND MIRACLE-PLAYS, OPERA, PANTOMIME; also J. W. Donaldson, *Theatre of the Grecks* (1849; new ed. 1875); Haigh, *Attic Theatre* (1889); J. Payne Collier, *History of English Dramatic Poetry, and Annals of the Stage* (1831; 2d ed. 1879. The statements in this work must be accepted with some degree of caution); Genest, *Account of the English Stage, 1660–1830* (Bath, 1832); Doran, *Their Majesties' Servants* (1864; 3d ed. 1888); Ward, *History of English Dramatic Literature* (1875); Fleay, *Chronicle History of the English Stage, 1559–1642* (1890); Hawkins, *Annals of the French Stage to the Death of Racine* (1884), and *French Stage of the Eighteenth Century* (1888); Parfaict, *Histoire du Théâtre François* (1745–49); Lucas, *Histoire Philosophique et Littéraire du Théâtre Français* (1847–63); Devrient, *Geschichte der Deutschen Schauspielkunst* (1848–61); Dunlap, *History of the American Theatre* (1833); George P. Seilhamer, *History of the American Stage before and after the Revolution* (3 vols. 1888–91). Full lists of works relating to the English, Scotch, and Irish theatres will be found in the present writer's *Bibliographical Account of English Theatrical Literature* (1888).

Théâtre Français, or COMÉDIE FRANÇAISE, the theatre in the Palais Royal, Paris, in which the classical drama of France receives its most perfect and artistic representation, dates from 1680, when Louis XIV. combined the actors of the Hotel Bourgogne and Molière's company, and gave them a special organisation and a yearly subvention of 12,000 francs. In 1770 the theatre was established in the Tuileries, in 1782 was removed to a new building where the Odéon now is, and after the troublous times of the revolution was finally established in the Palais Royal. The present constitution dates from 1803. The committee of six, presided over by government officials, names the *sociétaires* (the actors and actresses who belong to the staff) and the less permanent *pensionnaires*, superintends all financial arrangements, makes a point of reproducing from time to time the really great French plays, and sits in judgment on new plays submitted. The subvention is now 240,000 francs. The *Théâtre Français* is remarkable for perfect study, artistic dignity, and harmonious *ensemble*. Its bicentenary was celebrated with great éclat in 1880. There are histories by Lucas (2d ed. 1863), Chabrol (1884), and Despois (1886).

Thebaine. See OPIUM, Vol. VII. p. 613.

Thebes, the name of a celebrated Egyptian city, formerly the capital of Southern or Upper Egypt; called by the Egyptians Tuabu, by the Hebrews No-Amon, by the Greeks Thebæ, and at a later period Diospolis Magna. It lies in the broadest section of the valley of the Nile, in about 26° N. lat., at a spot where the desert on the west sheers away to the girdling range of the Libyan mountains, leaving a broad plain, partly cultivated, on which stand the famous twin statues, one of which is known as the 'vocal Memnon' (q.v.), and behind them the temples grouped about the modern districts of Kurna and Medînet-Habû. The Nile divides this western part or Necropolis of Thebes, anciently called the 'Libyan suburb,' from the extensive ruins now known by the names of the villages Luxor (el-Uksur, 'the palaces') and Karnak which stand on the eastern bank, with the low range of the Arabian hills for a background. The traditional foundation of Thebes goes back to the 1st dynasty, but no buildings have hitherto been found earlier than some slight constructions of the 11th dynasty, 2500 B.C., who appear to have founded the original temple of Amen-Ra, the special god of the city. Its most flourishing period was under the 18th, 19th, and 20th dynasties, or from about 1600 to 1100, when it had supplanted Memphis, the ancient capital of the Pharaohs. The central situation of Thebes secured it from the attacks of the northern enemies of Egypt, and contributed to its prosperity; and here the worship of Amen-Ra arose in all its splendour; magnificent palaces and temples were built in its different quarters by the great monarchs of the Theban dynasties, and were added to by later kings, down to the time of the Ptolemies and Antonines, to the 2d century A.D. It was enriched by the spoils of Asia and the tributes of Ethiopia, and its fame and reputation had reached the early Greeks. Homer describes it by the epithet of Hundred-gated (ἑκατομπύλαι Θῆβαι), doubtless in allusion to the gates or pylons of its temples, for Thebes was never a walled or fortified city. In the plenitude of its power it sent forth an army of 20,000 war-chariots; but about 1100 B.C. the Bubastite and Tanite dynasties removed the capital again to the north, to Sais and Memphis,

and thenceforth Thebes declined in importance. At the Persian conquest in the 6th century B.C. Cambyses obtained a spoil of nearly £2,000,000 from the city, and destroyed many of its noblest monuments. The foundation of Alexandria still further injured it; and at the time of Strabo Thebes was only a cluster of small villages. Its temples, tombs, and ruins were frequently visited by Greek and Roman travellers, including the Emperor Hadrian. At a later period a considerable Christian population lived there under the empire; but at the Arab invasion the inhabitants fled to Esné. Thebes is now inhabited only by Fellahîn, by a few officials, and by the migratory visitors to the three hotels at Luxor.

Of the monuments on the west or Libyan side the principal are the three temples of Seti I. and Rameses II. and III., known respectively as El-Kurna, the Rameseum (or Memnonium), and Medînet-Habû. Close to the Rameseum is the fallen and broken colossus of the founder, the largest statue in Egypt, originally nearly 60 feet high, celebrated in Shelley's sonnet as that of Osymandyas, whose palace the temple was believed to represent. Near by are also some remains of two temples of Amenoph III., whose two colossal statues still survey the green fields in front. Some way behind the Rameseum, on a spur of the hills, is the terraced temple of Queen Hatasu (18th dynasty), known as Deyr-el-Bahri, near which a remarkable series of thirty-nine royal and priestly mummies, papyri, &c. were found by Emil Brugsch in 1881. At Medînet-Habû is a pile of buildings, of which the chief is the great temple of Rameses III. (the Rhampsinitus of Herodotus), with sculptures representing his victories over the Philistines, the life in his harem, the riches of his treasury, and a calendar with inscriptions dated in the twelfth year of his reign. Near here, to the north-west, are the cemeteries of the sacred apes, and further on the valley of the Tombs of the Queens, consisting of seventeen sepulchres, supposed to be the tombs of the Pallacides of Amen, mentioned by Diodorus and Strabo. Near them, among the hills, are the Bibân-el-Mulûk, or Tombs of the Kings of the 19th and 20th dynasties, sixteen in number, the most interesting of which are those of Seti I., called Belzoni's, after its discoverer, and of Rameses III., named by Bruce the 'Harper's tomb.'

On the east bank the chief monuments are at Luxor, the beautiful temple of Amenoph III. (18th dynasty), added to by Rameses II., with its well-known obelisk, the fellow of which was removed to the Place de la Concorde at Paris; and the still more magnificent temple, or rather group of temples, at Karnak, the sanctuary of which, built by Osirtasen I. of the 12th dynasty, was added to by the monarchs of the 18th. The most remarkable part of this wonderful mass of pylons, courts, and obelisks is the great hall, 170 feet by 329 feet, built by Seti I. and Rameses II., with its central avenue of twelve massive columns, 62 feet high and 12 feet in diameter, and its 122 other columns, and two obelisks (originally four), one of which is the tallest in Egypt, 108 feet high. On the walls the sculptures tell the glorious history of those two warrior kings, how they fought against the Hittites and the Ruten, and the Arabs and the Syrians, and the people of Armenia, and took from them their strong cities. Here, too, is the so-called Portico of the Bubastites, built by Shishak I., recording his expedition against Jerusalem, 971 B.C.

The Thebaid, the territory of Thebes, was a term applied to various areas at various times, but generally to one of the three main divisions of Egypt. It is specially familiar to us as being a favourite place of retreat for Christian hermits.

Thebes, the principal city of Bœotia in ancient Greece, situated on the slopes of Mount Teumessus, and between two streams, the Dirce and the Ismenus, about 44 miles to the north-west of Athens. Its acropolis continued to be called Cadmeia from the legend that it was founded by a colony of Phœnicians under Cadmus. Here were born Dionysus and Hercules, Tiresias and Amphion; this was the scene of the dark tragedy of Œdipus, the war of the Seven against Thebes (see ADRASTUS), the terrible vengeance of the Epigoni. But the story of the city enters the world of history in the dispute between Thebes and another Bœotian city, Platæa, which involved the former in an unsuccessful war with Athens, and began that bitter enmity that never died out till the death of Greek liberty itself. During the Persian war Thebes sided with the Asiatic invader, but Sparta, jealous of Athens, interfered to prevent the unworthy city being deprived of her supremacy over the other Bœotian cities. When the Peloponnesian war broke out Thebes took part with Sparta, and at its close was eager for the destruction of Athens; but it soon began to dread the overgrown power of its ally, and sheltered the Athenian exiles from the rule of the Thirty Tyrants. Hence arose a bitter antagonism between Thebes and Sparta, and a varying struggle, which closed with a short period of Theban supremacy over all Greece, won by the glorious victory of Epaminondas at Leuctra (371), but ended by the hero's death in the moment of victory at Mantinea (362). The eloquence of Demosthenes induced Thebes to unite in opposition to the encroachments of Philip of Macedon; but it was too late, and in 338 B.C. the battle of Chæronea crushed the liberties of Greece. After Philip's death the Thebans made a fierce but unsuccessful effort to regain their freedom, but their city was taken by Alexander, levelled to the ground, and the entire population sold into slavery (336). In 316 it was rebuilt by Cassander (whose walls were traced by E. Fabricius in 1888); and it was taken by Demetrius Poliorcetes in 290. It was plundered by Sulla, and in Strabo's time was a miserable village. During the 11th and 12th centuries it revived through its silk manufacture, but under the Turks again declined, though its modern representative, Thiva, has still a population of about 4000. See E. Fabricius, *Theben* (1891).

Thecla, a virgin saint of the early church, a member of a noble family of Iconium in Lycaonia, where she was converted by the preaching of St Paul, and, having devoted herself to a life of virginity, suffered a series of persecutions from her intended bridegroom, as well as from her parents. She is said to have died at the age of ninety in Seleucia. The apocryphal *Acts of Paul and Thecla* were edited by Tischendorf in the *Acta Apostolorum Apocrypha* (Leip. 1851). See Lipsius on the Apocryphal Acts (Brunswick, 1886), or the monograph by Schlau (Leip. 1877).

Theed, WILLIAM (1804–91), sculptor (son of William Theed, R.A., sculptor, 1764–1817), is known by the statues of Newton at Grantham, Lord Derby at Liverpool, Peel at Huddersfield, and the Africa group on the Albert Memorial.

Theft is the unlawful taking away of another man's property. To constitute the crime three things are necessary—the *animus furandi*, or intent to steal, the *asportavit*, that is, the goods must be removed from the owner's possession, and this must be done *domino invito*, against his will. The thing stolen need not be in the possession of the owner; thus, if a man finds lost property, and, knowing to whom it belongs, converts it to his own

use, he is guilty of the offence. Again, if a man receives an article for a special and temporary purpose and appropriates it he commits theft. A guest at an inn making off with the vessels or plate brought to him during a meal is an example. Again, the owner may be induced to part with the property by a false pretence; this would be theft according as he did not or did intend to transfer the right to the goods. Thus, if A got from B a horse on the pretext that he wished to show it to a possible customer, A would be guilty of theft if he kept the animal; but if he obtained possession by representing that he wanted it for himself and would pay for it next day, a payment he could not and did not intend to make, he would be guilty of obtaining goods by false pretences. Both parties may in the first instance be deceived or mistaken, but the subsequent conduct of one may make him a thief. Thus, A agreed to lend B a shilling; the coin that passed was a sovereign. B finding this out later kept it; after some doubt he was found guilty of theft. If an article is pledged it is theft if either of the two parties to the contract take possession of it to the detriment of the other; so the partner of a firm or the member of a corporation may steal the partnership or corporation property, but a married woman living with her husband does not commit theft when she converts his property to her own use. If the theft be from the person, and accompanied by violence or threats, it is robbery; if committed by a clerk or servant, upon property received by him on account of his master, it is embezzlement. To buy or accept, knowingly, stolen goods is not theft, but receiving—a crime punishable with fourteen years' penal servitude or less, according to the nature of the theft. The following cannot be stolen: Land and things permanently attached thereto, or documents relating to the title thereof; running or standing water not stored for use (gas and electricity may be stolen); animals running wild, corpses, and things abandoned by their owners. Child-stealing, viz. the abduction of children under the age of puberty, is an offence, but as committed against the person is not properly theft. In England formerly theft was either *grand* or *petit* larceny. The latter was restricted to the taking of property to the value of one shilling or less. If the value was greater it was the former, and was punishable between the time of Edward I. and 1827 with death. Very severe sentences may still be inflicted for various kinds of theft. Thus, to steal a will or a letter in the custody of the post-office is punishable with penal servitude for life.

See Stephen's *Digest*, *General View*, and *History of the Criminal Law*. See also STOLEN GOODS.

Theine. See TEA.

Theism (Gr. *theos*, 'God'), etymologically equivalent to belief in a god or gods, and as such opposed to Atheism (q.v.), is now usually understood to mean the doctrine of the One, supreme, personal God, 'in whom we live, and move, and have our being'—as distinguished from Polytheism (q.v.), which recognises more gods than one; from Pantheism (q.v.), which denies the divine personality; from Agnosticism (q.v.), which denies that we can know anything of God; and from Deism (q.v.), which, etymologically equivalent to Theism, is generally defined as recognising the personality of God, but denying His providence and active presence in the life of the world (though it should be remembered that many deists would not have admitted that this was their doctrine). Deism further explicitly rejects revelation and trinitarian conceptions of the godhead, while Theism may or may not accept these doctrines. But the term theism was often used as equivalent to deism with its negative postulates: and when Theodore Parker speaks of 'Theism,' or when the Brahmo-Somaj is called the 'Theistic Church of India,' or a book is published with such a title as *Theistic Devotions*, that kind of theism is also meant which either denies or at least does not include Trinity, incarnation, inspired and infallible revelation, or miracle.

Various views of the origin of the notion of God, and the relation of the monotheistic religions to nature-worship, animism, spiritism, and polytheism, have been indicated in the article Religion (q.v.); together with several definitions of religion as man's attitude towards God.

Theism as the doctrine of the nature and attributes of God covers a large part of the field of theology and speculative philosophy. But in practice it is usually restricted to the maintenance of the thesis that God may be known; the history of the origin and development of the idea of God; and the statement, criticism, and defence of the arguments for the existence of God. The main part of its work is apologetic, in opposition to the hostile systems and theories, rather than a scheme of systematic Theology (q.v.). No competent apologist now stakes the existence of God on any one argument, or exhibits the proof as a series of syllogisms. It is rather maintained that the study of human history, of human nature especially on its moral and spiritual side, and of the world as far as science reveals it to us make for the existence of a God, demand such a postulate as the key to the universe, and render the belief in a personal God greatly more probable than any other thesis—a subject vastly too wide for discussion here. But it is necessary to name what are often referred to as the four great arguments for the existence of God. (1) The *ontological* argument first formulated by St Anselm proceeds from the notion of a most perfect being to infer his existence; without actual existence the idea would fall short of perfection. The argument was re-stated in a different shape by Descartes (q.v.) and by Samuel Clarke, and, though very contemptuously treated by Kant, is still an element of the argument that without a God the world is a chaos.

(2) The *cosmological* argument, employed by Aristotle, Aquinas, and a host of Christian authors, is an application of the principle of Causality (q.v.). We cannot conceive an infinite regression of finite causes; therefore beyond the last or first of the finite causes is the Infinite. From motion the argument is to a mover.

(3) The *teleological* argument, or argument from design, proceeds from the order and arrangement of the universe, the reign of law and beauty and adaptation, to the intelligent and supreme fountain of order. This is the most familiar of the arguments, especially on the lines laid down by Paley.

(4) The *moral* argument was that relied on by Kant (q.v.) when he destructively criticised the other three, and forms a part of most modern theistic arguments. God is a postulate of our moral nature; and the moral law in us implies a lawgiver without us.

See, besides general works on apologetics and dogmatic theology, Professor Flint's *Theism* (1877; 4th ed. revised, 1889); Harris, *The Philosophical Basis of Theism* (New York, 1883); *The Grounds of Theistic and Christian Belief* (New York, 1883); the Duke of Argyll, *The Reign of Law* (1866; 19th ed. 1890); Kant's *Critique of Pure Reason*; Mill's *Three Essays*; Janet's *Final Causes* (trans. 1878); and the Gifford Lectures (1888 *et seq.*).

Theiss (Hun. *Tisza*), an important affluent of the Danube, and the chief river of Hungary, rises by two streams, the Black Theiss and the White Theiss, in the Carpathian Mountains. It winds 750 miles north-west, south-west, and finally southward, joining the Danube after running parallel to

it for 300 miles. The Theiss has several large and navigable affluents, as the Maros and Bodrog. The lower part of its course is sluggish, and it has often inundated the plains, flooding the cities on its banks, such as Szegedin (q.v.). Much has lately been done to regulate the course and drain the marshes on its banks. The Theiss is extraordinarily rich in fish.

Thellusson, PETER, the son of Isaac de Thellusson, ambassador of Geneva at the court of Louis XV., was born in Paris, 27th June 1737, and settling in London as a merchant in 1762, acquired enormous wealth, which at his death (27th July 1797) he disposed of by a will that led to a special act of parliament and much litigation. After bequeathing large fortunes to all the members of his family, he left the residue of his wealth (estates worth £4500 a year and personal property to the amount of £600,000) to trustees, to accumulate during the lives of his three sons and of all their sons. The accumulated fund (estimated to be likely to produce some £19,000,000) was then to be used to purchase estates for the eldest lineal descendant of his three sons. The will was contested by the heirs at law, but affirmed in the House of Lords in 1805; though meanwhile the Thellusson Act (see PERPETUITY) had been passed (1800), restraining testators from devising their property for accumulation for more than twenty-one years. Thellusson's last grandson died in February 1856; and there was then a lawsuit as to whether the property should go to the eldest male descendant of Thellusson or to the eldest male descendant of Thellusson's eldest son. To the latter (Lord Rendlesham) it was finally adjudged on appeal to the House of Lords (9th June 1859); but, by reason of the large expenses, the total sum inherited was said not much to exceed the sums bequeathed by the testator.

Thelwall, JOHN (1764–1834), tailor's apprentice, law student, man of letters, and radical. See Life by his widow (1837).

Themis, in Greek Mythology, one of the Titanides, the daughter of Uranus and Gē, was after Metis married to Zeus, and bore him the Horæ—Eunomia ('Equity'), Dikē ('Justice'), and Eirēnē ('Peace'); also the Moirai or Fates. She was regarded as the personification of order and justice, or of whatever is established by use and wont; and as such was charged by Zeus to convoke the gods, and preside over them when assembled, being likewise represented as reigning in the assemblies of men. In art Themis holds a cornucopia and a pair of scales. See Ahrens, *Ueber die Göttin Themis* (Han. 1862–64).

Themistocles, the great Athenian general and statesman, was born about 520 B.C. His father, Neocles, belonged to an undistinguished family of the middle class; his mother was a Carian. Ambitions from his cradle, he used his archonship of 493 for the promotion of his political plans. He saw what was best for Athens when he turned the attention of his countrymen to the sea and convinced them that a powerful fleet was absolutely necessary for their welfare. A large sum of money, the produce of the silver-mines of Laurium, which it was proposed to divide among the people, was devoted to its construction. During the war with Persia which followed Themistocles, commander of the Athenian squadron, which numbered 200 of the 324 vessels engaged, to avoid dissension was content to serve under the Spartan Eurybiadas, a man of narrow mind and hopeless obstinacy. On the eve of Salamis it required all the influence of Themistocles' vehement personality and threats to induce his timid superior and colleagues to await the attack of the enemy. In his eagerness to precipitate a collision, he sent by night a messenger to urge the Persian generals to make an immediate attack, as the Greeks had resolved on retreat. He thus provided for himself, whatever the issue might be. Intimation of the Persian advance was brought at nightfall by his rival Aristides, who had been ostracised in 483 B.C. The Peloponnesians refused to continue the pursuit of the Persians beyond Andros. From that place Themistocles sent a second message to Xerxes urging him to hasten back before the Greeks carried out their project of breaking down the bridges. Though later Themistocles may have found it convenient to interpret this act differently, it was honestly sent at the time with the intention of inducing Xerxes to leave Attica. The victor of Salamis was now the foremost name in the minds and mouths of men. The rebuilding of the walls of Athens by his advice on a scale far larger than anything in existence aroused great uneasiness among the allies of Sparta, but, by a series of adroit stratagems, Themistocles succeeded in cajoling the ephors till the walls had reached a height sufficient for defence. But his popularity was now waning, and the Spartan faction in Athens was plotting his ruin. Plutarch tells us that he provoked the anger and resentment of the citizens by his insufferable arrogance. In 471 B.C. ostracism was demanded, and he was banished from Athens. Argos was his first retreat, but so long as he remained there Sparta could have no security or peace. His condemnation on the false charge of implication in the treason of Pausanias drove him from Argos. He fled to Corcyra, and after a series of hairbreadth escapes was compelled to seek shelter in Asia. Artaxerxes received his suppliant with the greatest favour, and listened with attention to his schemes for the subjugation of Greece. It is said that the young king was so affected with joy that he was heard at night to cry thrice in his dreams, 'Themistocles the Athenian is mine.' After the Persian fashion, the town of Lampsacus was appointed to supply him with wine, Magnesia with bread, and Myus with other provisions. At Magnesia he lived securely till about 453 B.C.

'In a word,' says Thucydides, 'Themistocles, by natural force of mind and with the least preparation, was of all men the best able to extemporise the right thing to be done.' Of his moral character the great historian says nothing. But if his patriotism seems at times to have been but a larger kind of selfishness, it must be remembered that Themistocles was possessed of the conviction that no one could realise the dream of a great Athenian empire but himself. The sentence passed upon him was a bitter return for the unparalleled services he had rendered his country, and, due as it was to Spartan influence and jealousy, proved all the harder for a man of spirit to bear.

Theobald, LEWIS, an early Shakespearian critic, was born about 1688, the son of an attorney at Sittingbourne in Kent, and was bred to his father's business, but early took to literature, publishing in 1714 a tragedy entitled *Electra*, followed by twenty equally forgotten dramas. He published thirty papers under the name of 'Censor' in *Mist's Journal* (1715), and eighteen months later commenced the *Censor* as a separate tri-weekly paper, which extended to sixty-six more numbers. In 1726 he published his pamphlet, *Shakspere Restored, or a Specimen of the many Errors committed as well as unamended by Mr Pope in his late edition of this poet*, which the poet repaid by immortalising him as the original hero of the *Dunciad*. Theobald could not compete with his adversary in wit, but he proved himself a much more competent editor of Shakespeare by his edition in 1733 (7 vols.), which quite extinguished

that of his rival. He died in September 1744. Theobald was often very happy in his suggested emendations, and had the crowning merit of having much higher respect for his text than many much more brilliant men.

Theobalds, in Hertfordshire, near Waltham Cross, 13 miles N. of London, a former mansion built by Lord Burghley, who here often entertained Elizabeth. Exchanged for Hatfield (q.v.) in 1607 by his son the Earl of Salisbury with James I., whose favourite residence it was, and who died here, it was demolished in 1650 and 1762. The present Theobalds Park, on the other side of the New River, is an 18th-century mansion, the seat of the Meux family. Here Temple Bar (q.v.) has been re-erected.

Theobromine. See COCOA.

Theocracy, literally, 'government by God,' is the name given to that constitution of a state in which the Almighty is regarded as the sole sovereign, and the laws of the realm as divine commands rather than human ordinances. Under such a view the priesthood necessarily become the promulgators and interpreters of the 'divine commands,' and act as the officers of the invisible Ruler. The typical example of a theocracy is that established by Moses among the Hebrews.

Theocritus, the pastoral poet of Greece, was born early in the 3d century B.C. in Syracuse. The dates of his birth and death are not known, and we know but little of his life. He was educated at Cos under Philetas, a poet then famous, of whom Theocritus speaks with high respect (Id. 7). Cos then possessed a school of medicine, and Theocritus repeatedly mentions friends of his own, Nicias and Philinus, who were physicians, and whom probably he first met during their student days. Probably here also his friendship with the poet Aratus was formed. It is certain that a number of Theocritus' poems were composed between the years 270 and 250 B.C. He lived for a long time at the court of Ptolemy Philadelphus in Alexandria, where he wrote several of his idylls. In his pastoral poems Theocritus struck out an entirely new form of literature, which lives and is fresh for ever. Many of the poems which Suidas attributes to him are lost, and those which we have appear to be a selection from his writings. There is some question as to the authenticity of the thirty poems which we have. They show great differences of style, but this is quite consistent with the versatility of his genius. We do not question that dramas so widely different as *Prometheus Bound* and *Agamemnon* were written by one poet. His poems fall under three classes—half-epic, mimic, and idyllic. Probably the half-epic poems were the earliest written. The form of poetry most popular in Theocritus' day was the epic, as the *Alexandra* of Lycophron and the *Argonautica* of Apollonius Rhodius, both contemporaries of his, survive to show us, and during his youth Theocritus was most likely to be influenced by the tendency of the time. He has written a series of poems dealing with heroic legend, the infant Hercules, Hercules at the stables of Augeas, his encounter with the Nemean lion, and the episode of the Argonautic expedition when Hercules lost his young squire Hylas. In another very characteristic poem he describes the fight between the Greek hero, Polydeuces (a kinsman of Hercules), and the barbarian giant who is defeated in boxing, and made to promise to respect the rites of hospitality for the future; the combat is described with the utmost spirit. These poems are full of the spirit of Greek chivalry, and show Theocritus to be a Hellene at heart. Possibly he may have contemplated an epic poem on the exploits of Hercules, the great Dorian hero, and these poems may be fragments of it. Some of the poems, such as the 2d, 14th, 15th, and 21st, are dramatic scenes, and have been called mimic because they closely resemble in form the mimes of the Syracusan poet Sophron (Plato's favourite author), who wrote with great dramatic power dialogues probably in rhythmical prose, with male and female characters. Theocritus' famous 15th Idyll, *The Ladies of Syracuse*, is said to be copied from Sophron. It describes the visit of a Syracusan lady and her friend, both living in Alexandria, to the festival of Adonis. Nothing could be more natural than this poem. Lang says truly, 'the chatter of the women has changed no more in 2000 years than the song of birds.'

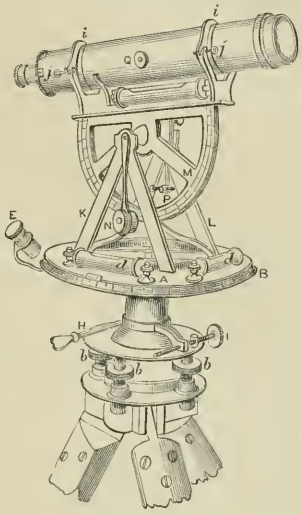
The Doric settlers in Sicily delighted in poetry resembling the ballads, love-songs, and dirges, and the improvised poems in answering couplets which are still sung in Sicily and in Southern Italy. Theocritus raised this rude pastoral poetry into a new and perfect form of literature. His short poems dealing with pastoral subjects, and, like paintings, representing a single scene, came to be called Idylls (*eidullia*) or 'little pictures,' a name probably not used by Theocritus himself. It is possible that the reaction between experience of country life on the Sicilian coast or on the slopes of Etna, and of life in a great and refined Greek city like Syracuse, and later in an enormous metropolis like Alexandria, was necessary to produce such poetry. Theocritus writes of the country because he loves it. His countrymen are not mere lay-figures dressed up with crook in hand. They are genuine country-folks, and show that combination of simplicity and love of nature with shrewdness in making a bargain which is found in the peasant everywhere. Every touch in these poems is natural and lifelike. After reading Theocritus the *Eclogues* of Virgil strike us as artificial. Take for instance the *Journey to the Feast*, which tells how the poet and two friends took their way from Syracuse to join a harvest-home party. On the road they overtake Lycidas, a goat-herd. To beguile the way Lycidas and Theocritus recite short poems of their own composition. Keats has written nothing more luscious than the description of the orchard-nook where the feast is held, which concludes the poem: verses which exhale the very mellowness and scent of summer. 'All things breathed the rich scent of summer, the scent of the time of ripe fruits.' Take again the poem of *The Fishers*—two old fishermen in their poor wattled cabin, filled with the implements of their craft, wake at midnight, and one of them tells how he dreamed that he caught a golden fish, and swore never to tempt the sea again; a poem which, in its sympathy with poverty and the toilers of the sea, is worthy of the author of *Les Misérables*. Strange power is shown in the idyll on the love of Polyphemus the Cyclops for Galatea. Nothing could seem further from love than the Cyclops, yet Theocritus makes us feel for the monster and pity him in the humility of his love and his hopeless passion. Hardly anywhere is there truer pathos than this poem contains. One of Theocritus' greatest charms is his power of landscape-painting. His landscapes bask in full sunlight. Kingsley says truly, 'Theocritus floods the whole scene with the gorgeous Sicilian air like one of Titian's pictures.' When Theocritus lived, Greek national life had ceased to be; imperial Athens was no longer; Greek religion had lost its vitality. No poet of Pericles' day could have written the fulsome eulogy on Ptolemy's repulsive marriage in the 17th Idyll. Had Theocritus lived in the age of Pericles, no doubt a stronger and more bracing air would have blown through his Arcadia, which remains for us a country good to

wander in, a sunny realm where men labour without care, and where life is undisturbed by anxious questionings. Dealing with pastoral life, Theocritus comes most into comparison with Robert Burns, who has far more depth, humour, and passion, but is without Theocritus' sense of beauty. Compared with the Scottish poet, Theocritus stands out at once as the man not only of genius but also of highest culture, accustomed to refined city ways, while the *comparative* roughness of Burns shows him as the man born and bred from earliest years in the 'pastoral world far from city and mart.' The power of Theocritus is seen in his influence over other poets. Virgil imitates him closely in his *Eclogues*. Tennyson has been deeply influenced by him: poems like *Œnone* and the idylls of country life remind us both in form and spirit of the Greek poet.

There are editions by Valckenaer (1810), Wüstemann (1830), Meineke (1856), Wordsworth (2d ed. 1877); two editions by Fritzsche, the larger with Latin notes (Leip. 1865–69), another with German notes and glossary (reprinted 1857); translations in verse by Chapman (1866) and Calverley (1869). Idylls 7 and 11 are exquisitely translated by Leigh Hunt (*Jar of Honey*). Prose translation by A. Lang (1889), with introduction.

Theodicy (Gr. *theos*, 'God,' and *dikē*, 'justice'), a name given to the exposition of the theory of Divine Providence, with a view especially to the vindication of the attributes, and particularly of the sanctity and justice of God in establishing the present order of things, in which evil, moral as well as physical, so largely appears to prevail. The name is of modern origin, dating from the close of the 17th century, or the beginning of the 18th century; but the theory, as well as the mysterious problem which it is meant to resolve, is as old as philosophy itself (see EVIL). The first to consider the question in its integrity was the celebrated Leibnitz (q.v.); and see OPTIMISM.

Theodolite, an instrument much employed in land-surveying for the measurement of angles horizontal and vertical, is neither more nor less than an altitude and azimuth instrument, proportioned and constructed so as to be conveniently portable. As in all instruments in very general use, the variations in its construction are almost numberless; but its main characteristics continue unaltered in all forms. It consists essentially of two concentric circular plates of copper, brass, or other material (the upper plate, or *upper horizontal*, either being smaller, and let into the lower, or *lower horizontal*, or the rim of the lower raised round the outside of the upper), moving round a common axis, which, being double, admits of one plate moving independently of the other. Upon the upper horizontal rise two supports, bearing a cross bar, which is the axis of a *vertical circle* moving in a plane at right angles to the former. This latter circle either has a telescope fixed concentric with itself, or a semicircle is substituted for the circle, and the telescope is laid above and parallel to its diameter. The circles, as their names denote, are employed in the measurement of horizontal and vertical angles. For these purposes the outer of the horizontal circles is graduated, and the inner carries the index-point and the Verniers (q.v.); the vertical circle is also graduated, and the graduations are generally read off by an index-point and vernier firmly attached to the supports. The upper horizontal is furnished with two levels placed at right angles to each other, for purposes of adjustment, and has a compass-box let into it at its centre. The stand consists of a circular plate supported on three legs, and connected with the lower horizontal by means of a ball-and-socket joint; the horizontal adjustment of the instrument being effected by means of three or four (the latter number is the better) upright screws placed at equal distances between the plates. The telescope is so fixed as to be reversible, and the adjustments are in great part similar to those of other telescopic instruments, but are too numerous and minute to be here detailed. Both horizontal plates being made, by means of the screws and levels, truly level, the telescope is pointed at one object, and the horizontal angles read off; it is then turned to another object, and the readings off from the graduated circle again performed; and by the difference of the readings, the angular horizontal deviation is given; and when vertical angles are required, the readings are taken from the vertical circle in a similar manner. For the much-disputed etymology, see *Notes and Queries* for 1884, &c.



Theodolite:
A, B, the horizontal limbs; *d*, *d*, spirit levels; E, a magnifier to read off the degrees; *b*, *b*, *b*, milled screws to adjust the instrument, and set in level; H, a clamping screw; I, a slow-motion screw, by which the instrument is moved more exactly than could be done by the hand; *i*, *i*, clips, to reverse the telescope by screws, *j*, *j*; K, L, frames into which the pivots are placed, on which the vertical arc, M, is turned round, and on which the telescope is fixed; N, a microscope for reading off the degrees; P, a slow-motion screw, by which the vertical arc and telescope are moved; Q, a milled screw for moving the object-glass of the telescope.

Theodora, the famous consort of the Byzantine emperor Justinian I., was, according to the dubious evidence of Procopius, the daughter of Acacius, a bear-ward at Constantinople, and had already been by turns actress, dancer, and shameless harlot, when she won the heart of the austere and ambitious Justinian, to become in succession his mistress, his wife, and the sharer of his throne (527). There was a law which forbade a member of the senate to marry an actress, but Justinian cleared the way by repealing it. Theodora was of less than middle height, and her complexion was pale, but such was her beauty that Procopius tells us 'it was impossible for mere man to describe her comeliness in words, or imitate it in art.' Never thereafter did the breath of scandal touch her name; she became Justinian's trustiest counsellor, bore a chief share in the work of government, and saved the throne by her high courage at the crisis of the Nika riots (532). 'Now every man must die once,' said she in council, 'and for a king death is better than dethronement and exile. . . . If you wish, O emperor, to save your life, nothing is easier: there are your ships and the sea. But I agree with the old saying that "empire is the best winding-sheet."' She lavished her bounty on the poor, and especially upon the unfortunate of her own sex, and died at forty (548), her slender and graceful frame worn out by the anxieties of state. Her character descended to history unspotted until the appearance (1623) of the *Secret History* of Procopius, the work of a man who had enjoyed the full favour and confidence of the court, and had in his other writings

openly extolled the triumphs and the wisdom of Justinian and Theodora, whose reputation he was the while labouring in secret to destroy. His stories satisfied his first editor, Nicholas Alemannus, and later Gibbon and Dahn; but it may be remembered that there is not a word of Theodora's profligacy in Evagrius or Zonaras, and moreover that, when a man owns that elsewhere he has purposely denied or concealed the truth, it may at least be said that we are entitled to hesitate about the value of his testimony at all.

See Antonin Débidour, *L'Impératrice Théodora* (Paris, 1885); C. E. Mallet's article in *Eng. Hist. Rev.* (vol. ii. 1887); F. Dahn's *Prokopius von Cäsarea* (Berlin, 1865); Bury's *Later Roman Empire* (1889). Sardou's drama on the theme (1884) revived interest in the puzzling personality and character of the great empress.

Theodore OF MOPSUESTIA, a great exegete of the early church, was born at Antioch about the middle of the 4th century. He was the friend of Chrysostom and the pupil of Libanius, but it was Diodorus of Tarsus from whom he imbibed his zeal for biblical studies. About the year 383 he became a presbyter in Antioch, and about 392 he was chosen Bishop of Mopsuestia in Cilicia. He died at peace with all men in 428 or 429. Theodore wrote commentaries on almost all the books of Scripture, of which only remain, in the Greek, that on the Minor Prophets; in Latin translations, those on the lesser epistles of Paul, besides many fragments, especially on the epistle to the Romans. As an exegete he eschews the allegorical method, adopting the literal meaning, and he takes into consideration also the historical circumstances of the composition, and assumes varying degrees of inspiration. When the Nestorian controversy broke out his polemical writings, which seem to have offended by a characteristically sober tone, were attacked, and after a century of fanatical agitation were formally condemned by Justinian in the *Tria Capitula* (544). The fifth œcumenical council—that of Constantinople in 553—confirmed the emperor's condemnation, and Theodore's name vanished from the list of orthodox writers.

The Greek fragments of his New Testament commentaries were collected by Fritzsche (1847). The Pauline commentaries were edited by Swete, with admirable prolegomena (Camb. 1880-82). The commentary on the Minor Prophets was edited by Wegnern (1834) and Mai (1832, 1854), the Syriac remains by Sachau (1869). See Kihn, *Theodore von Mopsuestia u. Junilius Afric., als Exegeten* (Freib. 1880).

Theodore, 'king of Corsica,' otherwise Baron Theodore de Neuhoff, son of a Westphalian noble in the French service, was born at Metz in 1686, was himself successively in the French, Swedish, and Spanish service, was ruined in Law's speculations, and after leading an adventurer's life settled at Florence in 1732. As representative of the Emperor Charles VI., he was induced by Corsican acquaintances to head a Corsican rising against the Genoese; and with the support of Turkey and a ship and munitions from the Bey of Tunis landed in Corsica in March 1736, and was crowned Theodore I. He was in a few months driven to flight, as he was again on a second attempt in 1738, and on a third in 1743. After many wanderings he settled in London in 1749. Imprisoned by his creditors, he was liberated by a subscription supported by Walpole, but died soon after, 11th December 1756. In Spain he had married an Irish lady, daughter of the Earl of Kilmallock. His only son by her, known as Colonel Frederick, wrote a book on Corsica, and at the age of about seventy-two shot himself in the porch of Westminster Abbey, 1st February 1797. See Fitzgerald, *King Theodore of Corsica* (1890).

Theodore. See ABYSSINIA.

Theodoret, church historian, was born at Antioch about 390, early entered a monastery, and in 423 became Bishop of Cyrus, a city of Syria. Here he laboured with the utmost zeal, and he himself claims to have converted over a thousand Marcionites. As a foremost representative of the school of Antioch he became deeply involved in the great Nestorian and Eutychian controversies, and was finally deposed by the celebrated Robber-council of Ephesus in 449. This was reversed by the general council of Chalcedon in 451, but Theodoret did not long survive his restoration, dying about 457.

His works were edited by Schulze and Nösselt (Halle, 1769-74), and consist of commentaries on Canticles, the Prophets, Psalms, and the whole of St Paul's Epistles; a *History of the Church*, from 325 to 429 A.D., in five books, ed. by T. Gaisford (1854), trans., with Evagrius (1851); *Religious History*, being the lives of the so-called Fathers of the Desert, a series of most curious and interesting pictures of early ascetic life; the *Eranistes*, a dialogue against Eutychianism; *A Concise History of Heresies*, together with orations and nearly 200 letters. See Binder, *Études sur Théodoret* (Geneva, 1844); Specht, *Theodor von Mopsuestia und Theodoret von Cyrus* (Mun. 1871); Roos, *De Theodoreto Clementis et Eusebii compilatore* (Halle, 1883); and A. Bertram, *Theodoreti Doctrina Christologica* (Hildesheim, 1883).

Theodoric, or THEODERIC (455–526 A.D.), surnamed THE GREAT, was the founder of the Ostrogothic monarchy. The history of his reign is given at GOTHS, Vol. V. p. 322. To the Germans he is known as Dietrich von Bern (Bern being the German name for Verona, one of his principal residences), and is one of the great heroes of old Germanic legend, figuring in the second part of the *Nibelungenlied*. In some of the legends the historical element predominates (his expulsion from Italy and sojourn with Attila and his Huns, &c.); in others he is mixed up with giants, dwarfs, and dragons, so that it seems likely the series comprise, along with tales of the king Theodoric, mythological elements that properly belonged to the god Thor. See Hodgkin, *Theodoric* (1891).

Theodosia. See KAFFA.

Theodosius THE ELDER, a Spaniard by birth and a skilful Roman general, was sent to Britain in 367 A.D. to repel the inroads of the Caledonians and restore order to the diocese. He made London his headquarters, and was so successful in his undertaking that he formed the country between Hadrian's Wall and the Forth and Clyde into a new province of the empire, called *Valentia* in honour of the reigning emperors. After a victorious campaign on the Upper Danube against the Alemanni he quelled a formidable revolt in Africa under Firmus the Moor, and was executed at Carthage in 376 upon some unknown and probably groundless charge.

Theodosius I., THE GREAT, son of Theodosius the Elder, was one of the most notable and most capable of the later Roman emperors. Born about 346 at Cauca in the north-west of Spain, he served under his father in Britain, Germany, and Africa, and won fame as a general by his exploits in Mœsia. Upon his father's death he retired to his native farm, whence he was summoned by Gratian to become his colleague in the purple and emperor in the East (379). It was a critical time. The Goths (q.v.), too numerous and formidable to be attacked *en masse*, flushed too with their recent Cannæ-like victory at Adrianople and the total defeat of his predecessor Valens, were roaming the country at will, unchecked masters of the situation. His military reputation was equal to the strain. He made Thessalonica his headquarters, and within four years, through patience and tact, after reviving the spirits of the imperial

troops by small but decisive victories, he broke up the vast Gothic army, attached many of its members to the empire as faithful soldiers and allies under their own chiefs, and restored tranquillity to the troubled country south of the Danube. A serious illness in 380 led to his baptism as a Trinitarian, and, as a consequence, to the restoration of the religious unity of the empire and the promulgation of various edicts against Arianism and other heresies. He appointed Gregory Nazianzen Archbishop of Constantinople, and summoned the second general council, which met there (381) to supplement the labours of Nicæa. The murder of Gratian at Lyons, the advance towards Italy of the upstart Maximus, proclaimed emperor in Britain, and the arrival of Valentinian II. (with his mother Justina and his sister Galla) begging for help led to Theodosius' marriage with Galla, to his victory at Aquileia (388), and to the restoration of his youthful colleague. Hereafter for some years Theodosius lived at Milan enjoying the friendship and respect of its bishop, St Ambrose. The relationship of those two great men—foremost respectively in state and church—honourable to both and dramatic in its climax, is one of the most interesting features of Theodosius' reign. Theodosius was able, just, even generous, virtuous, and religious, but inclined to indolence and of a passionate temper. He had cancelled, upon the entreaties of its bishop and the penitence and humiliation of its leading citizens, the severe measures meted out to Antioch after a riot (387) in which the imperial statues had been contemptuously overthrown; but in 390, when the governor of Thessalonica was lynched by a circus mob for his punishment of a brutal but favourite charioteer, Theodosius, in spite of expostulations, ordered the people of the city to be invited into the circus and there massacred. At least 7000 were thus put to death. Thereupon Ambrose wrote to Theodosius upbraiding him with the deed, and even after some time had elapsed fearlessly withstood his attempt to enter the church at Milan. The bishop only readmitted the emperor to the sacrament after eight months' retirement and public penance performed in the face of the whole congregation. In 392 Valentinian II. was murdered, and in 394 Theodosius, then at Constantinople, again marched westwards, this time against the Frankish general Arbogast and his puppet emperor Eugenius. After a stubborn fight at the river Frigidus, lasting two days, Theodosius gained a complete victory, and for four months ruled as sole Roman emperor. He expired in the arms of Ambrose on 17th January 395—a date memorable in the history of the later Roman empire, for almost immediately thereafter followed the barbarian invasions of Greece and Italy, which led directly to the subsequent Teutonic settlements in the south and indirectly to the formation of the kingdoms of modern Europe. For Theodosius II., see BYZANTINE EMPIRE.

Theodule Pass. See ZERMATT.

Theognis, a Dorian noble of Megara, flourished about the middle or in the later half of the 6th century B.C. His lot was cast in a troubled time. The overthrow of the tyrant Theagenes brought oligarchy and democracy face to face, and produced a period of confusion and struggle, during which Theognis was driven from his native city. Before his return he had visited Eubœa and Sicily. Under his name two books of elegiacs have come down to us numbering together about 1400 lines. Most of his political verses are addressed to a young Megarian noble named Cyrnus, on whom he seeks to impress the orthodox doctrines of Dorian aristocracy. The oligarchs are the 'good;' the commons the 'bad.' At dinner Cyrnus must sit as near as possible to a good man, so as to carry off some benefit from what he says. The growing influence of wealth disturbs his vision of the future. 'Money mixes race;' but such marriages are the bane of the city. His conclusion is that 'the best thing for a man is not to be born into the world at all, and the next best thing is to die at once.' His social verses present him in a less melancholy mood. Here too the didactic element plays a large part, though his wisdom is more worldly than moral. It is a disgrace to be drunk when the company are sober, but also a disgrace to be sober when the company are drunk, and the ideal stage is that of being 'no longer sober and yet not very drunk.' Cyrnus must suit his demeanour to his company. 'Amongst the uproarious,' says Theognis, 'I am very uproarious, and amongst the proper no man more proper than I.' Cyrnus must 'exceed in nothing; the mean is best in all things.'

For beauty of thought, expression, or imagery we must look elsewhere than in the elegiacs of Theognis. Passion there is none, nor do the profound problems of life which filled the drama of a later age seem to have touched the poet's simple Dorian mind. But his shrewd common sense recommended him to conservative fathers as an authority for their children's instruction, and his wise sayings were so well known that it became a proverb, 'I knew that before Theognis was born.' See Hookham Frere's *Theognis Restitutus* (Malta, 1842).

Theogony, the name given in ancient Greece to a class of poems recounting the genealogy of the gods. Musæus (q.v.) is said to have written the earliest Theogony; but his work, as well as the Theogonies of Orpheus (q.v.) and others, have perished, that of Hesiod (q.v.) being the only one that has come down to us. The story of Creation (q.v.) is on the other hand called COSMOGONY.

Theology (Gr. *theologia*), a doctrine as to the Divine nature and operation. The word first occurs in Plato and Aristotle, who understand by it the doctrine of the Greek gods, and of their relation to the world. Homer, Hesiod, Orpheus, &c. are called *theologoi* ('theologians') on account of the subject-matter of their verse. In the New Testament the word theology does not occur; the Greek Christians originally designated any deep philosophical apprehension of the truths of religion by the term *Gnosis* ('knowledge'), which was opposed to *Pistis* ('faith'), the simple irreflective trust of the majority of humble believers. First during the 3d and 4th centuries the word theology came into use, especially in connection with such of the Fathers as defended the doctrine of the deity of the Logos; in this sense the evangelist John and Gregory of Nazianzen were termed *Theologians.* Scholasticism understood by theology the whole complex of Christian doctrine—to which in England the name divinity is often given.

Natural theology, as discoverable by the light of reason alone, is distinguished from *Positive* or *Revealed* theology, based on the study of divine revelation. Theology is frequently divided into (1) *Historical* theology, treated in this work at CHURCH HISTORY (including history of Dogma); (2) *Exegetical* and *Biblical* theology (see EXEGESIS, BIBLE); (3) *Apologetical* theology, or the evidences (see APOLOGETICS); (4) *Practical* theology, including homiletics, pastoral theology, liturgics, and theories of church government; (5) Theology proper—that is, *Dogmatic*, systematic, or speculative theology. A further subdivision according to the special subject-matter discriminates between theology in the etymological sense as the doctrine of God the Father from Christology, the doctrine of the person of Christ; Pneumatology, or the

doctrine of the Spirit; anthropology, or the doctrine of man; soteriology, the doctrine of redemption by incarnation and atonement; ecclesiology, the doctrine of the church; and eschatology, or the doctrine of last things, of rewards and punishments in a future life. Other sections are biblical archæology, biblical psychology, theological or Christian ethics, and symbolics or the doctrine of creeds.

Dogmatic Theology, or Dogmatic, is the systematic exposition of the dogmas in which the faith of the Christian church has found its historical expression. Down to the end of the 17th century it was for the most part associated with Ethics (q.v.), and the two were combined as *sacra doctrina* or *Theology*, but from that time the separation became general, and the name *dogmatica theologia*, first used by the Lutheran Buddæus in 1724, was applied to the theoretical part of Christian doctrine. It is the main part of theology, combining the results of exegetical and historical inquiry which relate to faith as such. Dogmatic takes these results, brings out their organic connection with the facts of Christian consciousness, and gathers them into a coherent whole, which it presents as the sum of Christian truth in the form suited to the church's present need. It is not a product of the religious consciousness of the individual, but is drawn from those historical sources in which the Christian consciousness of the church has expressed itself in a form accepted as authoritative by the church, or a particular section of it. The churches of the Reformation recognised the Scriptures as the only source of knowledge as to the Christian faith. The orthodoxy of the 17th century, which laboured to bind the human spirit to the letter of Scripture by the fetters of a new scholasticism, was largely displaced in the 18th by the development of philosophical and historical science; and in the 19th the reconciliation of religion and science, the deepest Christian faith and the freest human culture, was initiated by Schleiermacher. With his *Glaubenslehre* begins the modern development of dogmatic, which is devoted to the investigation of the Christian faith as founded on religious experience, and to the study of doctrine for its religious and moral interest, apart from the questions of physical and metaphysical science in which the earlier theologians involved them. The division of dogmatic that has been most followed is by that known as the 'local' method, which treated the subject in separate parts, regarded as the articles (*articuli*, 'joints') of a *corpus dogmaticum*. Melanchthon in his chief work on dogmatic (*Loci communes*) adopted this traditional plan, and was also followed by later Protestant writers. In the 17th century Cocceius and Vitsius introduced the 'federal' method, in which the matter was divided according to the covenants (*fœdera*) which God entered into with man, distinguished as the covenant of nature or of works, and the covenant of grace, with its three economies—before the law, under the law, and after the law. The speculative theologians, Marheineke, Martensen, and Strauss, chose a threefold division as drawn out by Hegel, making the doctrine of the Trinity the basis of distribution. The attempt of Schleiermacher (in which he was followed by Rothe) to treat dogmatic simply as a historical science, giving a systematic account of the doctrines recognised as authoritative in a Christian community at a given time, led to new points of view in the division of dogmatic. Thus Rothe arranges the whole subject under two heads, the consciousness of sin, and the consciousness of grace. Of the earlier writers on dogmatic must be also named Calvin, and after him Ames, Turretin, Mastricht, and the Arminian Limborch, and the Lutherans Hütter, Calovius, Calixtus, and Gerhard. Hill's *Lectures on Divinity* (1821) was the first noteworthy treatise on the subject published in English. Chalmers' *Institutes of Theology* is merely a suggestive sketch. Anglican systematic theology is usually in the form of expositions of the Creed or of the Articles. Among notable modern systems of dogmatic must be noted the *Systematic Theology* of the American Calvinistic Presbyterian, Dr Charles Hodge (3 vols. 1872–73). Gretillat's *Exposé de Théologie Systématique* (4 vols. 1885–92) is an important recent work.

Of other modern writers the chief are De Wette, Hase, Twesten, Nitzsch (Eng. trans. Edin. 1849), Lange, Martensen (Eng. trans. Edin. 1866), Schenkel, Scholten, and Dorner; together with Ebrard, Thomasius, Philippi, Kahnis, Hoffmann, Luthardt, Oosterzee, Nitsch, and Achelis, who treat the subject from a more strictly confessional point of view; the speculative theologians Daub, Weisse, and Heinrich Lang; and the Roman Catholics Hermes, Baader, Klee, Staudenmaier, Günther, and Peronne.

See Rothe, *Zur Dogmatik* (2d ed. 1869); Schöberlein, *Das Princip und System der Dogmatik* (1881); Hagenbach's *Encyclopädie und Methodologie der Theologischen Wissenschaften;* Dorner's *Geschichte der Protestantischen Theologie;* Shedd's *History of Christian Doctrine;* and the theological encyclopædia of Herzog (q.v.). For the biblical theology of the Old Testament there are the works of Oehler and Schultz; for the New Testament, Schmid, Weiss, Immer, and Reuss's *Histoire de la Théologie Chrétienne au Siècle Apostolique.*

Many of the theological articles in this work, besides those above mentioned, will be found in the lists appended to CHURCH HISTORY and ROMAN CATHOLIC CHURCH. See also the articles on the several books of the Bible, those on the apostles and great Christian teachers, the paragraphs on the churches of the several countries, and the following:

Theophany (Gr., 'appearance of God'), specially the appearance of God to the patriarchs in the form of an angel or in human form; also the incarnation and second coming of Christ.

Theophilanthropism, a deistical system of religion drawn up under the French Directory in 1796, and designed to take the place of Christianity, which had been abolished by the Convention. God, virtue, and the immortality of the soul were the main elements of the creed; the services were simple to baldness. The system finally disappeared about 1802.

Theophilus, a legendary coadjutor-bishop at Adana in Cilicia, who, when deposed from his office through slanders, gave his soul in bond to the devil, and consequently was reinstated the next morning. But he was soon overtaken with remorse, and through forty days' fasting and prayers prevailed on the Virgin to make intercession for him. She tore the bond from the devil, and laid it upon the breast of the repentant sinner as he lay asleep in the church. Theophilus then made a public confession of his crime and of the mercy of the Virgin, and died three days after. This forerunner of the Faust legend must have reached the West during the 10th century. It was treated by Roswitha, by Hildebert of Tours, and in a 14th-century Dutch metrical version (published by Blommaert, Ghent, 1836). The first dramatic handling of the subject was in French by

Rutebeuf (q.v.); then repeatedly during the 14th and 15th centuries in Low-German (*Theophilus, in Icelandic, Low-German, and other Tongues*, by Dasent, Lond. 1845). See A. Ebert, *Allgemeine Geschichte der Literatur des Mittelalters*, iii.

Theophilus, Bishop of Antioch from 168, wrote (180–181) in three books, addressed to a pagan friend Autolycus, an apology for Christianity (ed. by Otto in *Corpus Apologetarum*, vol. viii. Jena, 1861). The genuineness of a commentary on the gospels is defended by Zahn, assailed by Harnack.

Theophrastus, naturalist and philosopher, born at Eresos, in the island of Lesbos, probably 373 or 368 B.C., repaired, after an excellent education, to Athens, where he heard Plato and Aristotle, attaching himself particularly to the latter, whose intimate friend and successor he became. He accompanied his master to Stagira, and inherited, by will, the whole Aristotelian library, the largest then known, including the philosopher's original manuscripts and unpublished writings. As head of the Peripatetic school he displayed an all-round versatility not unworthy of Aristotle himself, and was the reputed author of 227 works. His authority remained for many years paramount in logic, psychology, ethics, politics, rhetoric, physics, and metaphysics, in all of which subjects he preserved the lines of his predecessor, while supplementing most of them wherever they seemed defective. His writings are in great part lost, particularly the valuable zoological series in which he dealt with the instincts and habits of animals; but we still possess his *History of Plants*, his *Causes of Plants*, his treatises on *Stones* and on *Fire*. In his hands ancient botany attained its highest development, and after him it seems to have been cultivated only in its relation to medicine. His *XXX. Characters* is another of his extant works—a masterly delineation of moral types, which, however, some scholars assume to be a later compilation from a more discursive original of his. His death is fixed at 286 B.C., after directing for a whole generation the Peripatetic school, which attracted many disciples from all parts of the Hellenic world. As its permanent seat of instruction he bequeathed to it his house, garden, and colonnades.

For a full and accurate review of his writings as a naturalist, see *Die Pharmacie bei den alten Culturvolkern*, by Dr J. Berendes (vol. i. 1891), and for his position in Ethics the masterly edition of the *Characters*, with introduction and trans. by Professor Jebb (1878). The best editions are those of Schneider and Vimmer. See also Usener's *Collectanea Theophrastea*.

Theophylact, a famous Greek exegete, a native of Euripus in Eubœa, who became Archbishop of Achrida in Bulgaria in 1078, and died after 1107. He wrote commentaries on almost the whole Bible, printed in Venice (3 vols. 1754–58).

Theosophy, literally divine wisdom (*theos, sophia*), is a name that since the time of Ammonius Saccas, in the third century after Christ, has been used in the West to cover various schools of religious philosophy, which all unite in the fundamental conception that man, in his innermost nature, is a spiritual being, one in his essence with the Universal Spirit manifested in and through the universe. In this general sense it has been taken to include mystics differing widely from each other in details; among these are the Simonian, Ophite, and Valentinian schools of so-called Gnosticism; the Neoplatonist of Ammonius Saccas, Porphyry, Plotinus, Iamblichus, and Longinus; the great Hermetic and Rosicrucian orders, which kept an unbroken tradition through mediæval and modern Europe; together with the teachings of men like Jakob Boehme, Henry Vaughan, and Law. These may be taken as representing the Occidental stream of Theosophical thought, which has naturally acquired a Christian tone in its symbolism, whereas the Oriental has utilised the symbolism of the great eastern religions. In the East the system now called Theosophy has been known for ages under the titles of Âtmâ Vidyâ ('spirit science'), Brahmavidyâ ('science of Brahma'), Gupta Vidyâ ('secret science'), and other similar names. All alike, in East and West, draw their inspiration and their methods from the 'Wisdom Religion,' the ancient esoteric philosophy. This claims among its initiates the men who have given to the world fragments of the teaching as basis for world-religions, men like Buddha, Confucius, Zarathustra, Pythagoras, Plato, Jesus, to say nothing of yet more ancient sages, Manu, Nârada, and other great Rishis. In the 16th century Paracelsus and Giordano Bruno are among its grandest exponents, and in our own day its messenger was a woman of Russian birth, Helena Petrovna Blavatsky (1831–91), who was initiated in Tibet, and whose works form the most complete exposition of the esoteric philosophy.

The Esoteric Philosophy, or Wisdom Religion, is a body of teaching, philosophical, scientific, and religious, which is believed to be preserved from generation to generation by a brotherhood of initiates scattered over the world, but preserving close and intimate relations with each other. It is to a group of these now stationed in Tibet that the founding of the Theosophical Society in 1875 is ascribed, and it is these who are constantly referred to in Theosophical literature as Mahâtmas, Arhats, Masters, Brothers, or Adepts. They are living men, who have evolved the spiritual nature until the physical body and brain-consciousness have become ductile instruments for the spiritual intelligence; and who, by virtue of this evolution, are said to have gained a control over natural forces which enables them to bring about results that appear to be miraculous. The possibility of this evolution, and the nature of the powers inherent in the highly evolved man, derive inevitably from the postulates of the esoteric philosophy.

This philosophy teaches as basic principles an eternal existence beyond human cognition, existence *per se*, absoluteness or 'be-ness.' A periodical aspect of this is life, consciousness, manifesting itself in and as the universe, primarily emanating as the dual root-substance, matter on its negative, and spirit, or energy, on its positive side. This duality is the note of the manifested universe, manifestation being held to be impossible without the 'pairs of opposites,' positive—negative, active—passive, light—darkness, &c., ultimating at one part of the chain of evolution in sex-difference, male—female. Spirit and matter are therefore not separable, but are merely the opposed poles of the one root-substance, and are present in every particle, as the poles in each fragment of a broken magnet. Evolution consists in the gradual densifying of the root-substance through seven stages or planes of differentiated existence, the matter aspect becoming more and more prominent as the evolution proceeds, and the spirit aspect becoming more and more hidden; thus matter reaches its fullest differentiation, evolving the whole of its capacities as a vehicle. From this point of completest materiality begins the returning curve, during which matter becomes translucent to spirit, and spirit becomes self-conscious on all planes; having manifested itself as brain-intellect on the most material plane, it recovers all its subtler super-intellectual powers on the ascending arc, but always with the addition of self-consciousness and individuality, until, at the completion of the cycle, matter has become a perfect objective presentment of spirit, a perfect vehicle of spiritual activity.

The seven stages of cosmical evolution, aspects of the universal Divine consciousness, correspond with seven stages of human evolution, aspects of the human consciousness, by each of which man can cognise directly the corresponding cosmic state. These in man are distinguished as (1) Âtmâ, pure spirit, one with the universal spirit; (2) Buddhi, the vehicle of Âtmâ and inseparable from it, sometimes spoken of as the spiritual soul; (3) Manas, the mind, the ego or individualising principle, sometimes called the rational or human soul. These three are the immortal part of man, Manas striving for union with Buddhi, such union making the spiritual ego, the spiritual man perfected. The remaining principles form the quaternary, the perishable part of man. These are (4) Kâma, the emotions, passions, and appetites; (5) Prâna, the vitality; (6) Linga Sharîra, the astral double; (7) Sthûla Sharîra, the physical body. [These principles are generally numbered in reversed order, starting from the physical, Sthûla Sharîra being taken as 1 and Âtmâ as 7.] At death, it is taught, the physical body and the astral double disintegrate together; the vitality returns to the universal life; the passional nature, in its own ethereal envelope, exists for a longer or shorter period, according as it dominated, or was subservient to, the higher nature, but ultimately fades away. The higher triad has, during earth-life, been joined to the lower nature by Manas, the mind; this Manas is divided into higher and lower, the higher striving upwards, the lower entangled with Kâma, and held by the desire for material life which is at the root of all manifestation. At death the higher triad gradually separates itself from the lower nature, the lower mind, which is but a ray of the higher, returning to its source, carrying with it the experiences gained during incarnation; the triad, with this added experience, the harvest of life, enters on a period of repose, the state of Devachan. A state of consciousness apart from the physical body, in which the intelligence is free from physical limitations, is one but dimly apprehended by those who are accustomed to confine their ideas of life to the physical world, or to a spiritual world which is merely a sublimated reflection of the physical. Devachan is not a place; it is a state of consciousness in which the experiences of the lately concluded earth-life are assimilated, its best aspirations have their fruition, and the communion of the consciousness with other consciousnesses is freed from physical limitations, and is more complete and satisfying. This state endures for a period proportionate to the stage of evolution reached on earth, and is concluded by the re-entry of the consciousness into the embodied condition.

For the method of evolution, according to Theosophy, is Reincarnation. The reincarnating ego, the agent in progress, is the Manas. In the far-off past, when physical evolution, guided by the indwelling spirit, had produced man's physical form, Manas first became incarnate therein, and has since reincarnated after each devachanic interlude. Throughout each incarnation it labours to evolve in the body it inhabits the capacity to respond to its impulses, but it is through the moulding of successive bodies that it accomplishes its task of human elevation. The thoughts produced by its activity are real *things* on the mental plane, made of subtle matter, 'thought-stuff,' a form of ether. The thoughts of each life ultimate in a thought-body, that expresses the result of that incarnation, and this thought-body serves as a mould into which is built the physical body which forms the next dwelling of the ego. The 'innate character' which the child brings into the world is this result of its own past, and is physically expressed in its brain and nervous organisation. The reincarnating ego is drawn by affinity to the nation and family fitted to supply the most suitable physical material and psychical environment. The physical particles thence supplied are stamped with the racial and family characteristics, bodily and mental, but their arrangement is dominated by the thought-body resulting as above stated. Thus mental and moral capacities gained by struggle in one or many incarnations become innate qualities, exercised 'naturally,' without effort, in a later incarnation, and thus progress is secured. This law, by which all causes work out their due effects, is called Karma (the Sanskrit word for action), and according to this all thoughts, good and bad, leave their traces on the thought-body and reappear as tendencies in future lives. No escape from this sequence of cause and effect is possible; all our past *must* work itself out, but as the same agent that made the past is making the present it sets up fresh causes in meeting the effects of the past. Thus a trouble, generated by past action, is inevitable; it is in our Karma. But we may meet it badly, and so set up fresh cause for bad Karma in the future; or we may meet it well, and so generate good Karma. We made our present destiny in our past, and we are making our future destiny in our present.

The teaching of Reincarnation as the method, and Karma as the law, of evolution leads to the doctrine of universal brotherhood, which it is the object of Theosophy to realise. Offspring of the universal life which is the soul of the universe, bound inextricably together by the ties of Karma, evolving to one common goal of perfect humanity, how should men be aught but brothers? Reincarnation crushes out all differences of race, sex, class; Karma so interweaves human lives that each can only find happiness and perfection as all find it. These facts in nature yield, it is claimed by Theosophy, a scientific basis for ethics, and make the practical recognition of human brotherhood a necessary condition of accelerated evolution.

Besides the works of Paracelsus, Bruno, and Boehme the student should consult H. P. Blavatsky's *Secret Doctrine, Isis Unveiled, Key to Theosophy, Voice of the Silence;* the present writer's *Seven Principles of Man, Reincarnation;* A. P. Sinnett's *Esoteric Buddhism;* W. Q. Judge's *Echoes of the Orient;* for the Christian aspect, Dr Anna Kingsford's *Perfect Way, Woman clothed with the Sun* (Theosophical Publishing Society, 7 Duke Street, Strand, London). There is a very large pamphlet literature. The Theosophical Society has its headquarters at Adyar, Madras, India, where a monthly periodical, *The Theosophist*, is published. European headquarters are at 17 and 19 Avenue Road, London, N.W., and the leading European monthly magazine is *Lucifer*, published at 7 Duke Street as above. American headquarters are at 144 Madison Avenue, New York, and there a third monthly, *The Path*, is published. There are nearly 300 branches of the society scattered over the world.

Therapeutæ (Gr., 'worshippers'), an ascetic sect, mentioned in the *De Vita Contemplativa* long ascribed to Philo as living chiefly on the Lake Mareotis, near Alexandria. Their discipline resembled that of the Essenes, but was more severe in food and in the preference for the solitary life to the common fellowship. Throughout the week each lived in his lonely dwelling (*μοναστήριον*), but on the Sabbath they assembled for worship. The sole authority for their existence, the *De Vita Contemplativa*, is not believed to be Philo's, although Conybeare (in his edition, 1895) and others have defended his authorship. It seems rather to be the work of a Christian, written about 300 A.D.—an imaginative idealisation of the life of Christian monasticism and asceticism of the time. See P. E. Lucius, *Die Therapeuten* (Strasburg, 1879).

Therapeutics (Gr. *therapeuō*, 'I heal') is that division of the science of medicine which treats of the various actions of remedies upon the diseased animal system, or the means by which nature may be aided in her return to health. 'Suggestive Therapeutics' is a term for Hypnotism (q.v.) employed as a sanative agency.

Therapia, a Turkish town of 3000 inhabitants, finely situated on the Bosporus, 15 miles NE. of Constantinople. It is the summer residence of the ambassadors and Frankish merchants.

Theresa, St. See Teresa.

Theresiopel. See Szabadka.

Theriaca (Gr., from *thērion*, 'a wild beast'), a medicine in the form of an electuary, supposed to be an antidote to the poison of venomous animals. It is said to have been invented by Andromachus of Crete, physician to the Emperor Nero; and was a mishmash of about seventy ingredients, some of them quite inert, and others antagonistic to one another. Yet it continued in repute until recent times; in Venice, Holland, France, and elsewhere the druggists had for centuries to prepare the compound with certain solemnities in the presence of the magistrates. The term was applied to various compounds of a similar nature, and *theriac* and *theriacal* became synonymous with medicinal. The English word *treacle* is a corruption of *theriacal*, and originally meant an electuary, or compound syrupy medicine; and it was applied to molasses from the similarity in appearance.

Thermidor, i.e. the 'Hot Month,' formed, in the calendar of the first French Republic, the 11th month, and lasted from the 19th July to the 18th August. The 9th Thermidor of the Republican year 2 (July 27, 1794) is historically memorable as the date of Robespierre's fall, and the termination of the Reign of Terror. The name Thermidorians was given to all those who took part in this fortunate *coup d'état*, but more particularly to those who were desirous of restoring the monarchy.

Thermodynamics is the branch of physical science which discusses the relation between heat and work. It forms the kernel of the modern doctrine of Energy (q.v.); for it was by the discovery that heat was energy and not matter that the conservation principle was established in its widest generality. Towards the end of the 18th century Davy and Rumford had independently shown that the caloric theory of heat was untenable. But it was not till thirty or forty years later that the scientific mind began to emancipate itself from this theory which regarded heat as an imponderable substance effecting thermal changes by combination with ordinary ponderable matter. With the early development of the true theory the names of Colding, Hirn, Joule, and Mayer are closely associated. The labours of Joule (q.v.) were particularly valuable, as he it was who first in 1843 obtained a really good measurement of the mechanical or dynamical equivalent of heat—that is, the amount of dynamical work which is equivalent to a given quantity of heat. This equivalent is commonly called Joule's Equivalent. By demonstrating experimentally that wherever energy in the dynamical form is lost an exact equivalent of heat is always obtained, Joule established what is known as the First Law of Thermodynamics. Briefly put, this law is the statement that heat is energy, and can be measured in the same units. When during any transformation of energy heat is generated, it is at the expense of an exact equivalence of energy in some other form. Or when, on the other hand, there is a disappearance of heat, an exact equivalence of energy in some other form or forms will appear.

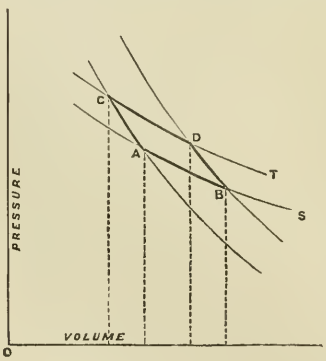
It is a familiar fact that relative motion is destroyed by friction. But destruction of motion means loss of kinetic energy; and it is this lost energy which is transformed into the heat invariably produced by friction. There is no difficulty in effecting the transformation of other forms of energy into heat. It is impossible, indeed, to prevent some of the energy taking the form of heat whenever a transformation is effected—whenever, in other words, any change of physical conditions occurs. But whatever be the manner of the transformation, the first law of thermodynamics is found to be always fulfilled, the amount of heat generated is equivalent to the energy, in other forms, which has disappeared. Joule's earliest determination of the dynamical equivalent of heat differed by only $\frac{1}{2}$ per cent. from his latest, made in 1878. This last result has probably not been excelled in accuracy by any later experimenter. According to it the quantity of heat capable of raising the temperature of a pound of water, weighed *in vacuo*, from 60° to 61° Fahrenheit requires for its evolution an expenditure of work represented by the fall of 772·55 pounds through a distance of one foot at the sea-level at the latitude of Greenwich; or the dynamical equivalent of the unit of heat defined as above is 772·55 foot-pounds at Greenwich. The scientific unit of heat is now taken to be the amount of heat required to raise 1 gramme of water from 0° to 1° centigrade. Hence, reducing to the lower temperature and taking account of the change of thermometric scale, we get for the value of Joule's Equivalent 1391·8 foot-grammes or 42422 centimetre-grammes or $4{\cdot}1623 \times 10^7$ ergs. We may assume these numbers to be correct to four significant figures.

To convert work into heat is an easy matter; but not so the reverse operation, to convert heat into work. This, however, is the function of all our heat engines, using the term in its widest sense as including steam-engines, gas-engines, and all machines which do work by combustion of fuel. It has long been recognised that such machines can work only when there is a difference of temperature. It matters not how much heat may be stored up in a body, it is practically impossible to utilise that heat as working energy unless we have a neighbouring body of lower temperature. But when a difference of temperature exists there is a constant passing of heat from the warmer to the colder body, so that the temperatures tend to become equalised. And thus the very nature of heat is such as to make it lose more and more of its availability for being transformed into useful work. Suppose, however, that it was possible to prevent heat from passing by conduction or diffusion from the warmer to the colder body, and that whatever heat was taken from the system during a suitable series of operations was altogether transformed into work, how does this transformability of the heat depend upon the temperatures? This is the question which is answered by the Second Law of Thermodynamics, the development of which is closely associated with the names of Carnot, Rankine, Clausius, and Thomson (Lord Kelvin).

Sadi Carnot (q.v.), in his famous *Réflexions sur la Puissance du Feu* (1824), clearly laid down the lines along which the complete theory must be developed. His own argument was vitiated by the assumption of the then accepted caloric theory of heat. But we know from his posthumous papers published in 1878 that Carnot himself had, before his premature death in 1832, recognised that heat was energy, and had fully enunciated the First Law of Thermodynamics.

Besides sketching out a series of experiments almost identical with the valuable researches subsequently made by Joule and Kelvin, Carnot made an estimate of the dynamical equivalent of heat, which, though one-sixth too small, was more accurate than Mayer's made in 1842. Carnot is now recognised as one of the greatest scientific men of the century; and had he survived there is no doubt that the theory of heat would have been established nearly thirty years earlier than it was. Carnot's methods, as given in his book, were not appreciated till Kelvin in 1848 drew attention to them. Soon after Clausius, correcting the one flaw in Carnot's reasoning, established the Second Law on its modern basis. To Kelvin we owe the doctrine of the dissipation of energy and the definition of the absolute thermometric scale. By this is meant an energy method of measuring temperature, independent, that is, of the kind of substance used. See TEMPERATURE and THERMOMETER. To make this scale intelligible involves the discussion of Carnot's principle, which is virtually the second law.

The novel feature of Carnot's method was the invention of the cycle of operations, and especially the reversible cycle. An engine or working substance will have passed through a cycle of operations when all its parts have recovered exactly those physical conditions (volume, pressure, temperature, and the like) which they had at the beginning. It is only when such a cycle has been completed that we have any right to reason about the transformations of energy which have taken place during the progress of the operations which constitute the cycle. For simplicity take as working substance a definite quantity of air contained in a chamber, whose volume may be varied indefinitely by the outward or inward motion of a piston. We shall assume that the walls of this chamber can be made either perfectly impervious to heat or perfectly diathermanous. When in this latter condition the substance is to be kept in contact with another substance at the same constant temperature. Volume and pressure changes, which take place in this condition in the working substance, take place *isothermally*, there being no change of temperature. On the other hand, when the impervious condition is realised, whatever changes take place in the working substance take place *adiabatically*, there being no loss or gain of heat. When the temperature of air is kept constant we know by Boyle's law that the pressure varies inversely as the volume. This relation and all similar relations may be represented graphically by means of a curve, every point of which denotes a definite state of pressure and volume. Such a curve is called an *isothermal* line. For any given mass of gas or air there will be a different isothermal line for each different temperature. If we trace a series of isothermals, we can at a glance determine any one of the quantities, temperature, pressure, and volume, when the other two are given. In the figure two isothermals, AB, CD, corresponding to temperatures S and T, are shown. T is supposed to be the higher temperature. Volume is measured horizontally from the origin O, and pressure vertically. The lines CA, DB are supposed to be *adiabatic* lines. They show how volume and pressure vary with one another when heat is allowed neither to leave nor to enter the substance. Just as along each isothermal the temperature is constant, so along each adiabatic there is a quantity called the entropy, which remains constant. Adiabatic lines are also called isentropic. To pass from one isotherm to another we must change the temperature. In like manner, to pass from one adiabatic to another we must change the entropy.



Begin with the working substance in the state A —i.e. with volume Oa, pressure aA, and temperature S. Compress adiabatically till the temperature rises to T and the state C is reached. In this first operation a definite amount of work is done, but no heat is gained or lost. Next, let the substance expand isothermally to any state D, doing work and at the same time taking in heat from the source, which is kept permanently at the temperature T. In the third operation let the substance expand adiabatically until the temperature falls to S and the state B is reached. In this operation a definite amount of work is done by the substance. Finally, compress the substance isothermally until the original state A is reached. Here work is done on the substance, and heat is given out to the refrigerator, which is kept permanently at temperature S. The cycle is now complete. The work done by the working substance or engine is represented by the area ACDB; and this work done must be equivalent to the heat which has disappeared. If Q units of heat are taken in in the second operation (CD), and q units of heat given out in the fourth (BA), Q must be greater than q, and the difference $(Q - q)$ will be dynamically equivalent to the work (W) done by the engine. Now if the engine is reversible in Carnot's sense, it will be possible to go round the cycle in the opposite direction, reversing all the physical processes involved, and generating $(Q - q)$ units of heat by the expenditure of W units of work. Carnot's principle is that this reversibility is the test of a perfect engine. A more efficient engine than the reversible engine cannot exist. To prove this, let N be the reversible engine, and suppose that M is a more efficient engine than N. In other words, M can, with a given supply of heat, do more work than N. The $(Q - q)$ units of heat taken in by M during the cycle will be transformed into $(W + w)$ units of work; and of these W units will be changed back into $(Q - q)$ units of heat by the reversible engine, N, working backwards. Thus in a complete double cycle w units of work will be done, while the heat originally taken from the source at temperature T has been restored to it. To account for this overplus of work we must suppose an equivalent of heat to be taken from the refrigerator at temperature S. Hence if a more efficient engine than the reversible engine existed it would be possible to do work by means of heat taken from the refrigerator. By taking as refrigerator any limited part of the universe, we should be able to cool that part until all heat was removed from it, and so to obtain from it useful work. Such a result is contradicted by all our experience. Hence we conclude that the reversible engine is the perfect engine.

Returning to the cycle of operations, we see that Q units of heat are taken in at the temperature T, and q units given out at the temperature S; and by experience we know that Q and T are greater than q and S respectively. Kelvin's absolute scale of temperature is obtained by defining T and S such that their ratio is the same as Q and q, or

$$q : Q = S : T;$$

this gives $Q - q : Q = T - S : T$.

Now $(Q - q)/Q$ is the ratio of the usefully transformed heat to the whole heat supplied, and is called the efficiency of the engine. Hence the greatest possible efficiency of a heat engine is measured by the ratio of the difference of temperatures of the source and refrigerator to the temperature of the source. This absolute scale is found to be in close accordance with the scale of the air thermometer; and its zero, as determined by Kelvin and Joule, lies 274° centigrade below the freezing-point of water. Thus a perfect engine working between temperatures 0° to 100° C. would have an efficiency of $\frac{100}{374}$, or little more than one-fourth. Practically it will hardly exceed half this value.

Now looking back to the diagram we see that Q is the heat taken in as we pass from the adiabatic CA to the adiabatic DB along the isotherm T, and similarly that q is the heat taken in as we pass between the same adiabatics along the isotherm S. But $Q/T = q/S$, and the same ratio is given by whatever isotherm—i.e. at whatever temperature—we may pass between the adiabatics. We may therefore take this ratio to be the amount by which the entropy increases as we pass from the one adiabatic to the other. The universal tendency of heat is to pass by conduction or radiation from the warmer to the colder body. If, then, H units of heat pass from a body at temperature T to a body at temperature S, the warmer body will lose entropy to the amount H/T, and the colder will gain entropy H/S. S being smaller than T, the gain will be greater than the loss, and hence the entropy of the system will increase by the amount $H(S^{-1} - T^{-1})$. Thus we have Clausius' theorem that the entropy of the universe tends to a maximum. Kelvin's view is slightly different. His doctrine of the dissipation or degradation of energy, otherwise the loss of motivity, will be found discussed under ENERGY. Maxwell has pointed out that if we could deal with the individual molecules of gaseous matter, it would be possible without expenditure of work to raise the temperature of one region and lower that of another, in contradiction to the second law of thermodynamics. Thus it appears that the second law stands on a distinctly different footing from the first law. Its basis is really to be found in the fact that we can deal with molecules of matter only in the aggregate and statistically, and not individually. That it is, nevertheless, essentially involved in many of the processes of nature is shown by the remarkable results which have been obtained by its means. Its consequences have been developed by Rankine, James Thomson, Kelvin, and Clausius, and in later times by Massieu, Gibbs, Helmholtz, and others. Thermo-electricity, radiation, capillarity, the conditions of equilibrium of heterogeneous bodies, the co-existence of different states of the same body, and generally the interrelations of electricity, magnetism, heat, and light, all give interesting illustrations of the second law of thermodynamics.

See Maxwell's *Theory of Heat* and Tait's *Heat* for elementary discussion of the subject, and Tait's *Thermodynamics* for the historical aspect. Bayne's *Thermodynamics* and Parker's *Elementary Thermodynamics* (1891) are the only formal treatises in English. J. J. Thomson's *Applications of Dynamics to Physics and Chemistry* (1888) contains the solution of many complex problems. Clausius' and Kelvin's original papers are still the most important in all thermodynamic literature.

Thermo-electricity. See ELECTRICITY, Vol. IV. p. 275.

Thermometer is a name which, though applicable to any instrument for measuring change of temperature, is usually restricted to such instruments as measure by means of the expansion of substances, and more especially of liquid substances. The ordinary thermometer consists of a glass tube of very narrow bore, which opens out into a bulb at one end. This bulb and part of the capillary tube are filled with the thermometric substance, generally mercury, sometimes alcohol or other liquid, but never water. Mercury is pre-eminently suitable for thermometric purposes. Its freezing-point is lower than the temperatures with which we have usually to deal; and its boiling-point is much higher than that of any other substance which is liquid at ordinary atmospheric temperatures. Throughout a long range it expands very steadily as heat is applied to it. By defining degrees of temperature in terms of equal successive increments of volume of mercury, we get a very serviceable scale, differing but slightly from the scale of degrees as defined thermodynamically by Lord Kelvin (see TEMPERATURE, THERMODYNAMICS). Mercury again is opaque, and does not wet the surface of the glass with which it is in contact. Alcohol and water, on the other hand, are transparent, so that when the former is used as the thermometric substance it has to be coloured. The peculiar behaviour of water near its freezing-point quite condemns its use in thermometry, even if it were suitable in other respects (see HEAT). It would, however, be highly inconvenient otherwise, inasmuch as its freezing and boiling points lie well within the range of easily attainable temperatures. As regards its boiling-point, alcohol has the same disadvantage. It is in the measurement of very low temperatures that alcohol and ether thermometers are particularly valuable. These substances have also the further merit of having a high expansibility.

When the capillary tube and bulb have been constructed, the first operation is to fill in a sufficient quantity of liquid. This is effected by first heating the bulb to expand the air contained in it, and then plunging the open end of the tube into the liquid, which gradually rises through the bore as the air in the bulb cools. The tube is then set with the bulb down and tapped until most of the liquid is shaken out of the tube into the bulb. A second heating of the bulb until the liquid boils still further diminishes the amount of air inside; and more liquid is introduced as in the first operation. The manipulation requires great skill; and the first stage is reached when at ordinary temperatures the required quantity of liquid fills the bulb and part of the tube. The next stage is to seal hermetically the upper end of the tube when it is quite free of air, a condition which is attained by heating the upper surface of the liquid to the boiling-point and so driving out the air. When the sealing is effected the tube and bulb are filled almost entirely with the thermometric substance and its vapour. Probably no thermometer is quite clear of air, for it is difficult, if not impossible, to get rid *absolutely* of the air held in solution in liquids; but the quantity mingled with the liquid or its vapour is excessively minute in the best thermometers.

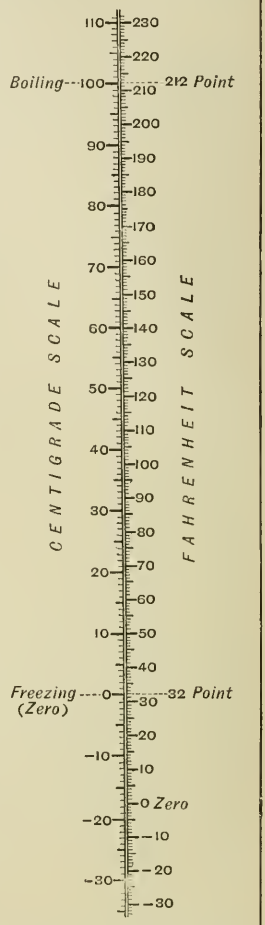
It now remains to graduate the instrument so that its indications may be capable of interpretation. The most delicate thermometers have an arbitrary scale engraved on the tube before the operation of filling is begun; and afterwards certain definite and known temperatures are measured in terms of it, so that its indications become known. For all ordinary and most scientific purposes it is sufficient to engrave the scale on the stem after the positions of the liquid column have been determined for the two chosen standard temperatures. Thermometers with *attached* scales engraved on ivory or brass are useless for other than the roughest determinations.

The two standard temperatures universally used in graduating a thermometer are the freezing and boiling points of water. Previous to the discovery that these, under given conditions, correspond to definite temperatures, thermometry could hardly be said to exist. In Newton's scale of temperature (*Philosophical Transactions*, 1701) the freezing-point of water is taken as zero, and the temperature of the human body as 12°. Fahrenheit, who first in 1721 constructed a mercury thermometer, took as his zero the lowest temperature that had then been reached, and called the temperature of the human body 8°. Each degree was subdivided into twelve parts; and subsequently these twelfths were taken as the degrees. This made the temperature of the body 96°; and it was found that the freezing-point of water was 32°. When shortly afterwards it was discovered that the boiling-point of water was always the same under the same barometric pressure, a second and easily determinable standard temperature was obtained. Thenceforward this boiling-point, under a pressure of 30 inches, was fixed at 212° on the Fahrenheit scale, the freezing-point being as before 32°. With these as standard, the temperature of the body is 98°; so that the present Fahrenheit scale is not exactly that which Fahrenheit himself adopted. Celsius in 1742 suggested that the boiling-point be called zero, and the freezing-point 100°. In the modern centigrade scale, commonly called the Celsius scale on the Continent, the freezing-point is taken at zero and the boiling-point under 760 millimetres pressure (29·92 inches) at 100°. Réaumur divided the interval between the freezing and boiling points into eighty divisions, and this scale is still largely used in Russia and Germany.

The centigrade scale is used almost exclusively for scientific purposes. British and American meteorologists, however, prefer the Fahrenheit scale, which has two distinct merits as compared with the centigrade. Its degree is smaller, so that by reading to tenths the observer has a more delicate instrument. To attain the same accuracy with the centigrade the observer must read to half-tenths. Again, the freezing-point being at 32°, it is only under severe wintry conditions that *negative* Fahrenheit temperatures are met with. So inconvenient is the constant occurrence of negative temperatures on the centigrade scale that it is very usual in continental observatories to write −1°, −2°, −3°, &c. in the form 99°, 98°, 97°, making the freezing-point practically 100°, and the boiling-point 200°. For temperatures above the freezing-point the 'hundred' may be omitted without any fear of confusion.

It is often necessary to transform temperature readings from one scale to another, and more especially from centigrade to Fahrenheit, since the latter scale is the more familiar to English readers. The simplest rule is: Double the centigrade number, diminish it by one-tenth of itself, and add 32. The converse rule for changing Fahrenheit into centigrade is: Subtract 32, increase the remainder by one-ninth of itself, and take the half. In the figure the Fahrenheit and centigrade scales are shown side by side. To reduce Réaumur to Fahrenheit, multiply by 2¼ and add 32. To reduce Réaumur to centigrade, increase the number by one-fourth of itself. These rules are simply expressions of the truth that 9 degrees on the Fahrenheit scale, 5 degrees on the centigrade, and 4 degrees on the Réaumur all measure the same temperature interval.

Various modified forms of thermometer are used for particular purposes. Thus the measurement of the humidity of the atmosphere is effected by means of the *wet-bulb* thermometer. In this instrument the bulb is covered with a woollen material kept constantly wet by the capillary action of its hanging ends, which dip into a vessel of water. When the air is saturated with moisture (see DEW) there will be no evaporation from the moist surface covering the bulb, and the wet-bulb thermometer will give the same indication as the ordinary dry-bulb. In a dry and warm air the water surrounding the bulb will evaporate at a rate depending on the dryness and the temperature. This evaporation is accompanied by a cooling of the evaporating substance and the bulb in contact with it, so that the wet-bulb thermometer will indicate a temperature lower than the temperature of the air as shown by the dry-bulb thermometer. The less humid the air is at a given temperature the greater is the difference of readings on the wet- and dry-bulb thermometers.



The Fahrenheit and Centigrade Thermometer Scales.

Maximum and *minimum* thermometers belong to the self-registering class of instrument. The ordinary clinical thermometer for taking the temperature of the body is one form of maximum thermometer. In it a constriction above the bulb prevents the mercury column flowing back *of itself* into the bulb. Thus the upper end of the column continues to indicate the highest temperature reached until it is shaken down by the operator. For meteorological purposes maximum and minimum thermometers are usually laid horizontal or nearly so. In one form of maximum thermometer the mercury pushes a small index in front of it, which remains indicating the highest point reached after the mercury has contracted because of cooling. In the minimum thermometer the index is set in the alcohol which is used as the thermometric substance. As the alcohol contracts it drags with it the index, whose upper end indicates the lowest point reached by the curved capillary surface of the liquid. For measuring the temperatures at different depths of the sea various devices have been used by which the temperature at any required point can be registered, so that it matters not through what temperatures, high or low, the instrument has to pass before it comes into the hands of the observer. The form used so successfully in the *Challenger* expedition will be found described in the first volume of the Physical and Chemical *Reports*.

Instruments for continuous registration of successive temperatures, or for self-registration of temperatures at short intervals of time, form an indispensable part of the equipment of complete meteorological observatories. The photographic

method is the simplest in which a mercurial thermometer can be employed. Things are so arranged that the sensitive paper, kept steadily moving by clockwork behind the thermometer, can receive only light which has passed through the small bore of the tube above the mercury. When the record has been taken, any point on the line which separates the part of the paper that has been exposed to the light from the part not affected corresponds to the height of the mercury column in the tube at the very instant at which that point on the line lay behind the thermometer. From this record, therefore, any temperature can be picked out at leisure long after the registering of it.

For general convenience and for the certainty of its indications the mercurial thermometer is pre-eminent. Historically older, however, and scientifically superior is the *air* thermometer. As shown in the article Gases (q.v.), the product (pv) of the pressure and volume of a gas is very nearly proportional to the absolute temperature. Hence if we keep the pressure constant, the change of volume will be a direct measure of the change of temperature. The practical difficulty is to keep the pressure constant. It requires indeed a skilful experimenter to manipulate satisfactorily an air thermometer. Such a thermometer is, however, indispensable for measuring the very low temperatures that must be reached before the ordinary gases can be liquefied under great pressure. Leslie's differential thermometer is virtually a U-tube terminated by two balls, whose air contents are separated by spirits of wine filling the bend. In its day it was perhaps the most delicate instrument of its kind; but thermo-electricity (see Electricity) has now provided us with much more delicate methods of measuring minute changes of temperature.

For the measurement of very high temperatures it is necessary to make use of the expansion of solids. Such an instrument is generally called a Pyrometer (q.v.). By suitable contrivances the very small changes of length for moderate ranges of temperature may be so magnified as to make such a metallic thermometer serviceable for ordinary purposes. Certain forms of self-registering instruments used in meteorology are constructed on this principle. A particularly delicate form of metallic thermometer is Bréguet's. It consists of two thin strips of differently expansible metals soldered together, bent into the form of a helix and fixed at its upper end. A horizontal index is attached to the lower end. When the temperature changes, the one strip expands or contracts more than the other and the helix twists or untwists through an angle nearly proportional to the change.

Thermopylæ (lit., 'the hot gates'), a famous pass leading from Thessaly into Locris, and the only road by which an invading army can penetrate from northern into southern Greece. It lies south of the present course of the river Spercheius, between Mount Œta and what was anciently an impassable morass bordering on the Maliac Gulf. In the pass are several hot springs, from which Thermopylæ probably received the first part of its name. Thermopylæ has won an eternal celebrity as the scene of the heroic death of Leonidas (q.v.) and his 300 Spartans in their attempt to stem the tide of Persian invasion (480 B.C.). Again, in 279 B.C., Brennus, at the head of a Gallic host, succeeded, through the same treachery that had secured a victory to Xerxes, in forcing the united Greeks to withdraw from the pass.

Thersites, son of Agrius, whom Homer, in the *Iliad*, makes the ugliest and most impudent of the Greeks before Troy. His name became a synonym for dastardly impudence. Later poets say he was slain by Achilles for calumniating him.

Thesaurus. See Dictionary.

Theseus, the great legendary hero of Attica, son of Ægeus, king of Athens, by Æthra, daughter of Pittheus, king of Troezen, at whose court he was brought up. On reaching manhood he proceeded to Athens, and was recognised by Ægeus as his son and successor. He captured the Marathonian bull, and next delivered Athens from its dreadful tribute of youths and maidens to the Cretan Minotaur, aided by the Cretan princess, Ariadne. When king he consolidated the twelve petty commonwealths of Attica into one state, reorganised the Pan-Athenaic festival, and founded the Isthmian games. He fought the Amazons, and carried off their queen, Antiope or Hippolyta, and after her death married Phædra. Further legends make him take part in the Argonautic expedition, join in the Calydonian hunt, help Peirithous and the Lapithæ against the Centaurs, and join in the attempt to rescue Proserpine from the lower world—an act of monstrous audacity for which he was kept there in close imprisonment till delivered by Hercules. Returning to Athens, he failed to re-establish his authority, and withdrew to Scyros, where he was treacherously destroyed by King Lycomedes; but his shade appeared to aid the Athenians in the fight at Marathon. See Ægeus, Ariadne, Minotaur.

Thespis, the reputed founder (about 540 B.C.) of Greek dramatic representation. See Theatre.

Thessalonians, The Epistles to the. The first epistle to the Thessalonians, the earliest extant epistle of the apostle Paul, was written at Corinth, probably about the beginning of the year 53 A.D., or, at latest, in 54 A.D., within a year and a half of the founding of the church at Thessalonica under the circumstances related in Acts, xvii. 1–10. Some time after leaving Thessalonica, the apostle had heard of 'sufferings' to which his converts there had been subjected by their unbelieving fellow-countrymen (1 Thess. ii. 14; iii. 2–4), and there was some cause for fear lest 'the tempter' had 'tempted' them from their faith (iii. 5). He accordingly sent Timothy from Athens to learn further about their state, and to 'establish' and 'comfort' them (iii. 2, 5). Timothy brought back to the apostle, now in Corinth, a fairly satisfactory account of their faith and loyalty, but mentioned some matters of Christian doctrine and life in which they were deficient; hence the epistle. Of the two parts of which it is composed the first is mainly personal and explanatory (i.–iii.), and the second ethical and doctrinal (iv. v.), warning in particular against sins of impurity, perhaps also of commercial greed (iv. 6), and still more specially against a tendency of the Thessalonians towards pious idleness in view of Christ's imminent second coming and towards a hopeless sorrow on account of those of their number who had already died. With regard to the second coming, the apostle's own doctrine is that it may be expected at any time, and that diligence and watchfulness are therefore necessary; and he clearly anticipated that at latest it would take place before the generation then living had wholly passed away. Baur, who was the first to deny the genuineness of this epistle, has not been followed in this by the more recent representatives of the Tübingen school.

See the commentaries of Jowett, Ellicott, Lunemann (in Meyer), and Schmiedel (in Holtzmann's *Handcommentar*); P. Schmidt, *Der erste Thessalonicherbrief* (1885); and the New Testament Introductions of Bleek, Hilgenfeld, Reuss, Holtzmann, and Weiss.

The second epistle consists of three parts. The first part is introductory, and mainly an expression of the writer's thankfulness for the steadfastness the Thessalonians have displayed under continued persecution (i. 1–12). The second part (ii. 1–12) is eschatological, and warns the readers against supposing 'that the day of the Lord is now present' (so R.V.; A.V. has 'at hand'). On the contrary, it will not be except the falling away ('the apostasy') come first, and the man of sin be revealed, the son of perdition, he that opposeth and exalteth himself against all that is called God or that is worshipped; so that he sitteth in the temple of God, setting himself forth as God. This mystery of lawlessness is already at work, only there is one that restraineth. When this restraining presence or influence shall be taken out of the way, then shall be revealed the lawless one, whom the Lord Jesus shall slay with the breath of His mouth, and bring to nought by the manifestation of His coming. The coming of the lawless one is to be according to the working of Satan with all power and signs and lying wonders and with all deceit of unrighteousness. The third and concluding part of the epistle (ii. 13–iii. 18) is of a practical nature, and substantially repeats the exhortations of 1 Thessalonians. The genuineness of this epistle was first doubted by J. E. Ch. Schmidt (1801); the volume of opinion in this sense has steadily increased since then, and is now very great. The argument turns chiefly upon ii. 1–12; in the rest of the epistle there is nothing that can be called un-Pauline, and the question of its absolute genuineness apart from these verses is comparatively unimportant. The difficulty about the eschatological passage in question is, in a word, that no traces of such a view occur in any other writing of the apostle Paul, whether prior or subsequent to the supposed date of 2 Thessalonians. Indeed the difficulty of reconciling it with the ordinary Pauline view is suggested by the passage itself: 'be not quickly shaken . . . by epistle as from us, as that the day of the Lord is close at hand' (*enestēke*); but this is practically the suggestion of 1 Thessalonians. It is impossible to fix with any accuracy the date of the verses in question. They are conceived in the spirit of a great deal of the apocalyptic that was current in Jewish (and in a less degree in Christian) circles during the last two centuries of Judaism; and, with certain modifications, the ideas admitted of application to a considerable variety of circumstances, now to those of the Jews under Caligula, now to those of the Jews or Christians under Nero. On the hypothesis of its genuineness, in whole or in part, 2 Thessalonians must have been written shortly after 1 Thessalonians and before the apostle's sojourn of eighteen months in Corinth had come to an end. Apart indeed from ii. 1–12, 2 Thessalonians may conceivably have been written before 1 Thessalonians, a view which has been argued for by Grotius amongst others.

The literature of the subject is the same as for 1 Thess. Add Weizsacker, *Apost. Zeitalter;* Pfleiderer, *Urchristenthum;* and the suggestive incidental discussion in Spitta, *Offenbarung des Johannes* (1889).

Thessaloni'ca. See SALONICA.

Thessaly, the largest division of ancient Greece, lay south of Macedonia and east of Epirus, being separated from the latter by Mount Pindus, and from the former by the Cambunian Mountains, and the Maliac Gulf and Mount Œta bounding it on the S. It is a vast plain shut in on every side by mountains; on the N. and W. by those already named, on the S. by Mount Othrys, and on the E. by Mounts Pelion and Ossa, the only opening being the Vale of Tempe in the north-east, between Ossa and Olympus. This plain is drained chiefly by the river Peneus (now *Salambria*) and its tributaries, and is the most fertile in all Greece. Thessaly was originally inhabited by so-called Pelasgians, who, however, were either expelled or reduced to slavery by Dorian immigrants from the more rugged region of Epirus about 1000 B.C. (see GREECE, Vol. V. p. 386). The Penestæ, descendants of the old inhabitants, held a position analogous to that of the Helots (q.v.) in Sparta. There were four districts—Hestiæotis, Pelasgiotis, Thessaliotis, and Phthiotis; Magnesia on the coast being a minor division. The government appears to have been oligarchical in the separate cities—of which Pharsalus, Larissa, Heracleum, and Pheræ were the chief—the principal power being in the hands of the two great families of the Alenads and Scopads. About 374 B.C. Jason, tyrant of Pheræ, was elected Tagus (chief-magistrate) of all Thessaly. The rule of Jason's successors became so unbearable that aid was sought from Philip of Macedon, who in 344 subjected the country to Macedonia. Thessaly remained subject to the Macedonian kings till the victory of Cynoscephalæ, in 197 B.C., brought it under the protection of Rome. Under the emperors Thessaly was united with Macedonia, but after Constantine it was a separate province. In 1204 A.D., with other portions of the eastern empire, it came under the dominion of the Venetians, and in 1355 was taken by the Turks. The restoration to Greece of Thessaly south of the Salambria was recommended by the Berlin Congress in 1878; and subsequently various modifications of the Greco-Turkish frontiers were proposed, the Greeks endeavouring to secure the cession of the whole of Thessaly. War between Greece and Turkey seemed imminent; but in 1881 Turkey agreed to cede, and Greece to accept, Thessaly south of the watershed of the Salambria (the ancient Peneus), the most fertile section of the province. The Greek invasion of the northern part of Thessaly in April 1897 ended, after a short stand, in a disastrous retreat, and the Turks occupied Larissa.

Thetford, a market-town on the border of Norfolk and Suffolk, at the Thet's confluence with the Little Ouse, 31 miles SW. of Norwich and 12 N. of Bury St Edmunds. Doubtfully identified with the Roman Sitomagus, it was the capital of Saxon East Anglia, the seat from 1070 of a bishopric, transferred to Norwich in 1094; suffered much from the Danes between 870 and 1010; and in Edward III.'s time had eight monasteries and twenty churches (now only three). The steep Castle Hill, 100 feet high and 260 yards in circumference, is one of the largest earthworks in the kingdom; and there are considerable remains of Bigod's Cluniac priory (1104). The grammar-school (1566) was rebuilt in 1879. The industries include brewing, tanning, and the manufacture of farming machinery; and there is some trade by barges on the Ouse. 'Honest' Tom Martin, the antiquary, and Tom Paine were natives. Incorporated in 1573, Thetford returned two members till 1867–68. Pop. (1851) 4075; (1891) 4247. See works by Martin (1779) and A. L. Hunt (1870).

Thetis, daughter of Nereus and Doris, was married against her will by the gods to Peleus, and became the mother of Achilles. She dwelt in the depths of the sea with her father, and had, like Proteus, the power of changing her shape.

Theuriet, ANDRÉ, French poet and romancer, was born in 1833 at Marly le Roi, near Paris, studied law in Paris, and received in 1857 a place in the office of the minister of finance. That same year he published a striking poem in the *Revue des Deux Mondes*, which was followed only in 1867 by *Le Chemin des Bois*, a volume of poems full of the charm of woodland. Later poems were the

so-called epic *Les Paysans de l'Argonne, 1792* (1871), and *Le Bleu et le Noir* (1872), styled a poem of real life. But Theuriet is best known by his novels, which are ever touched with melancholy and sometimes recall in their feeling for the poetic sides of nature the subtler touch of George Sand. They include *Mademoiselle Guignon* (1874), *Le Mariage de Gérard*, *Une Ondine* (1875), *La Fortune d'Angèle* (1876), *Raymonde* (1877), *Le Filleul d'un Marquis* (1878), *Le Fils Maugars* (1879), *Le Sang des Finoel* (1879), *Tante Aurélie* (1884), *L'Amoureux de la Préfète* (1888), *Nos Enfants* (1892), *La Chanoinesse* (1893), *Flavie* (1895). Theuriet was admitted to the Academy in 1896. See the study by Besson (1890).

Thibet. See TIBET.

Thick-knee (*Oedicnemus*), a genus of birds of the family Otididæ. In haunts and habits they closely resemble the Bustards (q.v.), but they differ from them chiefly in having the bill longer, the wings more pointed, and the tarsus finely reticulated before and behind. They are partly nocturnal; their flight is strong and rapid, but somewhat laboured; their call-notes are loud and discordant. Thick-knees run with great speed. They are generally very shy, and are found chiefly in desert places. There are eleven species, widely distributed, being absent only from North America. Only one species is European. It occurs in Britain, and is known as the Common Thick-knee *O. crepitans* or *scolopax*), and also as the Thick-kneed Plover, Thick-kneed Bustard, Great Plover, Norfolk Plover, and Stone Curlew. It is found in many parts of England on chalk downs and open heaths. A few specimens have been found in Ireland, and it has been recorded from Scotland. Worms, slugs, insects, frogs, and field-mice constitute its food. They build no nest, but choose a depression in the ground in which to lay their eggs, generally two in number. One species is Australian.

Thielt, a town of Belgium, 18 miles SE. of Bruges by rail, with manufactures of lace, linens, and oil. Pop. 9850.

Thierry, JACQUES NICOLAS AUGUSTIN, French historian, born at Blois, 10th May 1795. His father, who became town-librarian, was his first instructor; while yet young he obtained a 'bourse' at the college of his native town, and in 1811 entered the *École Normale*. In 1814 he completed his courses and joined the ranks of the Parisian Liberals. Soon after appeared his first book, entitled *De la Réorganisation de la Société Européenne*. In this and subsequent treatises he considered the notion of one government for the whole of Europe without the destruction of national characteristics. These works were inspired by Saint-Simon (q.v.), whose secretary Thierry became, and with whom he lived for three years. In 1817, however, he and Saint-Simon no longer agreed; and Thierry joined Comte, who had not then fallen under the influence of Saint-Simon (see COMTE). Jointly with Dunoyer Thierry aided for three years in the *Censeur Européen*, where he found plenty of practice as a student and exponent of history. In 1820, however, he contributed his 'Letters on the History of France' to the *Courrier Français*, and showed a new influence acting on his own mind, and destined in turn to act largely on his future readers; bringing history, in fact, to practical application. Thierry dwelt on the principle of race, and attributed the establishment of the feudal system (with the evils which he ascribed to it) to the subjugation of western Europe by the Germans and Scandinavians. In 1825 he published his masterpiece, the *Conquest of England*, followed in 1827 by a series of 'Letters on History;' but the labour cost him his eyesight. In 1828 he went to the south of France for the benefit of his health; and here he met Julie de Quérengal, a lady of considerable literary accomplishment, whom he married. In 1835 he became librarian at the Palais Royal, and published his *Dix Ans d'Études*, the introduction to which is famed for its eloquence. In 1840 he received the 'Gobert' prize, which the Academy made perpetual in his favour. His last work was on the *Tiers État*, published in 1853; and three years later his laborious life was closed by paralysis, 22d May 1856. He may be called the father of romantic history, and a disciple of the school of Sir Walter Scott, whom he regarded as the 'great master of historical divination;' he also described himself as indebted for inspiration to Chateaubriand's *Martyrs*. After Michelet he is the greatest artist of his class. See a monograph by Aubineau (2d ed. 1879).—A younger brother, AMÉDÉE SIMON DOMINIQUE THIERRY (1797–1873), was likewise a Liberal and a historian, his chief works histories of Gaul and of Attila.

Thiers, a manufacturing town in the French dept. of Puy-de-Dôme, on the right bank of the Durole, 23 miles ENE. of Clermont by rail. Its manufactures of cutlery, paper, and playing-cards gave to the town a certain importance in the 17th century. Pop. (1891) 11,993.

Thiers, LOUIS ADOLPHE, French historian, politician, and patriot, was born at Marseilles on April 16, 1797. His father, who seems to have belonged to a family in decayed circumstances, was a locksmith. Through the influence of his mother, who was a Chénier, he received a good education, first at the Lycée in his native city, and subsequently (1815) at Aix, whither he was sent to study law. At Aix he made the acquaintance of Mignet, cultivated literature rather than the law, and won a prize for a dissertation on Vauvenargues. Called to the bar at the age of twenty-three, he set off for Paris in the company of Mignet. His prospects did not seem brilliant, and his almost ludicrously squat figure and plain face were not recommendations to Parisian society. His industry and belief in himself were, however, unbounded, and an introduction to Lafitte, of the *Constitutionnel*, then the leading organ of the French Liberals, gave him the chance of showing his capacity as a public writer. His articles in the *Constitutionnel*, chiefly on political and literary subjects, gained him the entry into the most influential *salons* of the opposition. At this time he made the acquaintance of Talleyrand, Casimir Périer, the Comte de Flahault, and Baron Louis the financier. Meanwhile he was rapidly—indeed too rapidly—preparing his *Histoire de la Révolution Française*. The first two volumes—there were ten in all—appeared in 1823. This work, although it has been demonstrated to be very untrustworthy and inaccurate, more especially in its estimates of persons, gave its author a prominent place among French politicians and men of letters. About this time, too, the gift by his admirer, Cotta, the German publisher, of a share in the *Constitutionnel* raised him to comparative affluence. In January 1830 he, along with Armand Carrel, Mignet, and other friends, started the *National*, and in its columns waged relentless war on the Polignac administration. The ministry met the opposition it had provoked by the Ordonnances of July. Among the other repressive measures that were taken was the sending of a commissary of police to the office of the *National* interdicting its publication. Its

conductors, with Thiers at their head, defied the ministry, and the result was the revolution which drove Charles X. into exile.

Thiers now entered on an active career as a politician. He was elected deputy for the town of Aix, and was appointed Secretary-general to the minister of Finance. His first appearance in the Chamber of Deputies gave no promise of his subsequent distinction. His diminutive person, his small face, encumbered with a pair of huge spectacles, and his whole exterior presenting something of the ludicrous, the new deputy, full of the impassioned eloquence of the revolutionary orators, attempted to impart the thrilling emotions affected by Mirabeau. The attempt provoked derision; but soon subsiding into the oratory natural to him —simple, easy, rapid, anecdotic—he became one of the most formidable of parliamentary speakers. Almost from the moment of his entrance into public life he and Guizot stood forth in opposition to each other as the champions of Radicalism and Conservatism respectively. But he was a staunch Monarchist, and for a time a favourite with Louis-Philippe. In 1832 he accepted the post of minister of the Interior under Soult, exchanging it subsequently for the ministry of Commerce and Public Affairs, and that in turn for the Foreign Office. He was universally regarded as a stronger man than any of his chiefs during this period; but his public and private actions alike were always marked by a certain fussy quarrelsomeness which prevented him from being ever accounted a statesman of the first rank. The 'spirited foreign policy,' calculated above all things to precipitate a quarrel between France and Great Britain, of which for many years he was the chief advocate, is now allowed to have been a great, and might have been a fatal, mistake. In 1836 he became President of the Council, but in August of the same year he resigned office and became the leader of the opposition. In 1840 he was again summoned to office as President of the Council and Foreign Minister. In a few months he was a terror to the peace of Europe. He refused Lord Palmerston's invitation to enter into an alliance with Britain, Austria, and Prussia, for the preservation of the integrity of the Ottoman Empire, from a sympathy with the principles which dictated the first Napoleon's invasion of Egypt and Syria, and a desire to accomplish by diplomacy with Mehemet Ali what Bonaparte had endeavoured to effect by force of arms—the supremacy of France in these regions. He talked menacingly of setting aside the treaties of 1815 and of extending the French frontier to the Rhine, and is said to have actually spent £8,000,000 on military and naval demonstrations. On his application to the British government, Napoleon's remains were removed from St Helena and brought to the Invalides, 15th Dec. 1840. Meanwhile Thiers, unable to agree with the king, had resigned (29th Oct.), and for years took little part in public affairs. He now returned to the study of French history. The first volume of his *Histoire du Consulat et de l'Empire* appeared in 1845; it was not completed till 1860. This, the most ambitious of all Thiers's literary enterprises, must be considered a large rather than a great work. It is a monument to its author's industry in reading, and rises here and there to rhetorical brilliance. But that it is inaccurate and unfair has been admitted even by French critics. Thiers greatly overrated Napoleon, and probably to his own hurt.

Thiers was not one of the promoters of the revolution which in 1848 drove Louis-Philippe from the throne. On the contrary, he would, as prime-minister summoned at the eleventh hour, have prevented it if he could. He accepted its consequences in the form of the Republic. He voted for the election of Prince Louis Napoleon as its president. This action brought him much vituperation and ridicule from former political friends. But whatever may have been the motive that inspired it, it certainly did not help him at the time of the *coup d'état* of 1851; he was arrested, imprisoned in Mazas, and banished. Next year, however, he was allowed to return from Switzerland to France. For eight years he was occupied with his *History of the Consulate and Empire*. He re-entered the Chamber in 1863, having been elected Liberal deputy for the department of the Seine in opposition to the Imperialist candidate. Till the fall of the Second Empire he was regarded as the ablest and most formidable of its more moderate and parliamentary opponents. His speeches in the years between 1863 and 1870 were filled with taunts of the Empire on account of the loss of prestige which had marked its history; and these must not be left out of account when blame has to be apportioned among the authors of the war of 1870, although he opposed it when declared by the Ollivier ministry, and predicted defeat.

The collapse of the Second Empire, however, enabled Thiers to play the greatest of all his parts, that of 'liberator of the territory.' He declined, after Sedan, to become a member of the Government of National Defence; but he voluntarily undertook diplomatic journeys to Great Britain, Russia, Austria, and Italy, on behalf of France—a self-imposed mission in which he was unsuccessful, but by which he obtained the gratitude of his countrymen. He was largely instrumental in securing for his country that armistice which permitted the holding of a national assembly with a view to the negotiation of a peace. Twenty constituencies chose him as their deputy. Electing to sit for Paris, he was made head of the provisional government. He had great difficulty in persuading his colleagues of the Assembly, and his countrymen generally, to agree to peace on terms that were practically dictated by Germany. But he succeeded; peace was voted March 1, 1871. No sooner had he accomplished this task than he was face to face with the sanguinary madness of the Commune. But this difficulty also he set himself to surmount with characteristic energy, and succeeded. When the seat of government was once more removed from Versailles to Paris, Thiers was formally elected (August 30) president of the French Republic. He held office only till 1873, but during this brief period he was probably of greater service to his country than at any previous time in his life. He was mainly instrumental in securing the withdrawal of the Germans from France, and the payment of the war indemnity, and in placing both the army and the civil service on a more satisfactory footing. But in course of time the gratitude of the country exhausted itself, and Thiers, who was old-fashioned in many of his opinions, and as opinionative as he was old-fashioned, did not make any new friends. He was specially detested by the Extreme Left, whose chief, Gambetta, he styled a *fou furieux*. As a result, a coalition of Reactionaries and Radicals was formed expressly, as it seemed, to harass him, and even in the beginning of 1872 he tendered his resignation. It was not accepted; and his opponents for a time suspended their intrigues. They were revived, however, in 1873, and resolved themselves into a resolute effort to limit the powers of the president. This Thiers stoutly resisted. He made an appeal to the country, but this course did not increase the strength of his following. Finally what he interpreted as a vote of no confidence was carried (May 24) by a majority of sixteen. He

resigned, and his place was taken by Marshal MacMahon. He lived four years longer, and never ceased to take an interest in politics. In 1877 he took an active part in bringing about the fall of the ministry presided over by the Duc de Broglie. He now leaned to the side of the Left, and was reconciled to Gambetta, and he might once again have played a prominent part in politics had he not died of apoplexy on September 3, 1877, at St Germain-en-Laye. He has not left behind him the memory either of a very great statesman or of a very great historian. But he was a man of indomitable courage, and his patriotism, if narrow and marred with Chauvinism, was deep and genuine. He was perhaps the most successful of the large class of journalist-politicians that France has produced, and that he was at least a personal power in literature was evidenced by the great influence which he wielded in the Academy, of which he became a member in 1834.

An authoritative biography of Thiers has yet to be published. Many editions of his chief works have been issued, his parliamentary speeches fill a score of volumes, and the studies of him are innumerable. Those of M. Jules Simon and M. Charles de Mazade especially deserve attention, and M. Paul de Remusat's *A. Thiers*, translated (1892) by Melville B. Anderson, discusses its subject carefully from the literary point of view.

Thionville (Ger. *Diedenhofen*), a fortified town of Lorraine, 18 miles N. of Metz by rail, an important railway centre; pop. (including garrison) 7155. Taken by Condé in 1643, it fell with Lorraine to France, but was besieged, bombarded, and taken by the Germans, 9th–25th November 1870.

Third, in Music. See INTERVAL.

Thirlage, an old Servitude (q.v.), or rather service, enjoyed by the proprietor of a mill over the neighbouring lands 'thirled' to it, whereby the possessors (and tenants) of the lands were bound to have their grain ground at that mill, and to pay as 'multure' or duty a certain proportion of the grain ground, varying from a thirtieth to a twelfth of the corn ground. The possessors of the astricted lands were called *suckeners;* the multure paid by those who were not bound, but used the mill, was out-sucken multure. Since 1799 this class of local burdens has almost entirely disappeared by commutation, voluntary renunciation, or private agreement. Such a servitude or easement was rare in England.

Thirlmere, a narrow sheet of water in the heart of the Lake District (q.v.), lying 533 feet above sea-level, and 3 miles long by ¼ mile wide, between Derwentwater and Grasmere. Since 1894 it serves as a water-supply for Manchester (q.v.); see also AQUEDUCT.

Thirlwall, CONNOP, a great English bishop and historian of Greece, was born, of good Northumbrian stock, at Stepney in Middlesex, January 11, 1797. He was a child of almost unexampled precocity, learned Latin at three, read Greek at four, and at eleven published *Primitiæ* (1809), a volume of poems and sermons which in later years he did his best to suppress. He next went to Charterhouse, where Grote, Julius Hare, and Henry Havelock were among his schoolfellows; entered Trinity College, Cambridge, in October 1814, and in the February of the following year carried off the Craven scholarship, which only Porson and Professor Kennedy have done as freshmen. That same year he gained the Bell scholarship; in 1818 he graduated as 22d senior optime—there being yet no classical tripos—but his real rank was better marked by the first Chancellor's classical medal. In October he was elected to a Trinity fellowship, and next spent about a year on the Continent, making fast friendship with Bunsen at Rome. He entered as a law-student at Lincoln's Inn in February 1820, and soon after joined the famous debating society that included Mill, Macaulay, Charles Austin, Romilly, the two Bulwers, Samuel Wilberforce, and later Maurice and John Sterling. He was called to the bar in 1825, but the natural bent of his mind prevailed, and in 1827 he took orders.

Already in 1825 he had translated Schleiermacher's *Essay on St Luke* and written an introduction—a remarkable performance for a barrister. His return to Cambridge was marked by the commencement, in conjunction with his dear friend Julius Hare, of a translation of Niebuhr's *History of Rome* (vol. i. 1828; ii. 1832). Their famous *Philological Museum* (1831–33) saw only six numbers, but contained some remarkable papers, among them Thirlwall's 'On the Irony of Sophocles.' Besides all this he took a full share of college and clerical work—the latter at Over, 8 miles from Cambridge. In 1834 he signed the petition in favour of the admission of dissenters to academical degrees, and in May put forth a weighty pamphlet in defence of the measure. Thirlwall pointed out with characteristic plainness the perfunctory nature of the religious education that existed, and expressed the belief that compulsory chapel services were 'a hindrance and not a help to the religious life.' The Master of the College, Dr Chr. Wordsworth, now called on him to resign the assistant-tutorship, which he did at once, though under protest. Almost immediately he was presented by Lord Brougham to the quiet Yorkshire living of Kirby-Underdale. Here he wrote for *Lardner's Cyclopædia* his *History of Greece* (8 vols. 1835–47; improved ed. 1847–52). In 1840 Lord Melbourne raised Thirlwall to the see of St David's, and within six months thereafter he preached in perfect Welsh. For thirty-four years he laboured with the utmost diligence in his diocese, building churches, parsonages, and schools, and augmenting poor livings (to the extent of £30,000 from his own pocket); and, though he wrote no great work, his eleven Charges remain an enduring monument of breadth of view and soundness of judgment in reference to all ecclesiastical controversies of one generation. His Primary Charge (1840) was a catholic-spirited apology for the Tractarian party then being vehemently *charged* against by almost every bishop and archdeacon in England. In later days (Charges of 1866 and 1872) he modified greatly his approval of the spirit that animated the new party, but his grave warnings and protests against their Romanising tendencies rise characteristically into a serenely judicial region far above the heated and vulgar atmosphere of polemical debate. Thirlwall joined in the encyclical letter censuring *Essays and Reviews*, but was one of the four bishops who refused to inhibit Bishop Colenso. He supported the Maynooth grant, the admission of Jews to parliament, and alone amongst the bishops voted for the disestablishment of the Irish Church, although he would have preferred to see a measure of concurrent endowment. He was appointed chairman of the Old Testament Revision Committee, and resigned his see in May 1874, retiring to Bath, where he died, July 27, 1875.

Thirlwall's massive understanding, vast learning, and fundamental breadth and fairness of mind were a combination of enormous value to the Church of England; and no words of epitaph could have been found better than those inscribed on the granite slab over his grave in Westminster Abbey, where he sleeps side by side with his brother-historian Grote: 'Cor sapiens et intelligens ad discernendum judicium.' He never married, but lived throughout life in the midst of his nephews

and their children, and his love for cats rivalled Southey's. And few men have left a more pleasing though unconscious monument of noble character than the beautiful series of letters to a young lady —the *Letters to a Friend*, edited by Dean Stanley in 1881.

His *Remains, Literary and Theological*, fill three volumes (vols. i. and ii. Charges, 1877; vol. iii. Essays, Speeches, Sermons, 1878), edited by Dean (Bishop) Perowne. The *Letters, Literary and Theological*, were edited by Dean Perowne and the Rev. Lewis Stokes in 1881. See the *Edinburgh Review* for April 1876.

Thirsk, a town in the North Riding of Yorkshire, in the Vale of Mowbray, on the Cod Beck, an affluent of the Swale, 23 miles NNW. of York. It has a fine Perpendicular church, and carries on manufactures of agricultural implements and saddlery. Thirsk returned two members to parliament till 1832, and then one till 1885. Pop. 3164. See W. Grainge, *The Vale of Mowbray* (1859).

Thirst is a well-known sensation, resulting from a peculiar state of the system, but especially of the mucous membrane of the fauces, usually caused by an insufficient supply of liquid. In cases of extreme thirst there is a peculiar sense of clamminess in the mouth and pharynx, which, with the other disagreeable feelings, is almost immediately relieved by the introduction of liquid into the stomach, where it is absorbed by the veins. That the thirst is relieved by the absorption of the fluid, and not by its action as it passes over the mucous membrane, which seems to suffer most, is proved by the facts (1) that injection of liquids into the stomach through a tube (in cases of wounded œsophagus), and (2) the injection of thin fluids, as water, into the blood, remove the sensation of thirst. An excessive thirst is often an important morbid symptom. It may arise from two very opposite conditions—one a condition of excitement, and the other of depression. Whenever the blood is in a state requiring dilution, and is too stimulating, as in fevers and inflammations, there is thirst; and, again, in cases of excessive secretion and exhaustion, as for example in cholera and in the two forms of diabetes, there is great thirst, which sometimes also attends the lowest stages of prostration in malignant diseases. When there is a great loss of the watery portion of the blood by profuse perspiration, caused not by disease, but by hard bodily exercise in a hot atmosphere, as in the case of coal-whippers, mowers and reapers, &c., there is always great thirst, and from two to four gallons of beer or cider a day may, in these cases, be taken with apparent impunity. Cold tea, without milk or sugar, is the most satisfying drink under these circumstances. Independently of disease, great thirst may be induced by the use of salted meat or fish, highly-peppered curries, and other stimulating dishes, the ingestion of malt liquors drugged with salt and more pernicious matters, or of gin strengthened with sulphuric acid, &c.

Thirty-nine Articles. See ARTICLES.

Thirty Years' War, a war or rather an uninterrupted succession of wars (1618–48) in Germany, in which Austria, most of the Catholic princes of Germany, and Spain were engaged on the one side throughout, but against different antagonists. This long-continued strife had its origin in the quarrels between the Catholics and Protestants of Germany, and few wars in modern times have caused more slaughter, misery, ruin, and demoralisation. The severe measures taken by the emperor, the head of the Catholic party, against the Protestants' religion led also to restrictions on their civil rights; and it was to protect their political as well as their religious liberties that the Protestants formed a union in 1608. The rival union of the Catholic powers followed in 1609. (1) *Bohemian War* (1618–20). The withdrawal of concessions to the Protestants of Bohemia by the Emperor Rudolf II. led to an insurrection in Prague and the election of Frederick V., the Elector Palatine, as king of Bohemia (1619); and Count Thurn repeatedly routed the imperial troops. But on 8th November 1620 a well-appointed army of 30,000, under Duke Maximilian of Bavaria, totally routed Frederick's motley array at Weissenberg near Prague, while an army of Spaniards under Spinola ravaged the Lower Palatinate. The Bohemians were now subjected to the most frightful tyranny and persecution.

(2) *War of the Palatinate* (1621–24). But the indomitable pertinacity and excellent leadership of Count Mansfeld and Christian of Brunswick, two famous partisan leaders, who ravaged the territories of the Catholic league, did much to equalise the success of the antagonistic parties. Here the war might have ended; but the fearful tyranny of Ferdinand over all the Protestants in his dominions (Hungary excepted) drove them to despair, and the war advanced to its third phase.

(3) *Danish-Saxon War* (1624–30). Christian IV. of Denmark, smarting under some injuries inflicted on him by the emperor, and aided by a British subsidy, came to the aid of his German co-religionists in 1624, and, being joined by Mansfeld and Christian of Brunswick, advanced into Lower Saxony. But when, by the aid of Wallenstein, a powerful army had been obtained, and the leaguers under Tilly, in co-operation with it, had marched northwards, the rout of the Danes by Tilly at Lutter, and of Mansfeld by Wallenstein at Dessau, again prostrated the Protestants' hopes in the dust; yet a gleam of comfort was obtained from the victorious raid of Mansfeld through Silesia, Moravia, and Hungary. The combined imperialists and leaguers meantime had overrun North Germany and continental Denmark, and ultimately compelled King Christian to conclude the humiliating peace of Lübeck.

(4) *Swedish-German War* (1630–36). Ferdinand, not content with a still more rigorous treatment of the Protestants, and the promulgation of the *Restitution Edict*, which seriously offended even the Catholics, stirred up Poland against Sweden, and insulted Gustavus Adolphus; and the war entered its fourth stage on the landing of the Swedes at Usedom (June 1630), and their conquest of Pomerania and Mecklenburg. Gustavus induced the Elector of Brandenburg to aid him; and though unable to save Magdeburg, he marched to join the Saxons, completely routed Tilly at Breitenfeld (1631), victoriously traversed the Main and Rhine valleys, again routed Tilly on the Lech (1632), and entered Munich. By the judicious strategy of Wallenstein he was however compelled to retire on Saxony, where he gained the great victory of Lützen (1632); but his death there, depriving the Protestants of the only man who could force the confederate powers to preserve unity of action, was a severe blow to their cause; though the genius and indefatigable zeal of his chancellor, Oxenstierna, and the brilliant talents of the Swedish generals, preserved the advantages they had gained, till the crushing defeat of Bernard of Weimar at Nordlingen (1634) again restored to the emperor a preponderating influence in Germany. Saxony now made peace at Prague (1635).

(5) *Swedish-French War* (1636–48). Final success now appeared to demand only one more strenuous effort on the part of Austria; but Oxenstierna, resolved to preserve to Sweden her German acquisitions, propitiated Richelieu (q.v.) by resigning to him the direction of the war; and the

conflict advanced into its final and most extended phase. The emperor, allied with the Lutherans, was now also assailed through his ally, Spain, who was attacked on her own frontier, in the Netherlands, and in Italy; Bernard of Weimar, fighting independently, opposed the leaguers; while the Swedes, under Baner, held North Germany, and by frequent flying marches into Silesia and Bohemia distracted their opponents, and prevented them, after their successes over Duke Bernard, from proceeding with the invasion of France. The great victory of Baner over the Austrians and Saxons at Wittstock (1636) restored to Sweden the victor's wreath; and from this time, especially under Torstensohn and Konigsmark, the Swedes were always successful, adding a second victory of Breitenfeld (1642) and one at Jankau (1645) to their already long list of successes, and carrying devastation and ruin even to the gates of Vienna. On the Rhine the leaguers at first had great success; but after the Spanish power had been thoroughly broken in the Netherlands by Condé the French were reinforced on the Rhine, and under Condé and Turenne rolled back the leaguers through the Palatinate and Bavaria, and revenged at Nordlingen (3d August 1645) the former defeat of the Swedes. The emperor was now deserted by all his allies except the Duke of Bavaria, whose territories were already mostly in the hands of Turenne and Wrangel; and a combined invasion of Austria from the west and north was on the point of being executed when, after seven years of diplomatic shuffling, the Peace of Westphalia (q.v.) put an end to this terrible struggle.

See the articles on the principal leaders in the struggle, especially Gustavus Adolphus and Wallenstein, and works there cited; Professor A. W. Ward's *Thirty Years' War* (1869), S. R. Gardiner's *Thirty Years' War* (1874); and German works by Schiller (Eng. trans. 1846), Soltl, Barthold, Gindely (Eng. trans. 2 vols. 1885), &c.

Thisbe. See PYRAMUS.

Thistle (*Carduus*), a genus of plants of the natural order Compositæ, sub-order Cynarocephalæ, with spinous leaves, imbricated involucres, and heads of flowers, consisting of tubular hermaphrodite florets alone, very rarely diœcious, stamens free, pappus deciduous, the receptacle having chaffy bristles. The flowers are sometimes large, generally purple, rarely white or yellowish. Recent botanists have divided this genus into two genera —the True Thistle (Carduus), in which the pappus is composed of simple hairs, and the Plume Thistle (Cirsium or Cnicus), in which the pappus is feathery. The species of both genera are numerous, and are found in most of the temperate and cold parts of the northern hemisphere, annual, biennial, and perennial herbaceous plants of considerable size. The Milk Thistle (*Carduus marianus*), a biennial, native of Britain and other parts of Europe, attains a height of 4 to 6 feet, and is remarkable for the milky veins of its large waved leaves. Its blanched leaves are used in winter salads; they may also be used as a boiled vegetable, along with the young stalks, and the root is used as salsify. The plant used to be cultivated. The creeping Plume Thistle (*Cirsium arvense*, or *Cnicus arvensis*), a species about 1 to 3 feet high, with creeping roots, pinnatifid leaves and numerous diœcious flowers, is a very troublesome weed in fields, very common in Britain, and now too common, not only in Europe, where it is indigenous, but in America (where it is called Canada Thistle) and other countries to which it has found its way; in Australia the thistle has become a serious plague. *Cirsium lanceolatum* (the Spear or Bur Thistle) and *C. palustre*, both common British plants, are also troublesome weeds. *Cirsium oleraceum* is a native of the north of Europe, but not of Britain. The Blessed Thistle (*Carduus benedictus* of the pharmacopœias, *Cnicus benedictus* or *Cirsium benedictum* of modern botanists) is a native of the Levant and of Persia, resembling in appearance a Centaurea, with yellow flowers enveloped in leaves, and abounding in a gossamer-like down; it is a powerful laxative-tonic medicine. The Cotton Thistle (Onopordon) is a distinct genus, known by its receptacles being destitute of bristles, and coarsely and deeply honeycombed. The Common Cotton Thistle (*O. acanthium*), a native of Europe, and found in England, but rarely wild in Scotland—if, indeed, it is a true native of that country—is nevertheless very generally called by gardeners and others the Scotch Thistle. The national emblem of Scotland is not, in all probability, any one species of thistle in particular, as botanically distinguished; though the Stemless Thistle (*Cnicus acaulis*, or *Cirsium*

Stemless Thistle (*Cnicus acaulis*).

acaule) is in many districts of Scotland so designated. The cotton thistle has large elliptic leaves, and a broadly-winged stem. The young fleshy root and stem are boiled and eaten. Plants of the genus Silybum, and of the genus Echinops, which belongs to a very different section of the Compositæ, are often to be seen in flower-gardens, where they are known as Thistles. The name is also, generally with some addition, very often bestowed upon many plants which have little resemblance to any of these, except in their spinous character. *Centaurea calcitrapa* is the Star Thistle (see CENTAUREA); the Jersey Thistle is *Centaurea isnardi;* the Fuller's Thistle is Teasel (q.v.); Torch Thistle, *Melocactus;* and the Golden Thistle, *Protea scolymus.* And see SOW-THISTLE, SAFFLOWER, BURDOCK, &c. Among American species are the Swamp Thistle (*Cnicus muticus*), the Tall Thistle (*C. altissimus*), and the Mexican Thistle (*Cnicus* (*Erythrolæna*) *conspicuus*). The Carline Thistle has a separate article.

Thistle, ORDER OF THE, called also the Order of St Andrew, is of no very ancient date. The earliest known mention of the thistle as the national badge of Scotland is in the inventory of the effects of James III., who probably adopted it as an appropriate illustration of the royal motto, *In defence.* Thistles occur on the coins of James IV., James V., Mary, and James VI.; and on those of the last they are for the first time accompanied by the motto, *Nemo me impune lacesset.* A collar of thistles appears on the gold bonnet-pieces of James V. of 1539; and the royal ensigns, as depicted in Sir David Lindsay's armorial register of 1542, are surrounded by a collar formed entirely of gold thistles, with an oval badge attached. This collar, however, was a mere device until the institution, or, as it is generally but inaccurately called, the revival of the order of the

Thistle by James VII. (II. of England), which took place on May 29, 1687. Statutes were issued, and eight knights nominated by James; but the patent for the institution of the order never passed the Great Seal. After falling entirely into abeyance during the reign of William and Mary, the order

Star, Collar, and St Andrew of the Order of the Thistle.

was revived by Queen Anne, December 31, 1703, and the statutes then issued still, with some changes, govern the order. By them the word '*lacesset*' in the motto was altered to '*lacessit*.' The number of knights was originally fixed at twelve, a number raised by George IV. in 1827 to sixteen, at which it now stands. Provision was made for a Chancellor of the Order, but none has ever been appointed; the other officers of the order are the Dean, the Secretary, Lord Lyon King-of-arms, and the Usher of the Green Rod.

Thistlewood Conspiracy. See CATO STREET CONSPIRACY.

Tholen, an island in the Netherlands, constituting part of the province of Zeeland. The town of Tholen has a pop. of 2758.

Tholuck, FRIEDRICH AUGUST, theologian and preacher, was born at Breslau, 30th March 1799, and studied at Breslau and Berlin. Oriental languages first attracted him, and he somewhat paradoxically maintained the superiority of Mohammedanism to Christianity. The influence of Neander and of a pious nobleman, Von Kottwitz (a Moravian Brother), produced a marked change in his feelings; and by 1825 he was a champion of that fervid but catholic evangelical Christianity to which all his later life, lectures, sermons, and published books were a testimony. In 1824 he was appointed extra-ordinary professor of Oriental Languages at Berlin, as successor to De Wette; in 1826 he was called to Halle as ordinary professor of Theology; and there, save for a year and a half (1827–28) spent by him as chaplain to the Prussian embassy at Rome, where Bunsen was ambassador, he spent the rest of his lovable and laborious life. At first he had difficulties in Halle, the tone of the university being strongly Rationalist, and his colleagues, Gesenius and Wegscheider, were distinctly hostile to Tholuck's pietism; but ultimately he profoundly influenced the whole university in a direction favourable to devoutness, if not to old-fashioned orthodoxy. And his personal relations with the students instilled evangelical fervour into many successive generations of theological students from all parts of Germany, from Britain, and from America. Theologically he was not a strait-laced orthodoxist; he made very considerable concessions to criticism, and his line of thought was highly eclectic, containing elements from Pietism and Moravianism, from Hegel and Schleiermacher, but more still from the pectoral theology of Neander. As a writer and commentator he was rather suggestive and pregnant than profound or exhaustive. Of German theologians he is probably the one who has been most heartily accepted by English-speaking Protestants. He was a powerful preacher, and continued to lecture in spite of advancing years and enfeebled health till shortly before his death, 10th June 1877.

His earliest important work is *Die Wahre Weihe des Zweiflers* ('The True Consecration of the Sceptic,' published in reply to De Wette's *Theodore* in 1823, and frequently republished and translated with titles such as *Sin and Redemption* and *Guido and Julius*); others are an Anthology of Eastern Mysticism (1825); commentaries, which have been some of them translated into English two or three times over, on Romans, John's Gospel, The Sermon on the Mount, Hebrews, and Psalms; a reply to Strauss; *Andachtsstunden* (Eng. trans. 'Hours of Christian Devotion,' 1875); some volumes of sermons; miscellaneous essays; and contributions to church history—*Lutherische Theologen Wittenbergs* (1852), *Das Akademische Leben des 17ten Jahrhunderts* (1852-54), and the first part of a *Geschichte des Rationalismus* (1865, never finished). A complete edition of his works (11 vols.) appeared at Gotha in 1863–72; and he edited Calvin's Institutes and some of his commentaries. See a sketch by Kähler (1877); and a fuller life by Witte (2 vols. 1884–86).

Thom, WILLIAM, author of *The Mitherless Bairn* and other poems in the Scottish vernacular, was born at Aberdeen in 1799, worked as a handloom weaver there, at Inverurie, and elsewhere, and, after a life of much poverty and distress, died at Hawkhill near Dundee, 28th February 1848. His collected poems were first published in 1845 (new ed., with a memoir, Paisley, 1880).

Thomas, ST, 'the doubting apostle' (see John, xix. 26–29), established the church in Parthia, according to the oldest tradition, and was buried in Edessa. A later tradition carried him to India. See APOCRYPHA. — For Thomas à Becket, see BECKET; for Thomas à Kempis, see KEMPIS; for Thomas of Celano, see DIES IRÆ; and for Thomas Aquinas, see AQUINAS.

Thomas, CHRISTIANS OF ST, or Syrian Church of India, the oldest Christian church in India, numbering in 1891 some 400,000 adherents in the native states of Cochin and Travancore on the Malabar coast. The church professes to have been planted by St Thomas, but is doubtless an offshoot of the Nestorian Church of Persia (in the patriarchate of Babylon), transplanted to India about the beginning of the 6th century. Founded by missionary effort, the Indian Church was probably recruited from Persia by the struggles of Christianity with revived Zoroastrianism and the triumph of Islam. Missionaries from Rome failed in the 14th century to persuade the Indian Christians to accept the authority of Rome; but the influence of Jesuit missionaries succeeded at the Synod of Diamper (Udiamperur, 12 miles SE. of Cochin) in 1599 in nominally bringing the sectaries into the Western Church. The yoke of Rome was, however, thrown off again in 1653, under the leadership of a Syrian Jacobite metropolitan

Gregorius. English Protestant missionaries have established no permanent relations; though dissensions amongst themselves (concerning questions of property) have had to be settled, after years of litigation, before English judges, the ancient church asserts its independence; not even recognising dependence on the patriarch of Antioch, but essentially Nestorian in theology and rites. Their sacred language is Syriac. The clergy are celibate. See GREEK CHURCH; and G. M. Rae, *The Syrian Church in India* (1892).

Thomas, AMBROISE, French musical composer, was born at Metz, 5th August 1811. He entered the Paris Conservatoire in 1828, where he carried off the first prize for piano playing in 1829, for harmony in 1830, following up these two successes by gaining the Grand Prix for musical composition in 1832. Before he had reached the age of twenty-six Thomas had produced a cantata, a *Messe de Requiem* for orchestra, and numerous pieces for pianoforte, violin, and orchestra. His first success in opera was with *La Double Échelle* in 1837, followed by *Mina* (1843), *Betty* (1846), *Le Caïd* (1849), *Le Songe d'une Nuit* (1850), *Le Carnaval de Venise* (1853), *Mignon* (1866), *Hamlet* (1868), *Françoise de Rimini* (1882), with innumerable other operas, cantatas, part-songs, and choral scenas. Thomas was appointed a member of the Institute in 1851, professor of Composition in 1852, and succeeded Auber as director of the Conservatoire in 1871. A Grand Cross of the Legion of Honour (1880), he died 12th February 1896.

Thomas, ARTHUR GORING, born near Eastbourne, 21st November 1851, was educated for the civil service, but took up the study of music at the Paris Conservatoire (1875–77), and then for three years at the Royal Academy of Music, London, and wrote the operas *Esmeralda* (1883) and *Nadeshda* (1885), the cantata *Sun-worshippers* (1881), and many songs. He committed suicide 22d March 1892.

Thomas, GEORGE HENRY, an American general, was born in Virginia in 1816, graduated at West Point and entered the artillery in 1840, gained a brevet for gallantry against the Indians in Florida in 1841, and two others at Monterey and Buena Vista in 1846–47, and in 1855–60 served in Texas as a major of cavalry. In 1861 he was appointed brigadier-general of volunteers, and sent to Kentucky to turn backwoodsmen into soldiers; and with them in January 1862 he won the battle of Mill Springs. He was raised to major-general in April, and in October received the command of five divisions, forming the centre of Rosecrans' army, with which he saved the battle of Stone River (see MURFREESBOROUGH); and at Chickamanga (q.v.) again it was the centre that stood firm, and rendered the victory a barren one for the Confederates. In October 1863 Thomas was given the command of the Army of the Cumberland, and in November led it to the capture of Mission Ridge. In 1864 he commanded the centre in Sherman's advance on Atlanta, and then was sent to oppose Hood in Tennessee; and there in December, with troops that he had had to reorganise, he won the battle of Nashville, and destroyed the last considerable Confederate army in the south-west. For this he was appointed major-general in the United States army, and received the thanks of congress. He afterwards was in command of the military division of the Pacific, and died at San Francisco, 28th March 1870. Thomas was of a nature kindly, gentle, and singularly modest, of unswerving loyalty, and of sterling integrity; a soldier trained in nearly every arm of the service, he won and held without an effort the confidence of all who served under him. There is a Life by Van Horne (1882), and another by Copee ('Great Commanders' series).

Thomas, GEORGE JOHN, born at Tipperary, deserted in India from the navy in 1781, became general to the Begum Somru, and did feats of arms against the Sikhs and French. He died in 1802.

Thomasites. See CHRISTADELPHIANS.

Thomasius, CHRISTIAN, a German philosopher and jurist, was born at Leipzig, 1st January 1655, studied at Frankfort-on-the-Oder (1675–79), and returning to his native town commenced to lecture on law in a style perfectly free from the pedantry of the schools. In 1687, to the astonishment of his Latin-speaking colleagues, he adopted the German language as the vehicle of his expositions, published his programme for the following year in the same tongue, and commenced an unconventional monthly journal. But this work and his advanced views on theological subjects excited so much opposition that he was forced to leave Leipzig, and went first to Berlin, and afterwards (1690) to Halle, where, under the patronage of the Brandenburg court, his lectures were the means of establishing a university, since famous. In this university Thomasius became professor of Jurisprudence, and here he died, 23d September 1728. It is to his credit that he broke away completely from traditional pedantry and mediæval terminology, and introduced better methods into the scientific treatment of various departments of study; and he honourably signalised himself as a courageous opponent of trial for witchcraft and the use of torture. The characteristic features of his mode of thought are contained in his *Gedanken und Erinnerungen* (3 vols. Halle, 1723–26) and in his *Geschichte der Weisheit und Thorheit* (1693). His specialty was international law (*jus naturale*) and ethics. See works on him by Luden (1805), Dernburg (1865), Wagner (1872), and Nicoladini (Berlin, 1887).

Thomas the Rhymer, a name given to the earliest poet of Scotland. The history of his life and writings is involved in much obscurity; but it is generally believed that Thomas Rymour of Ercildoune was the person whose poems and prophecies were extensively known among the people of Scotland at an early period. The Rhymer derived his territorial appellation from the village of Ercildoune (now Earlston), in the county of Berwick. The time of his birth is unknown; but he appears to have reached the height of his reputation in 1286, when he is said to have predicted the death of Alexander III. (q.v.), as recorded in Bower's continuation of the *Scotichronicon*. The Earl of Dunbar, having questioned the Rhymer as to what kind of weather was to be on the morrow, was answered that on that day before noon should be the greatest storm of wind that ever was heard in Scotland. Next day towards noon, the weather being calm, Dunbar expressed a doubt as to the truth of the prediction, when the Rhymer said: 'It is not noon yet;' and immediately thereafter a messenger arrived with the tidings of the king's accidental death at Kinghorn on the previous evening. From this and other prophecies the Rhymer became popularly known as 'True Thomas,' and was believed to have derived his skill from his intercourse with the Queen of Fairyland. The legend bears that he was carried off to Fairyland, and after three years' residence there was permitted to revisit the earth, but still remaining bound to return to his royal mistress when she should intimate her pleasure. Accordingly, one day, when a hart and hind were seen pacing the street of the village, the Rhymer instantly rose and followed them to the forest, never to return. (Compare the myth of TANNHÄUSER.)

The earliest historical document referring to Thomas Rymour of Ercildonne is a charter of Petrus de Haga of Bemersyde, to which the Rhymer's name is appended as a witness; its date is about 1260–70. Again, in a charter of 1294, Thomas of Ercildonne, describing himself as 'son and heir of Thomas Rymour of Ercildonne,' conveys his lands in the village of Ercildonne to the Trinity House of Soltra. From this it has been inferred that the Rhymer was now dead; although Blind Harry, in his *Wallace*, speaks of him in 1296 or 1297 as then 'in to the faile'—the Cluniac priory of Fail in Ayrshire, by Dr Murray's conjecture. The Rhymer is also alluded to by Wynton in his *Chronicle*. Boece calls him Thomas Learmont, and the Russian poet Lermontoff claimed him for an ancestor; but there is no contemporary authority for this surname. Whether Rymour was a family surname or a personal appellation derived from his poetical reputation has also been discussed. The fact that his son, in the charter above referred to, applies the name to his father, but does not take it himself, seems to favour the latter view.

The Rhymer's prophecies were first collected and published in Edinburgh by Waldegrave in 1603. Sir Walter Scott (so also Mr M'Neill) believed him to be the author of the famous romance of *Sir Tristrem*, because his name occurs along with that of the romance in an ambiguous passage in the poems of Robert of Brunne (*c.* 1338). But the romance is now generally believed to have had a French origin, and to be of earlier date than the time of the Rhymer. The other poems attributed to him are chiefly descriptive of his interviews with the Fairy Queen and his adventures in Fairyland; they display poetical power of a very high order.

See *The Romances and Prophecies of Thomas of Ercildoune*, edited by Dr J. A. H. Murray for the Early English Text Society (1875); editions of *Thomas of Ercildoune* by Alois Brandl (Berlin, 1880); *Sir Tristrem*, by Scott (1804), by Kölbing (Heilbronn, 1882), by G. P. M'Neill for the Scottish Text Society (1886); and Professor Child's *Popular Ballads* (part ii. 1884).

Thomasville, capital of Thomas county, Georgia, 200 miles by rail WSW. of Savannah, with boys' and girls' colleges, foundries, &c. Pop. (1880) 2555; (1890) 5514.

Thomists. See AQUINAS.

Thompson, BENJAMIN. See RUMFORD.

Thompson, ELIZABETH. See BUTLER, p. 584.

Thompson, WILLIAM HEPWORTH, Master of Trinity, was born at York in 1810, studied at Trinity College, Cambridge, became regius professor of Greek in 1853, and in 1866 succeeded Whewell as master of his college. A brilliant classical scholar and a profound student of Greek philosophy, he projected a great edition of Plato, but accomplished only the *Phædrus* and *Gorgias*, so that, though by his teaching he left an enduring mark on Cambridge scholarship, he is chiefly remembered by a few incomparable sarcasms. He died 1st October 1886.

Thoms, WILLIAM JOHN, a genial and accomplished antiquary and bibliographer, was born in Westminster, 16th November 1803, and began life as a clerk in the Chelsea Hospital. After twenty years of service there he was attached as a clerk to the House of Lords, and was appointed its deputy-librarian in 1863, a post which he resigned from old age in 1882. He died in London, August 15, 1885. Thoms was elected F.S.A. in 1838, was secretary of the Camden Society from 1838 till 1873, founder of *Notes and Queries* (1849), and its editor down to 1872. His happiness in hitting on names is illustrated in the name and motto of this famous little paper, and in the name supplied (*Athenæum*, August 1846) to the new subject of study, 'folk-lore.' His published writings by no means suggest the range of the vast stores of out-of-the-way knowledge which he possessed and was ever ready to communicate to others. His books include *A Collection of Early Prose Romances* (3 vols. 1828; enlarged ed. 1858); *Lays and Legends of Various Nations* (4 vols. 1834); *Book of the Court* (1838); *Anecdotes and Traditions illustrative of Early English History and Literature* (Camden Soc. 1838); *Three Notelets on Shakespeare* (1864); *Hannah Lightfoot, Queen Charlotte, and Chevalier D'Eon* (1867); *Human Longevity: its Facts and its Fictions* (1873); besides a translation of Worsaae's *Primeval Antiquities of Denmark* (1849), and an edition of Stow's *Survey of London* (1875).

Thomson, SIR CHARLES WYVILLE, zoologist, was born at Bonsyde, Linlithgow, March 5, 1830, and had his education at Merchiston Castle school and the university of Edinburgh. In 1850 he began to lecture on botany at Aberdeen, in 1853 he was appointed to the chair of Natural History in Queen's College, Cork, in 1854 of Mineralogy and Geology in Queen's College, Belfast, and in 1870 to that of Natural History in the university of Edinburgh. He conducted scientific dredging expeditions in the *Lightning* and *Porcupine* (1868–69), and was scientific head of the famous *Challenger* voyage of 68,900 miles for deep-sea explorations (1872–76). He was knighted in 1876, presided over the geographical section of the British Association at Dublin in 1878, and died at Edinburgh, 10th March 1882. His books were *The Depths of the Sea* (1872) and *The Voyage of the Challenger*, a preliminary account of its general results (2 vols. 1877). See CHALLENGER.

Thomson, GEORGE, song-collector and friend of Burns, was born at Limekilns, Fife, about 1759, and educated at Banff, but at seventeen removed to Edinburgh, where he received a clerkship to the Board of Trustees. He rose to be principal clerk, a post which he held for sixty years. In 1792 he formed the idea of collecting every existing Scotch melody, and of giving to the world 'all the fine airs both of the plaintive and lively kind.' The result appeared in six volumes of Scotch songs, followed by two of Irish songs, and three of Welsh melodies. A large number of well-known authors were engaged to supply words to the melodies—among them Thomas Campbell, Professor Smyth, Sir Walter Scott, and Joanna Baillie—but the most prolific writer was the poet Burns, who contributed over 120 songs to the collection. Besides the pianoforte accompaniment, according to Thomson's arrangement, each song was to have a prelude and coda, with accompaniments for violin, flute, and violoncello. For this portion of the *magnum opus* Thomson secured the services of Pleyel, Kozeluch, Haydn, Beethoven (who received £550 for his share of the work), Mozart, Weber, Hummel, Hogarth, and Bishop. Their compositions were pronounced by the *Edinburgh Review* to be wholly unrivalled for originality and beauty. The first volume was published three years after the death of Burns. Thomson died at Leith in 1851, aged ninety-two. See the autobiographical sketch in *The Land of Burns* (1840).

Thomson, JAMES (1700–48), poet, was one of the nine children of the parish minister of Ednam, Roxburghshire, where he was born 11th September 1700. He was educated first at Jedburgh, and then at the university of Edinburgh, where he studied for the church. From his earliest years he had written poetry, though he is said to have, with uncommon discretion, regularly burned his juvenile efforts. Soon after his father's death, deserting

theology for letters, he removed to London provided with little money but much manuscript. Where and how he lived at first is not quite clear, but in 1726 he began with *Winter* the publication of his poem on the *Seasons*. The copyright brought him only three guineas, but Lord Wilmington, to whom it was dedicated, fulfilled the expected duty of a patron by presenting him with twenty guineas. The piece was immediately successful, and Thomson's place as a poet was assured. *Summer* and *Spring* followed in the next two years. The second of these is inscribed to the Countess of Hertford, who invited the author to her country-seat 'to hear her verses and assist her studies.' Johnson records that 'he took more delight in carousing with Lord Hertford and his friends,' and that the lady was in consequence exceedingly indignant. In 1730 *Autumn* completed the *Seasons*. It was published with his collected works, which now included a *Poem on the Death of Sir Isaac Newton*, and *Britannia* (1727), a tirade against Spain's interference with English commerce, and a eulogy of Frederick, Prince of Wales, then in opposition to the court. In 1729 his tragedy of *Sophonisba* was produced. The audience was numerous and splendid, but 'nobody was much affected.' One luckless line, 'O Sophonisba, Sophonisba O,' is still remembered for the famous parody, 'O Jemmy Thomson, Jemmy Thomson O,' which, repeated by everybody, killed what little life there was in the piece. His other tragedies were *Agamemnon* (1738), *Edward and Eleonora* (1739), *Tancred and Sigismunda* (1745, in which Garrick and Mrs Cibber played the principal parts), and *Coriolanus* (produced after his death to pay his debts and aid his sisters). In 1731 Thomson was chosen to accompany Charles Talbot, son of Lord Chancellor Talbot, on the conventional continental tour, then a necessary part of the education of a young man of quality. The travellers visited France, Switzerland, and Italy, and something at least of the improvement in the poet's later work may be ascribed to the fresh impressions received on this delightful journey. On his return Lord Talbot gave him the sinecure office of Secretary of Briefs, but first the son and then the father died, and a new favourite got the appointment. He was not long destitute. The poem of *Liberty* (1732), inspired by his travels, was dedicated to the Prince of Wales, who was induced by Lyttleton to see Thomson. The result of the interview was a pension of £100 a year. He afterwards obtained the appointment of surveyor-general of the Leeward Islands. A deputy did what work there was to be done, and Thomson pocketed £300 a year. In 1740 the *Masque of Alfred* was produced at Cliffden before the Prince and Princess of Wales. It contains the song *Rule Britannia*, still, for want of a better, the popular patriotic ode. Thomson's last years were spent at Richmond, where English scenery is seen at its best. Here he finished his finest work, *The Castle of Indolence*. It was published May 1748. He died on 27th August following. As a man he was kindly, easy, gay, indolent, and of a rare modesty. No wonder he was universally popular. Stanza lxviii. Canto 1 ('written by a friend of the author'—Lord Lyttleton) of his last work pictures him as 'more fat than bard beseems,' as 'void of envy, guile, and lust of gain,' as all

> The world forsaking with a calm disdain,
> Here laughed he careless in his easy seat;
> Here quaff'd encircled with the joyous train,
> Oft moralising sage: his ditty sweet,
> He loathed much to write, nor cared to repeat.

Thomson's poems bear traces of minute and accurate observations of nature at first hand. His impressions were received early, for it is the rustic sights and sounds of the Border that are most prominent in his verse. He was not without a quaint if sometimes coarse humour. He has long passages of pleasing melody, though the exquisite note in his description of the Hebrides, 'placed far amid the melancholy main,' is but rarely heard. His thought is usually conventional and commonplace. No real feeling pulsates through his verse. He is verbose and straggling beyond endurance. His best work is professedly based on and full of echoes of Spenser; but that only reminds us how far the *Castle of Indolence* is below the *Faery Queen*.

See the Lives by Dr Johnson, Gilfillan, and W. M. Rossetti; and Prof. Léon Morel, *James Thomson: Sa Vie et ses Œuvres* (1895).

Thomson, JAMES, the poet of despair, was born a sailor's son at Port-Glasgow on the Clyde, 23d November 1834, and educated in an orphan asylum, where he was trained for service as an army schoolmaster; but through his friend Bradlaugh (q.v.) he became from 1860 onwards a contributor to the *National Reformer*, in which many of his sombre, powerful, and sonorous poems—including 'The City of Dreadful Night' (1874)—first appeared. In 1862 he became a lawyer's clerk; he went to America as a mining agent; was war-correspondent with the Carlists; and from 1875 to the end of his life depended for livelihood largely on contributions to a monthly published by a tobacconist firm. Afflicted in body and profoundly gloomy in mind, he suffered sorely from the seductions both of narcotics and stimulants; and he died in the University College Hospital, 3d June 1882. *The City of Dreadful Night and Other Poems* was published as a book in 1880, praised by the critics and read by the public; and was followed by *Vane's Story, Essays and Phantasies, A Voice from the Nile* (1884, with memoir by Bertram Dobell), and *Shelley, a Poem* (1885). Thomson's pessimism was not academic, but the only too real and dark despair of a morbidly gloomy soul; his monotonously melancholy verses, not seldom tediously verbose, are occasionally varied by a burst of sarcasm or a brief dash of preternatural brightness. He wrote under the pseudonym 'Bysshe Vanolis' (often represented only by the initials B. V.), *Bysshe* being in honour of Shelley and *Vanolis* the acrostic of Novalis.

See the Life by Salt (1889); the edition of the poems by B. Dobell (1895); and the *Biographical and Critical Studies* (1896).

Thomson, JOHN, minister of Duddingston and landscape-painter, was born 1st September 1778 at Dailly in Ayrshire, and, in spite of his wishes to be an artist, was trained to follow the sacred profession of his father and grandfather. He completed his theological studies in Edinburgh, taking some lessons, however, from Nasmyth, the painter, and in 1800 became his father's successor at Dailly. Hence in 1805 he was transferred to the parish of Duddingston near Edinburgh, where, along with the faithful performances of parochial duties, he found time to paint the large series of landscapes in virtue of which he ranks amongst the best, as he was the first of Scottish landscapists. His style, though characteristic, reflects the influence of the Dutch, French, and Italian schools. He died 27th Oct. 1840. See a monograph by W. Baird (1895).

Thomson, JOSEPH, traveller, was born at Thornhill in Dumfriesshire in 1858, studied at Edinburgh University, and went as geologist with the Royal Geographical Society's expedition to Lake Tanganyika under Keith Johnston in 1878. On the death of his chief on the coast (1879), Thomson took the command of the expedition, and carried it out with great success. Put at the head of another expedition of the society in 1882, he

passed through the Masai country, visited Mount Kenia, Lakes Naivasha and Baringo, and Mount Ligonyi. In the service of the National African Company he made an eminently successful journey on the Niger and to Sokoto. For the Geographical Society he explored southern Morocco, and for a company he made a journey in South Africa. He died, after a long illness, 2d August 1895. See the biography by his brother (1896). Among his works are *To the Central African Lakes and Back* (1881); *Through Masai Land* (1885); *Ulu, an African Romance* (with a collaborator, 1888); *Travels in the Atlas* (1889); and Life of Mungo Park (1891).

Thomson, WILLIAM, Archbishop of York, was born 11th February 1819, and studied at Shrewsbury and Queen's College, Oxford. After holding various cures and acting as college tutor, he was in 1845 elected provost of his college. In 1861 he became Bishop of Gloucester and Bristol, and in 1862 Archbishop of York. The best known of the works of this judicious and liberal-minded prelate is his *Outline of the Laws of Thought* (1848), which was followed by several collections of sermons and papers. He died on Christmas Day 1890. See the *Quarterly Review* for April 1892.

Thomson, WILLIAM (Lord Kelvin), one of the most brilliant natural philosophers of the 19th century, was born in Belfast in June 1824. At Cambridge he highly distinguished himself as an original thinker even in his undergraduate days. He was second wrangler and first Smith's prizeman of 1845, and shortly after was elected to a fellowship in St Peter's College. In 1846 he became professor of Natural Philosophy in the university of Glasgow, where his father had been professor of mathematics. All his numerous writings have the stamp of originality in a marked degree. Perhaps the most remarkable of his earlier papers, published in 1842, is the one in which he solves by an analogy derived from the conduction of heat important problems in electrostatics. To him also we owe the solution of the problem of the transmission of electric currents in submarine cables. It was in this connection that he first came prominently before the public, for it was largely through his refined researches that the Atlantic cable was so soon a realised idea. On the successful completion of the cable in 1866 he was knighted. In 1892 he was created a peer with the title of Lord Kelvin. As an inventor of accurate and delicate scientific instruments Lord Kelvin is *facile princeps*. His electrometers of various design—absolute, portable, quadrant, &c.—embody the perfection of mechanical and geometrical adjustment. More recently he has constructed ampere-meters, volt-meters, and watt-meters, suitable alike for the electrical workshop and laboratory. His sounding apparatus and Compass (q.v.) have been adopted by the Admiralty and the principal mercantile lines. In pure science Lord Kelvin has done incomparable work. Specially may be mentioned his thermodynamic researches from 1848 onwards, including the doctrine of the dissipation or degradation of Energy (q.v.); his magnetic and electric discoveries, including general theorems of great value and the beautiful method of electric images, which has proved such a power in all similar investigations; and his work in hydrodynamics, more especially in wave-motion and in vortex-motion. Basing upon the phenomena of gyrostatic motion (see GYROSCOPE) he has imagined a kinetic theory of inertia of high interest; and his dynamical theory of dispersion, and indeed all his views on the nature of the Ether (q.v.) are full of suggestiveness. In 1872 his electrostatic and magnetic papers were reprinted in collected form (2d ed. 1884); and his other papers have been similarly published under the title *Mathematical and Physical Papers* (vols. i.–iii. 1882–90), besides *Popular Lectures* (3 vols. 1889–94). He is joint author with Professor Tait of *A Treatise on Natural Philosophy* (vol. i. 1867; 2d ed. in two parts, 1879), a work which, though never completed, has had an incalculable influence on the progress of physical science. He was president of the British Association (1871), of the Royal Society of London (1890–95), and of the Royal Society of Edinburgh, and is a member of the Institute of France and of the Berlin Academy, and of British, French, Prussian, and other orders. He resigned his professorship after holding it for fifty-three years.

JAMES THOMSON, LL.D., F.R.S., elder brother of Lord Kelvin, succeeded Rankine in 1872 as professor of Engineering in the university of Glasgow. He retired in 1889, and died May 8, 1892. He was an authority on hydraulics, and invented the inward flow vortex turbine. In pure science he is best known as the discoverer of the effect of pressure upon the freezing-point of water. His various papers on elastic fatigue, on under-currents, on trade-winds, and other subjects are all marked by a distinct originality of treatment.

Thor, the god of thunder, was the son of Odin and Earth (Yörd); his wife was Sif. His palace, supported on 540 pillars, was called Thrudvang. Thunder was caused by the rolling of his chariot. He was in the vigour of youth, had a red beard, and was the strongest of all gods and men; the gods even called in his assistance when they were in straits. He was in particular a terror to the Giants (q.v.), with whom he was perpetually at strife, and whom he struck down with his hammer Mjolner, which had the property of returning to his hand after being hurled. The name of Thor was wide-spread; the Anglo-Saxons worshipped him as Thunar, the High Germans as Donar. As rude force is the predominating element in Thor, the humorous element of the Scandinavian belief attaches to him. Thus the giants often blinded him by magic, and made fun of him; yet he always shows his extraordinary strength in these cases, and in the long run his opponents are invariably overcome by the hammer. Thursday is so called from Thor; and the name survives in numerous names of places (Thunderfield in Surrey; Thundersley in Essex; Thurso), and also in personal names (Thorburn; in Scand. Thorbiörn, 'son of Thor'). See SCANDINAVIAN MYTHOLOGY.

Thorax. See CHEST.

Thoreau, HENRY DAVID, a New England author, born in Concord, Massachusetts, July 12, 1817, and died there May 6, 1862. Copyright 1892 in U.S. by J. B. Lippincott Company. Concord is a pretty rural village about 20 miles NW. of Boston, and is noted as having been the home of Emerson, the Alcotts, Hawthorne, and Thoreau, the latter, however, being the only one of the group born there. Thoreau's father, John Thoreau, was of French extraction. He was a merchant in Boston, and finally a lead-pencil maker in a small way in Concord, where he died in 1859. He is described as a small, deaf, and unobtrusive man, plainly clad, and minding his own business; very much in contrast with his wife, who was not small, nor unobtrusive, and who did not always succeed in confining her attention to her own business. Henry was the third of four children—John, Helen, Henry, and Sophia—all people of character and mark. 'To meet one of the Thoreaus,' says Mr Sanborn, the biographer of Henry, 'was not the same as to encounter any other person who might cross your path.' Helen and John were both teachers, and died comparatively young. Helen was evidently a

fine nature. It was part of her earnings as teacher that helped to pay Henry's expenses at Harvard College, where he was graduated in 1837.

Henry did not distinguish himself in college. In his senior year he is said to have 'lost rank with his instructors by his indifference to the ordinary college motives for study.' After graduating he became a teacher, and was for a time employed in the academy at Concord where he had been a pupil. He seems to have begun his career as a lecturer when about twenty-one years of age, first appearing before the lyceum of his native village. He soon gave up teaching, and joined his father in making lead-pencils. But to this employment he did not stick. Having mastered the art, Emerson says, he had no further interest in it. He probably began his walks and studies of nature as the serious occupation of his life about this time—i.e. in 1838 or 1839. In August 1839 he made his voyage down the Concord and Merrimac rivers in company with his brother John. Out of this voyage came his first book, *A Week on the Concord and Merrimac Rivers*, published ten years later. The *Week* is a collection of essays on religious literature and philosophical themes, tied together by a slight thread of travel. Thoreau early made the acquaintance of Emerson, and in 1841–43 was a member of his household, having charge of the garden and doing other work for his friend. When Emerson made his visit to England in 1847, Thoreau again lived with the Emerson family. In 1845 Thoreau borrowed Mr Alcott's axe, and went and built himself a shanty in the woods by Walden Pond on land owned by Mr Emerson. He went there, he said, for seclusion and solitude that he might the better study nature and become acquainted with himself. Here he seems to have written much of the *Week*, his essay on Carlyle, and many others of his papers. While here he demonstrated to himself that a man can support himself on less than $100 per year and have two-thirds of his time to himself. He spent nearly two years at Walden. He says: 'I left the woods for as good a reason as I went there.' Out of his experience has come his most popular book, *Walden, or Life in the Woods* (1854), one of the freshest and most stimulating books in American literature.

After the Walden episode he supported himself in various ways, such as a job here and there at whitewashing, gardening, fence-building, and land-surveying. He also had a call to lecture now and then, and he wrote for the current magazines. He made three trips to the Maine woods in 1846, 1853, and in 1857, where he saw and studied the moose and Indians. His papers which were the outcome of these trips were published in book form after his death (1864), and next to *Walden* form his most valuable and interesting volume. In 1850 he made a trip to Canada with his friend Ellery Channing, out of which trip came his posthumous volume, *A Yankee in Canada* (1866). Thoreau began to keep a daily journal of his walks and observations in 1835. These journals swelled to thirty volumes before he died, and are a complete record of what he saw and what he thought. They seem to have been written and revised with great care, and are rich in fine thoughts, graphic descriptions, and fresh natural history notes. Since his death three volumes have been published from them: *Early Spring in Massachusetts* (1881), *Summer* (1884), and *Winter* (1887). Thoreau died of consumption, sitting up in bed on a morning in early May, and as gently as if going to sleep. Since his death, beside the volumes already named, there have been published from his lectures and magazine articles *Excursions in Field and Forest*, with a biographical sketch by Emerson (1863), and *Cape Cod* (1865). In 1865 a volume of his letters was published under the title of *Letters to Various Persons*, which also included nine of his poems. Thoreau wrote a good many poems, but destroyed most of them on the advice of Emerson. His poetry was much more Emersonian than his prose. He was early brought under Emerson's influence, and in both his manners and his habit of mind that influence was marked. Yet his writings are crisp and tonic, and in the literature of New England perhaps rank second in importance to those of his illustrious neighbour and friend. See Lives by H. A. Page, F. B. Sanborn (1882), H. S. Salt (1890 and 1896).

Thorium (sym. Th, equiv. 231·5) is a rare metal resembling aluminium, but taking fire below a red heat, and burning with great brilliancy. *Thoria*, ThO_2, the oxide, is remarkable for its high specific gravity, 9·2. Thorium was discovered in 1829 by Berzelius in an earth to which he had given the name *Thoria*, and which occurs in a rare black Norwegian mineral termed *Thorite*. A use was found for it in making the mantles for incandescent gas-light (see GAS-LIGHTING).

Thorn. See THORNS, HAWTHORN, SLOE, BUCKTHORN.

Thorn (Pol. *Torun*), a strongly-fortified town in the province of West Prussia, on the right bank of the Vistula (here spanned by a viaduct 1100 yards long), 31 miles by rail ESE. of Bromberg. Founded by the Teutonic order in 1231, and a member of the Hanseatic League, Thorn contains a town-hall and a number of other buildings remarkable for their beautiful gables and interiors; became a Polish town in 1454; and was annexed to Prussia in 1793, and again finally in 1815. It became an important fortified stronghold in the 17th century; was five times besieged between 1629 and 1813; and since 1878 has been made a fortress of the first rank by Prussia, the old fortifications being removed, and a series of detached forts built. Copernicus was a native; and a colossal bronze statue of him was erected in 1853. An active trade in corn and timber is carried on. Pop. (1890) 26,712, of whom two-fifths are German Protestants, the remainder mainly Polish Catholics, with 1200 Jews.—THE CONFERENCE OF THORN, an effort to explain away the differences between Catholics and Protestants, with a view to reunion, was originated by Ladislaus IV. of Poland. It met in August 1645, lapsed into disputation, and broke up in November.

Thornaby-on-Tees. See STOCKTON.

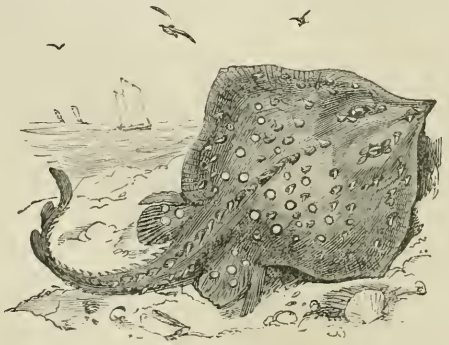
Thorn-apple (*Datura*), a genus of plants of the natural order Solanaceæ, having a tubular five-cleft calyx, a large funnel-shaped five-lobed corolla, a two-laminated stigma, and an imperfectly four-celled, prickly, or unarmed capsule. The species of this genus are annual herbaceous plants, rarely shrubs or trees; they are in general narcotic, and productive of wild excitement or delirium. The common Thorn-apple, or Stramonium (*D. stramonium*), is an annual plant, with smooth stem and leaves, white flowers, and erect prickly capsules, a native of the East Indies, but now often met with in Europe, as also in Asia, the north of Africa, and North America. It contains a peculiar alkaloid, *Daturine*, which is practically identical in its action with atropine. The leaves and seeds are employed in medicine (see ASTHMA). The dried leaves have a faintly narcotic smell, and an unpleasant bitter taste; the seeds, which are of a black colour, are still more poisonous. A variety with pale violet flowers and purplish violet stem is frequently cultivated in gardens as an ornamental plant. Still more narcotic is the Soft-haired Thorn-apple (*D. metel*), a native of the south of

Asia and of Africa. The Thugs (q.v.) of India employed it in order to stupefy their victims, or, in other cases, to poison them outright. From its seeds, along with opium, hemp, and certain spices, a strong intoxicating substance is prepared, which the Mohammedans of India use in order to produce in themselves an indescribable joyfulness and extremely pleasurable feeling for a short time;

Common Thorn-apple (*Datura stramonium*): *a*, ripe fruit.

but the use of it destroys the constitution. *D. tatula*, another Indian species, has similar properties, and is very energetic. *D. sanguinea*, the red thorn-apple of Peru, is used by the Indians to prepare a very powerful narcotic drink called *tonga*, which stupefies when very diluted, and when strong brings on maniacal excitement. The beautiful *D. fastuosa* has flowers externally of a violet colour, and white within, and is cultivated as an ornamental plant, especially a variety with what are called double flowers, which consist rather of two corollas, one within the other. *D. arborea*, a native of Peru and Colombia, has begun to be also very generally cultivated in flower-gardens in Europe. It has very splendid pendulous white flowers, 9 to 12 inches long, which diffuse a sweet smell in the evening and at night.

Thornback (*Raia clavata*), a species of ray or skate, common on most parts of the British coast. It attains a large size; the snout or fronto-nasal



Thornback (*Raia clavata*).

process is short, and the form is nearly rhombic. The upper surface is brown, with lighter spots, the under surface white. The upper surface is rough with minute sharp scales, and has numerous nail-like crooked spines, each with an oval bony base. A few strong spines may also occur on the ventral surface, especially in the female. In the male the teeth are pointed, in the female flat. The thornback is used as food, particularly in autumn and winter, but is most abundantly captured in spring and summer, when it approaches the shore to deposit its eggs.

Thornbury, George Walter, was born in London, a solicitor's son, in 1828, and, after studying art for a while, at seventeen began writing for the *Bristol Journal*. He soon settled in London, and published between twenty and thirty novels, books of travel, and other works, among them the fiery *Songs of the Cavaliers and Roundheads* (1857), *As the Crow Flies* (1859), *Life of Turner* (1861), *Historical and Legendary Ballads* (1875), and vols. i. and ii. of *Old and New London* (completed by E. Walford, 1872–78). He died 11th June 1876.

Thornhill, a town in the West Riding of Yorkshire, 1½ mile S. of Dewsbury, with an old church. Pop. (1881) 8843; (1891) 9606.

Thornhill, Sir James (1676–1734), historical painter and sergeant-painter to Queen Anne, decorated the dome of St Paul's, executed paintings for Blenheim, parts of Hampton Court, and Greenwich Hospital. Of his easel-pictures the best known is the view of the House of Commons in 1730; and he executed a few portraits, some etchings, and good copies of Raphael's cartoons. He founded a successful drawing-school, his most famous pupil being Hogarth, his future son-in-law. Knighted by George I. in 1715, he sat in parliament as member for his native borough of Melcombe Regis.

Thorns, or Spines, are hard, pointed, woody structures. They are metamorphosed leaves or parts of leaves, as is shown by their position on plants; for lateral buds occur in their axils—i.e. in the angle made by them with the internodes (parts of stem) above their insertions, which is one of the characteristics of leaves. In the Barberry the compound spines are entire metamorphosed leaves; in *Robinia pseudacacia* the spines are metamorphosed stipules, parts of the leaf-sheathes; in many species of Caragana and Astragalus they are pointed persistent petioles (leaf-stalks). The thorns of the Blackthorn and Hawthorn are pointed branches; in the Furze (whin) they are both pointed leaves and stems. They are to be distinguished from Prickles (q.v.), which are merely pointed projections of the epidermis, and are therefore to be compared with hairs and surface-glands. Spines, and prickles also, tend to disappear from plants under cultivation—i.e. from plants that are growing luxuriantly; and conversely, they tend to increase in plants growing in unfavourable conditions. These and other facts have led to the theory that spines in general are an expression of the 'ebbing vitality of a species,' and not, as is usually thought, the result of a process of natural selection which has caused them to be evolved as protections against mammals. But this theory has been severely criticised by Mr A. R. Wallace in his *Darwinism*, who argues that spinous plants are vigorous and have an extensive range; and, further, that they are very rare or entirely absent from those districts, oceanic islands for instance, where there are few or no mammals, which is what the theory of their selection as protective organs would lead one to expect; and genera which have many spinous species in other countries have no such representatives in oceanic islands.

Thornycroft, Hamo, R.A., sculptor, was born in London, 9th March 1850, and studied at the Royal Academy schools. 'Artemis' (1880) was

his first success; others were 'Teucer' (1881), 'The Mower' (1884), and the portrait statues of General Gordon in Trafalgar Square (1885) and of John Bright at Rochdale (1892).

Thorough Bass means either what has, as *figured* bass, been explained at ACCOMPANIMENT—a bass voice-part written at length, with numerals written below (or above) it to indicate the chords of the harmony; or, more loosely, the science of harmonic composition. See HARMONY, COUNTERPOINT.

Thorpe, BENJAMIN (born 1782; died at Chiswick, 19th July 1870), edited numerous Anglo-Saxon texts, and was the author of *Northern Mythology* (3 vols. 1852).

Thorwaldsen, BERTEL, sculptor, was born at sea on the 19th November 1770. His father, an Icelander, was on his way to Copenhagen, where he settled as a carver of figure-heads for ships; and the son was brought up to the same profession. But from his eleventh year the boy attended art classes, and in 1793 he gained the first gold medal for design at the Academy of Copenhagen, and along with it the privilege of three years' residence abroad for the purpose of study. Accordingly, in 1796 he sailed for Rome, whose collections kindled in him the undying ambition to revive the glories of sculpture as practised by the ancient Greeks. From Canova he had early and generous recognition; and shortly, by the model for a 'Jason,' he secured reputation. No purchaser could, however, be found for it till, in 1803, just as in hopeless disgust the artist was about to return to Copenhagen, he received from 'Anastasius' Hope a commission for its production in marble. From this time forward prosperity and fame flowed upon him in full tide. In 1819 he returned to Denmark, where his reception was triumphal. He remained at home but a year, and then returning to Rome continued to prosecute his art assiduously up to 1838, when he again departed, to pass his remaining years in his own land. Its climate, however, proved no longer suitable to him, and the year 1841 found him once more at Rome. In 1844, having revisited Copenhagen to complete some of his works there, he died suddenly in the theatre, of disease of the heart, on the 24th March. All the works remaining in his possession he bequeathed to his country, to be preserved in a museum bearing his name, for the maintenance of which he also left the bulk of his fortune, reserving a sufficient provision for his natural daughter; and this collection is now one of the chief glories of Copenhagen. Thorwaldsen's strength lay in classical and mythological subjects; he imitated with wonderful success the antique conceptions, or even may be fairly said to have reproduced classic art. His efforts in Christian subjects, even the famous 'Christ and the Twelve Apostles' at Copenhagen, are obviously a less spontaneous outcome of his genius. Of his many works those best known by photography and otherwise are the reliefs 'Night' and 'Morning.' Of his many portrait busts or statues those of Byron, now at Cambridge, and Œhlenschläger are perhaps the most notable.

See the Life of Thorwaldsen (whose name is in Danish spelt Thorvaldsen) by Thiele (3 vols. Leip. 1852–56; Eng. abridgment by Barnard, 1865); Hammerich, *Thorwaldsen und seine Kunst* (Gotha, 1876); Eugène Plon, *Thorwaldsen, sa Vie et ses Œuvres* (Eng. trans. by Mrs Cashel Hoey, 1874); and Sigurd Muller (Copenhagen, 1890 *et seq.*).

Thoth, the Egyptian Hermes or Mercury, the mythical inventor of the arts and sciences, music and astronomy, and especially of speech and hieroglyphs or letters, over which he was supposed to preside. See EGYPT, Vol. IV. p. 235.

Thou (Lat. *Thuanus*), JACQUES-AUGUSTE DE, the most famous historian of his time, was born at Paris in 1553. His father and grandfather had both been presidents of the parliament of Paris, so that he inherited connections which smoothed his own way to fame and place. After five years spent at the university of Paris he continued his studies at Orleans, and subsequently at Valence under the famous jurist Cujacius. At Valence, also, he formed a friendship, equally honourable to both, with the younger Scaliger. Returning to Paris, he witnessed the massacre of St Bartholomew (1572), of which, though a good Catholic, he afterwards spoke with the severest reprobation. A journey to Italy extended his knowledge and turned his mind still more decidedly to the writing of his great history, the plan of which he had already conceived. He had originally chosen the church as his profession, and actually became one of the canons of Notre Dame in Paris; but at the instance of his friends, though against his own wish, he eventually followed the law. His own merit and his family interest brought him rapid promotion; and at the age of thirty-five he obtained the reversion of the office of president of the parliament of Paris. During the wars of the League De Thou stood fast by Henry III., though he was fully aware of his shortcomings as a king, and took a prominent part in the intricate diplomacy of the time. He stood equally high in the opinion of Henry IV., under whom he acted as keeper of the Royal Library, a post which brought him into contact with the great scholars of the time, the elder Casaubon among others. In affairs of state his most distinguished services were rendered in connection with the Edict of Nantes (1598–99), for which his personal character and the esteem in which he was held by Huguenot and Catholic alike eminently fitted him. He died at Paris in 1617.

The great work of De Thou's life was his stupendous history of his own time (1543–1607), written in Latin, filling four closely-printed folios, and comprising 180 books. The appearance in 1604 of the first eighteen books brought its author a European reputation, and those that followed had equal success. His impartial treatment of heretics, however, did not find favour at Rome; and much to the chagrin of De Thou, who was at heart a pious son of the church, his history was placed on the index of prohibited books. During the 17th and 18th centuries De Thou was ranked with the greatest historians, and he was universally quoted as a master of political wisdom. In England Dr Johnson had serious thoughts of translating him; Pitt paid him a special tribute in the House of Commons; and the best edition of his history was published in London by Samuel Buckley at the expense of Dr Meade, and partly under the superintendence of the historian Carte. His commentaries on his own life and a quantity of Latin verses were De Thou's other contributions to literature.

The following are the chief editions of De Thou's History—11 vols. 8vo, Paris, 1609–14; 4 vols. fol., Frankfort, 1625; French translation, 10 vols. 8vo, Paris, 1740; English edition by Samuel Buckley (7 vols. Lond. 1733). For an account of De Thou's life, see Collinson, *Life of Thuanus* (Lond. 1807; chiefly based on De Thou's own Memoirs); and Philarète Chasles, *Discours sur la Vie et les Ouvrages de J.-A. de Thou* (Paris, 1824). And see Stirling-Maxwell, *Miscellaneous Essays* (1891).

Thought-reading, or MIND-READING, a term which came up in 1881 to designate the act or art of discerning what is passing in another's mind by some direct and unexplained method, depending neither on gesture, facial expression, nor any articulate or other voluntary indication. Thus, if A has hid a penknife in some extremely unlikely

place, B, it is alleged, may, if a susceptible person, be guided to the place so as to discover the object hid without any assistance from A other than being permitted to hold the back of his (B's) hand on A's forehead. The believing explanation is that thought-force, nervous energy, or the like passes in a perfectly natural but as yet unexplained manner through A's forehead into B's hand, and so to B's mind. The unbelieving theory is that A inevitably, but quite unconsciously, communicates a succession of slight but sufficient muscular indications to B, which B instinctively follows without being aware of them severally. Enthusiasts have sought to include thought-reading in the sphere of spiritualism; see the *Proceedings of the Psychical Research Society.*

Thourout, a town in the Belgian province of West Flanders, 11 miles SW. of Bruges. Of great commercial importance in the middle ages, it now manufactures linens and hats. Pop. 8972.

Thousand Islands. See ST LAWRENCE.

Thrace, a name used by the ancients somewhat vaguely for a large region to the west of the Euxine (Black Sea) so as to include the whole country between the Ister (Danube) and the Ægean, and even part of the Scythian country beyond the Ister. Under the Romans, however, part of this vast region was joined to Macedonia; the country between the Ister and the Hæmus (Balkans) became the province of Mœsia (mod. Bulgaria); so that the province of Thracia was the remaining district between the Hæmus and the Propontis, and from the Nestus River (mod. Karasu) to the Euxine; see the map of the Roman empire, Vol. VIII. Thracia was hilly in surface, Rhodope (q.v.) being the chief mountain-system; the chief river was the Hebrus (Maritza); great part of the area was occupied by forest. Who the ancient Thracians were has been much disputed; their language has perished utterly; but there seems no doubt that they were a branch of the Indo-European stock, and kinsmen, more or less remote, of the Greeks, though they were regarded by the Greeks as barbarians. Thrace never constituted one powerful monarchy, though at times the kings of one or other of the Thracian clans extended his power over great part of the country, so as to be formidable to the Athenian colonists or to the Macedonian monarchs. The accepted Roman suzerainty long remained half independent; but under Vespasian Thrace became a province of the empire, and its people became Romanised so entirely that it seems not improbable the Thracian provincials were the direct ancestors of the Vlachs, speaking Roumanian, who are still numerous south of the Danube. Goths and Huns overran the country; Bulgarians occupied the north; and since the conquest of Constantinople by the Turks the fortunes of Thrace have been largely bound up with those of that city. Latterly the northern part of Thrace has become the province of Eastern Roumelia (see BULGARIA), while the remainder is still an integral part of the Ottoman empire.

Thrale. See PIOZZI.

Thrashing is the separating of the grain or seeds of plants from the straw. The earliest method was doubtless the beating out of the grain from the ears with a stick. An improvement on this was the practice of the ancient Egyptians and Israelites of spreading out the loosened sheaves of grain on a circular piece of hard ground 50 to 100 feet in diameter, and driving oxen backwards and forwards over it, so as to tread the grain out; but, as this damaged part of the grain, it was partially superseded by the thrashing sledge, a heavy frame mounted on three rollers, which was dragged over the heaps of sheaves. Similar methods of thrashing were employed by the Greeks and Romans—the stick, the treading by men or horses, and the thrashing-sledge being found in common use among them. The primitive implement in northern Europe was the stick, and an improved modification of it, the *flail* (two sticks loosely fastened together at one end by stout thongs), has not yet disappeared.

Various attempts were made to supersede the flail by a machine, but with little success, till 1787, when Andrew Meikle, an ingenious Scotch mechanic, produced a thrashing-mill so perfect that even after having run the gauntlet of nearly a century of improvers it is essentially the machine of its original inventor. In Meikle's mill the sheaves are loosened and spread out one by one on the feeding-board, A (fig. 1), with the ears towards the machine; they are then pushed forward till caught between two revolving fluted rollers of cast-iron, B; and as soon as one sheaf disappears between the rollers another is presented to them. Behind the rollers is

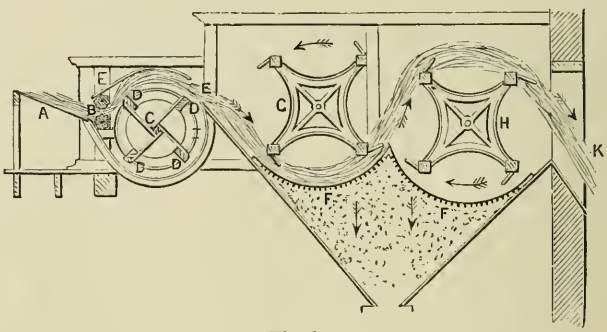


Fig. 1.

a rapidly revolving *drum* or cylinder, C, having four *beaters*, D, D, D, D, or spars of wood armed with iron placed along its surface parallel to its axle; and these beaters, striking the heads as they are protruded from between the rollers, detach the seeds and husks. Grain and straw then pass together over the cylinder, the former falling through the wire-work, F, F, while the straw is carried forward by the circular rakes, G, H, and, being by them thoroughly tossed and separated from the grain and chaff, is ejected at K. The grain which has fallen through the wire-work is received into a winnowing-machine, where it is cleansed from chaff, &c., and then is either discharged upon the barn-floor or, as is the case with the most improved machines, is raised by a series of buckets fixed on an endless web, and again winnowed, to separate the perfect grains from the light and small seeds. Barley is, previous to the second winnowing, subjected to the process of 'hummelling,' by which the awns are removed; but the rest of the process is the same as above.

The earlier alterations upon Meikle's invention were chiefly confined to modifications of the drum; such as diminishing the distance between the drum and its cover, E, E, increasing the number of the beaters, and accelerating the speed of the drum. The speed of the thrashing-machine was next increased, while appliances were attached by means of which at the one operation the grain was thrashed, dressed ready for market, elevated to the granary, and perhaps even sacked, the straw being carried on endless webs to any given part of the straw barn.

The portable thrashing-machine, now so generally employed in America and England, and to a lesser extent in Scotland, has not the two grooved rollers, the loosened sheaf being at once submitted to the action of the thrashing-machinery; the drum, which is a *high-speed drum*, is provided with six or eight beaters, and its cover is capable of being set at any required distance from it by means of screws.

The attention of inventors and manufacturers of thrashing-machines has been turned of late not only to the question of securing increased speed and more finished work, but also to providing against the risk of accidents to those employed about the mills. The feeding of those high-speed drums which were getting so common was attended with considerable danger, and to prevent this safety-drums of different patterns have been introduced by the various makers. The best of these are so effective that accidents in feeding now rarely occur. Some of the modern machines thrash from 12 to 16 or even more quarters of oats per hour. From 6 to 8 quarters per hour are common quantities even for comparatively small machines.

The driving-power is wind, water, horse-power, or steam; but the first is so very uncertain and unequal in its operation that it has nowadays been mostly superseded by the others. Water-power is always desirable, and when it can be had in sufficient quantity or regularly it is much to be preferred in point of economy, its mode of application to thrashing being either by the ordinary Water-power (q.v.) or by Barker's Mill (q.v.). Horse-power was the agent in most common use in the earlier days of thrashing-mills, the horses being yoked to beams attached to a vertical revolving shaft which communicated motion by means of bevelled gear to the thrashing-machine. But it was found that this kind of work was very trying for the horses, and interfered considerably with the other work of the farm; and accordingly steam-power, as being more economical, has extensively superseded horse-labour, engines of 4 to 10

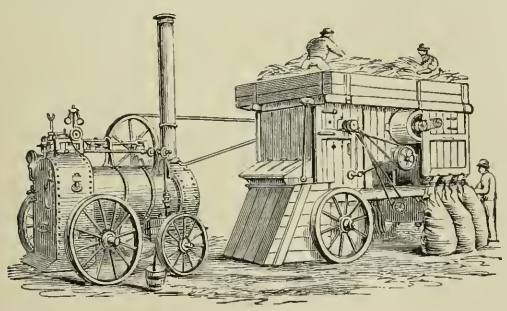

Fig. 2.

horse-power being generally employed. Portable thrashing mills and engines (fig. 2) are thought by many to be more economical, from their saving the labour of transporting the crop from the stack to the barn, and from their adaptability to the requirements of a farmer who may rent more than one holding in a district. On the other hand, however, some prefer the fixed machine on account of cheapness and diminished liability to derangement. Hand-power thrashing-machines are made for use on small holdings. They are hard to drive, but do their work admirably.

Thrasimene. See TRASIMENE.

Thrasybu'lus, Athenian general and statesman, fought in many campaigns at home and abroad, and was a strenuous supporter of the democracy. In 411 B.C. he helped to overthrow the oligarchy of the Four Hundred, and was banished by the Thirty Tyrants, but restored the democracy in 403. He conquered Lesbos, and defended Rhodes, but was slain in 389.

Thread-cells, another name for Stinging-cells (q.v.), given on account of the coiled thread or lasso that springs out and stings.

Thread-manufacture. Any fibrous substance, such as cotton or flax, when it is to be woven, is first spun into yarn, which is sometimes called thread. Sewing-thread, however, always consists of at least two or more yarns twisted together. In the spinning of yarn the process is the same whether it is to be woven into cloth or twisted into thread (see SPINNING). Beginning with the spun yarn, the stages in the process of manufacturing a six-cord cotton thread (a very common kind) are: (1) The yarn is doubled and wound upon bobbins; (2) the double yarn is then twisted into a two-ply thread; (3) the thread is next rewound on bobbins for the second twist; (4) the thread is twisted a second time on the twisting-frame, three two-ply threads being thus formed into a six-cord thread; (5) the thread is rewound on large bobbins, from which it is reeled into hanks for bleaching or dyeing; (6) the bleached or dyed thread is next rewound on bobbins for spooling; (7) spooling—i.e. winding the thread on small bobbins called spools or pirns for use. The spindles of the spooling-machine run at a speed of 7000 revolutions per minute. See also BOBBIN.

Cotton thread is made at Manchester and in its neighbourhood, as well as at Glasgow. Paisley is, however, the principal seat of the manufacture in Great Britain. The making of thread on an industrial scale was begun in that town in 1722 by Christian Shaw of Bargarran. She had obtained information from Holland about the process of making linen thread, and what she and her friends manufactured was sold at the time under the name of 'Balgarran thread.' The industry did not become of great importance so long as flax was the material used. But in the early part of the 19th century, when the spinning-machines of Hargreaves, Arkwright, and others came largely into use, the manufacture of cotton thread was begun in Paisley, and its progress has been on the whole rapid. This has been especially the case since 1860 through the constantly increasing use of sewing-machines for both domestic and factory purposes. From 10,000 to 12,000 hands are employed at the Paisley thread-mills. The mills of J. & P. Coats, Limited, are spread over 40 acres of ground, and give employment to fully 5000 persons. Of late there has been a marked tendency to group the great cotton thread firms in Scotland, the north of England, and the United States in two or three great syndicates, the chief Paisley firms combining in the first instance.

Linen thread is made at Johnstone near Paisley, Belfast, Nottingham, and other places. Although a much less quantity of it is manufactured, it is perhaps used for a greater variety of purposes than cotton thread. Fine kinds are required for lace-making, and strong kinds for sewing heavy fabrics, as well as for shoemakers', saddlers', and bookbinders' use. Silk thread, the stronger kinds of which are called twist, is now used to a very large extent for sewing dyed articles of dress.

Threadneedle Street, in the City of London, got its name from the Merchant Taylors' Company, whose present hall is built on an estate acquired by them as early as 1331. It leads from Bishopsgate Street to the Bank of England, which hence is often called the 'Old Lady in Threadneedle Street.'

Thread-worms, a popular name for Nematoda, a class of more or less thread-like worms,

many of which are parasitic, while others are free-living. The body is unsegmented; there is a well-developed cuticle; there is a complete alimentary canal surrounded anteriorly by a nerve-ring from which six nerves run forward and backward. The sexes are separate, and the life-history is often intricate. Several species are often parasitic in man—*Ascaris lumbricoides*, in the small intestine; *Oxyuris vermicularis*, in the cæcum and large intestine; *Dochmius duodenalis*, in the small intestine; *Filaria sanguinia hominis*, in the blood; *Dracunculus medinensis*, the Guinea-worm; *Trichina spiralis; Trichocephalus dispar*, in the cæcum and large intestine. Not a few are parasitic on plants—e.g. several species of Tylenchus, which infest wheat and other crops. Some occur in domesticated animals—e.g. *Strongylus armatris*, the palisade worm, which causes aneurism in the horse, or *Filaria immitis*, in the heart of the dog, or Ollulanus, which passes from mouse to cat. Others live freely in water and putrefying substances—e.g. Enoplius and many other genera.

See Ascaris, Guinea-worm, Parasitism, Trichina; Leuckart, *Parasites of Man* (1876; Eng. trans. 1886); Schneider, *Monographie der Nematoden* (1876).

Threats, considered legally, are intimidation by moral terrorism. Their purpose is to make the person threatened surrender some right, or pay money, or do something to his detriment from fear of a greater evil. The usual form of the crime is sending anonymously or otherwise a threatening letter demanding money or valuable property, under the menace that the victim will be murdered, or his house or property will be destroyed, or his cattle killed or wounded, or that he will be charged with some infamous crime. (The offence is committed though a guilty person be threatened.) To procure the execution of a deed by threats, or to threaten to publish a libel, are varieties of the same offence. In their extreme form such acts are punished with penal servitude for life.

Three Kings, Feast of the, a famous mediæval festival, identical with Epiphany or Twelfth Night. For the kings, see Magi.

Three Rivers (*Trois Rivières*), capital of St Maurice county, Quebec, at the confluence of the St Maurice and St Lawrence, 95 miles by rail NE. of Montreal. It has a large trade in lumber, over $1,000,000 being invested in mills and booms where logs are accumulated on the St Maurice; and it manufactures boots and shoes, and great numbers of car-wheels and stoves from the bog-iron ore of the vicinity. Three Rivers was founded by Champlain in 1634; a severe battle fought here on 16th June 1776 proved disastrous to the Americans. The city is the seat of a Roman Catholic bishop. Pop. 9296.—Three Rivers, Michigan, on the St Joseph River, 128 miles by rail E. of Chicago, has valuable mineral springs; pop. 3500.

Threshing. See Thrashing.—For Thresher, see Fox-shark.

Thrift. See Annuities, Domestic Economy, Friendly Societies, Insurance, Savings Banks.

Thrift (*Armeria*), a genus of plants of the natural order Plumbaginæ, having the flowers collected into a rounded head, a funnel-shaped, dry, and membranous calyx, five petals united at the base, and narrow, often grass-like, leaves. Two species are included in the British flora, but one of them (*A. plantaginea*) is only found wild in Jersey. The other (*A. vulgaris*) grows in turf-like tufts, with linear leaves, scapes a few inches high, and beautiful rose-coloured, purple, or white flowers, an ornament of the seacoasts of Britain and of Europe generally, and also frequently found on high mountains. Under the names of thrift or sea-pink it is often planted in gardens as an edging, for which it is very suitable, being of a fresh green all the year, and exhibiting its fine flowers in profusion in July and August; but it requires to be renewed every two or three years, the smallest rootless sets growing, however, with great readiness in the moist weather of spring. The flowers are an active diuretic.

Common Thrift (*Armeria vulgaris*).

Thring, Edward, a great educationist, was born at Alford Rectory in Somersetshire, November 29, 1821, and had his education at Eton and King's College, Cambridge, of which he was elected fellow. He took orders, and served in curacies at Gloucester and elsewhere, but in September 1853 found the work of his life in the appointment to be head-master of Uppingham school. He found it insignificant, but made it one of the healthiest and best equipped among the public schools of England. He finally limited the number of boys to 330, thirty to each boarding-house, and he gave himself for thirty-four years with restless energy to the task of educating these in the highest sense of the word. No man ever estimated more highly the worth of life: no schoolmaster since Arnold has been more successful in imprinting upon the characters of his pupils a high ideal of duty as the great end of life. The manly fibre of his own nature, his earnestness and honesty, his firm discipline, and his stern denunciation of cowardice and wrong gave a distinctive character to the school. He died October 22, 1887. His works include volumes of school songs and lyrics, an English grammar, a Latin gradual and a construing book; *Thoughts on Life Science*, anonymously (1869), *The Theory and Practice of Teaching* (1883), Uppingham *Sermons* (2 vols. 1886), *Addresses* (1887), *Poems and Translations* (1887), and *Uppingham School Songs and Borth Lyrics* (1887)—Borth was the Cardiganshire village to which the school removed on the outbreak of scarlet fever in 1874.

See J. H. Skrine, *A Memory of Edward Thring* (1889); H. D. Rawnsley, *Edward Thring* (1889); the Biography by Principal Parkin appeared in 1898.

Thrips. See Corn Insects.

Throat, Affections of the. The term throat is applied somewhat loosely to the back of the mouth and front of the neck; its diseases may therefore be taken to include those of the Larynx (q.v.) and upper part of the trachea, of the upper part of the œsophagus, and of the thyroid gland (see Goitre). Sore throat, however, as commonly used, refers to inflamed and painful conditions of the tonsils and neighbouring parts (see under Palate), which are numerous. One of the most important (Quinsy, q.v.) has already been discussed; and those attending diphtheria, measles, scarlet fever, syphilis, and other infectious and contagious diseases are sufficiently referred to under their several headings. Sore throat may also be a result of the gouty or rheumatic diathesis, or of the action of certain

drugs (especially belladonna and iodide of potassium). See also THRUSH, MUMPS, &c. A few other conditions remain to be considered here.

The disease popularly known as *Clergyman's Sore Throat* first shows itself by huskiness of the voice, with more or less coughing, hacking, and expectorating, from an uneasy sensation in the throat; there is, moreover, a constant inclination to swallow. On examining the back of the throat, its mucous membrane is seen covered with elevations, caused by an accumulation of secretion in the follicles, which sometimes burst and discharge their contents, which are of an elastic consistent nature. This discharge is occasionally followed by ulceration. The disease commonly arises from too prolonged or powerful exercise of the voice by persons in whom the mucous membrane of the throat is in a relaxed condition. Perfect rest from public speaking, preaching, acting, &c. is of more importance than anything else in the way of treatment, and a residence during the winter and spring in a mild and equable climate is expedient. Tonics, such as iron, quinia, and strychnia, should be tried, but local applications are usually of far more service than internal remedies. The most important of these are strong caustics, carefully applied by the surgeon to the affected spots: solid nitrate of silver, 'London paste' (equal parts of caustic soda and unslaked lime), and the galvano-cautery are among the means chiefly employed.

Simple or *catarrhal sore throat* is usually a slight affection, most common in young persons, and often resulting from cold. The throat is reddened, but little swollen. A day or two in the house is usually sufficient to effect its disappearance; the sucking of astringent lozenges (e.g. tannin or red gum) or chlorate of potash pellets is also useful. In its chronic form (*relaxed sore throat*) it is more troublesome, but will generally yield to continued use of astringent lozenges, or the application, twice a day with a brush, of glycerine of tannic acid, or solution of perchloride of iron (one drachm to the ounce of water), if attention be at the same time paid to the general health.

Ulcerated sore throat is generally the result of unhealthy conditions acting on persons in a weakly state. It is particularly common in nurses and students occupied in hospital work, and is generally speedily recovered from when the patient is placed in healthy surroundings and put upon tonic treatment. The white spots seen on the tonsils in *follicular tonsillitis*, a more common and slighter affection, are often mistaken for ulcers, but they really consist of excessive and thickened secretion from the recesses of the tonsil.

Cutting the throat is comparatively seldom the result of accident; it is more often due to a murderous attack, and most frequently to an attempt at suicide. The first duty of the surgeon in treating a case of cut throat is to arrest the flow of blood. Ligatures should be applied to wounded arteries, and steady pressure with the finger (beneath which a small pad of lint is placed) to wounded veins, such as the external jugular. If the internal jugular is wounded, fatal hæmorrhage will very rapidly ensue, unless the wound is immediately plugged with small pieces of sponge, or pressure with the finger is maintained as long as necessary. With a knowledge of these means of checking hæmorrhage by pressure, an intelligent non-professional person may be the means of saving life. When the bleeding has completely ceased, but not till then, means may be taken for bringing together the edges of the wound. When the air-passages are wounded there is great risk of the occurrence of bronchitis or pneumonia, and the patient must be kept in a warm room, and care taken to prevent either food or discharges from the wound from passing down the windpipe. See Sir M. Mackenzie's *Diseases of Throat and Nose*.

Throgmorton, SIR NICHOLAS (1513–71), distinguished himself at the battle of Pinkie, was Queen Elizabeth's ambassador in France, where he was imprisoned as having sided with the Huguenots, and was repeatedly ambassador to Scotland in the troublous period 1561–67. In 1569 he was sent to the Tower for a time as being concerned in the scheme for marrying Mary Queen of Scots to the Duke of Norfolk.

Thrombosis (Gr. *thrombos*, 'a clot of blood'), an affection of the blood-vessels (either veins or arteries), which essentially consists in a coagulation of blood (forming a true clot) at a certain fixed spot. Under certain morbid conditions the blood has a tendency to coagulate in its vessels during life on the least provocation. Thus, slight pressure on the side of a vein will sometimes induce this coagulation, while in other cases it is due to inflammation of the tissues which surround a vein, or laceration of a vein (as when the placenta is expelled from the uterus). A clot thus formed in a vessel may increase and extend from one to another, till it reaches and finally fills a large vessel.

Throndhjem. See TRONDHJEM.

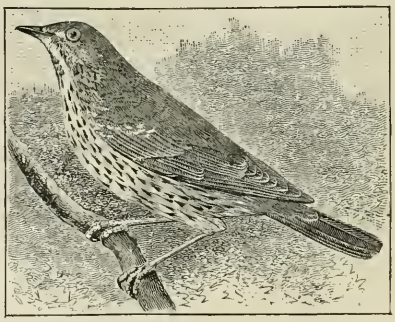
Thrush (*Turdus*), a genus of Passerine birds of the family Turdidæ. The bill is of moderate size and slightly convex; the gape is furnished with hairs; the nostrils lie at the base of the bill, partly covered by a membrane; the first wing-feather is very short; and the outer and middle toes are connected at the base. The genus includes numerous species widely distributed throughout temperate

Missel Thrush (*Turdus viscivorus*).

and even cold regions. The largest known British species is the Missel Thrush (*T. viscivorus*), sometimes called the 'storm-cock' from its habit of singing before or during wind or rain. It breeds freely throughout the British Islands, but migrates from the colder regions on the approach of winter. It breeds early in the year; its nest is usually in the fork of a tree, and neatly lined with grasses and moss. The adult male measures about 11 inches; the prevailing colour of the upper parts is grayish brown, under parts brownish white, with dark spots.

The Song Thrush or Mavis (*T. musicus*) also occurs in almost all parts of Britain. It resembles the missel thrush in general appearance, but is smaller in size, of a more olive-brown colour, and possesses finer powers of song. The nest of the song thrush is usually composed of roots and grasses, lined with a thin coating of mud, decayed wood, or dung. The eggs are of a greenish-blue colour, with black or brown markings, and in the warmer parts of the country two broods are reared in a season. The food of the

song thrush consists of berries, insects, worms, and small molluscs, the shells of the last being broken by repeated knocking against a stone. Other species either resident in Britain or visiting it for a part of the year are the Blackbird (*T.*



Song Thrush (*Turdus musicus*).

merula), the Fieldfare (*T. pilaris*), the Redwing (*T. iliacus*), and the Ring-ouzel (*T. torquatus*), all of which are described in separate articles. The genus Turdus is represented in North America by the Wood Thrush (*T. mustelinus*) and several other species. The flesh of all the thrushes is esteemed a delicacy, and they are snared in enormous numbers while they are assembling for their winter migration.

Thrush, known also as *Infantile Sore Mouth*, is commonly a disease of early infancy, although it may occur at any age. Its characteristic symptom is the presence of small roundish white specks or patches (Aphthæ, q.v.) on the lining membrane of the cavity of the mouth and throat, on the surface of the tongue, the angles of the lips, &c. In thrush crops of these little patches commonly succeed one another. They render the mouth hot and tender, in consequence of which the act of sucking is accompanied by difficulty and pain. In association with these local symptoms are indications of general constitutional disturbance, such as feverishness, drowsiness, sickness, flatulence, colicky pains, diarrhœa, &c. The complaint sometimes seems to be the result of improper diet, or of imperfect attention to cleanliness of the bottle, &c., if the child is being brought up by hand, or of unwholesome milk from a diseased or intemperate nurse; of bad ventilation, &c.; but in some cases the cause of the disease is not evident. The disorder usually lasts eight or ten days, and is only attended with danger when the local affection runs into a low form of gangrenous ulceration. As a local application to the patches glycerine or honey of borax may be applied with a camel-hair pencil; or a pinch of a mixture of powdered borax and loaf-sugar (1 to 8 or 10) may be placed occasionally on the tongue, and the infant allowed to spread it over the mouth. An occasional dose of gray powder may be required; and in some cases a little brandy, or small doses of quinine and iron.

Thrush, or Frush, in the horse, consists in inflammation of the sensitive surfaces within the frog, giving rise to a fetid discharge, constituting unsoundness, and sometimes causing lameness. Want of cleanliness is the chief cause. Daily, when the horse returns to his stable, the foot should be washed out with soap and water, carefully dried, and the fissures filled with mineral tar. If amendment does not speedily ensue, a dressing of calomel should be substituted for the tar several times a week. Ragged or loose portions of the frog may be removed by the knife or scissors.

Thuanus. See Thou, de.

Thucydides, the great historian of the Peloponnesian war, born in the deme Halimus most probably in 471 B.C., was the son of Olorus and Hegesipyle, and was related to Miltiades and Cimon. It is probable that his literary model was Antiphon, and that he was influenced in his views on philosophy by Anaxagoras. Certain it is that, Athenian as he was, of good family, and resident in the most cultivated community in Greece, he must have known Sophocles, Euripides, Aristophanes, Phidias, Protagoras, Gorgias, and possibly Herodotus and Æschylus. He was further possessed, either by inheritance or by acquisition through marriage, of gold-mines in that part of Thrace lying opposite the island of Thasos. We know from himself that he was one of the sufferers from the terrible plague of Athens, and also one of the few who recovered. He held military command, and he had under him an Athenian squadron of seven ships at Thasos, 424 B.C., when he failed to relieve Amphipolis, which fell into the hands of Brasidas. Condemned to death as a traitor, he took refuge in exile and retired to his Thracian estates. His exile enabled him, as he tells us, to associate with the Peloponnesians quite as much as with the Athenians; and he probably spent some time also in Sicily, as we may infer from his minute descriptions of Syracuse and its neighbourhood. According to his own account, he lived in exile twenty years, and probably returned to Athens after the destruction of its walls, in 404. How or when he died is unknown; but he did not live long enough to revise book viii. or to bring his history down to the end of the war.

If Herodotus was 'the father of history,' Thucydides was the first of critical historians, and no better account of his methods can be given than is contained in his own words: 'Of the events of the war I have not ventured to speak from any chance information, nor according to any notion of my own; I have described nothing but what I either saw myself or learned from others, of whom I made the most careful and particular inquiry. The task was a laborious one, because eye-witnesses of the same occurrences gave different accounts of them, as they remembered or were interested in the actions of one side or the other' (i. 22). There is hardly a literary production of which posterity has entertained a more uniformly favourable estimate than the history of Thucydides. This high distinction he owes to his undeviating fidelity and impartiality as a narrator; to the masterly concentration of his work, in which he is content to give in a few simple yet vivid expressions the facts which it must have often taken him weeks or even months to collect, sift, and decide upon; to the sagacity of his political and moral observations, in which he shows the keenest insight into the springs of human action and the mental nature of man; and to the unrivalled descriptive power exemplified in his account of the plague of Athens, and of the Athenian expedition to Sicily. Often, indeed, does the modern student of Greek history share the wish of Grote, that the great writer had been a little more communicative on collateral topics, and that some of his sentences had been expanded into paragraphs, and some of his paragraphs into chapters. But this want cannot have been felt by the contemporaries of Thucydides, while the fate of other ancient historians warns us that had his work, like theirs, been looser in texture, or less severely perfect, it would not have survived, as it has done, the wearing influence of time, or remained, in its own language, the *ktema es aei*—the 'possession for ever'—it has proved to the world.

It has been reserved for the 19th century to impeach the credibility, depreciate the matter, and to condemn the style of Thucydides. As these indictments, however, usually conclude with

the statement that Thucydides remains nevertheless the greatest of historians, they might here be passed over in silence were it not in the first place that they serve to show that Thucydides' fame is proof against the solvents of modern criticism, and next that they help us to a more complete understanding of the qualities which have given to Thucydides' work such a wonderful hold over the intellects and imaginations of all his readers and all his critics. The attacks on Thucydides' credibility have proceeded from Germany (see Müller Strübung in *Jahrb. f. Phil.* 131, 289 ff., and his *Aristophanes und die historische Kritik*, with Lange's reply in the *Jahrb. f. Phil.* 135, 721–748, and Classen's introduction to Thucydides, v., and Strübung's rejoinder *Thuk. Forschungen*), but have met with little acceptance there, and have found only one English-speaking follower, Professor Mahaffy. The most serious outcome of the discussion seems to be that Thucydides' knowledge of the topography of Platææ was defective, and that his account of the siege is consequently in accordance with the situation rather as he conceived it than as it actually was. But, even if we accept this application of the methods of modern criticism, it must not be imagined that those methods have all the same tendency. On the contrary, the actual treaty which Thucydides quotes in v. 47 has been discovered of late years, and confirms the accuracy and truth of the historian in a most unexpected and startling manner. The exact amount of accuracy or inaccuracy in Thucydides' account of the siege of Platææ is matter of opinion; his accuracy in the matter of the treaty is not—it is beyond dispute. But, after all, it is not by tests such as these, welcome as they are, that we can form an adequate opinion on the credibility of Thucydides. As an Athenian comedian remarks, we do not believe a man because he takes an oath—we trust the oath because we believe in the man. And so we believe in Thucydides not because we have external tests to apply (for we have not enough), but because the universal experience of all who read him is a feeling of conviction that his intention was to speak the truth, as far as he could ascertain it. This conviction is ultimately due to the fact that in the man's work we are brought directly into touch with the man, and we judge his character as we judge that of any acquaintance whom we know in the flesh. No man can devote himself for twenty-seven years to composing a work without putting a good deal of himself into the work, or without writing his character down in it—unconsciously but none the less legibly. What then are the qualities of character which impress the reader of Thucydides? In the first place, his impartiality. This is a quality unknown to Latin historians for instance. Tacitus will not admit that the Romans were ever defeated—the result was, at most, indecisive—even though the subsequent movements of the troops, as described by himself, clearly show that the Romans lost. Thucydides, on the other hand, though an Athenian, never extenuates even the mistakes of the Athenians; and though himself banished by them, sets down naught in malice against them. Next, the reader feels that Thucydides strove—and that always—to ascertain facts, and to put down as facts nothing but facts. This conviction is forced on one in many ways, some of which are palpable enough to admit of being clearly indicated. To begin with, there is the fact that, when in search of a subject, Thucydides did not, like all other historians before him, choose a period of ancient history, which, being ancient, must be based on vague hearsay or dim tradition. He preferred contemporary history and events which he himself witnessed in part, while he could obtain the evidence of eye-witnesses for the remainder. Nor did he wait until the conclusion of the war before setting about his task; from the very beginning he began collecting his facts. Next, his history is not designed to prove or illustrate any theory. He himself, in the passage quoted above, disclaims all attempt to adapt facts 'to any notion of his own;' and it is evident that beginning to write, as he began, at the commencement of the war, when its course and its issue were yet in the future, he could not have designed to bring its history into conformity with any pre-conceived or *a priori* theory. Herodotus, writing the history of the past, was in a position to trace the finger of destiny in what had happened, and to explain history by means of final causes. But Thucydides, when he undertook to record the present, thereby deliberately elected to confine himself to efficient causes. This preference for efficient causes and for 'scientific' history, in the best sense of the term, is intimately connected with the 'positive' nature of his history—that is to say, with his perpetual endeavour to record facts and to distinguish them from inferences drawn from facts. A clear consciousness of this difference is involved in one of the most characteristic features of his history—that is, the marked difference between his narrative and the speeches which he introduced into it. The former contains facts and facts only, facts stated with a precision and objectivity which—e.g. in his description of the symptoms of fever in sufferers from the great plague—have been the marvel of all subsequent generations, and the greatest marvel to those who by special professional knowledge are competent to judge. The speeches, on the other hand, are not what the speakers actually said—but of this Thucydides warns the reader at the beginning, showing clearly at once the distinction he drew between facts and inference, and his anxiety that the reader should realise the distinction. In fine, most of the untruth in this world is due not to deliberate perversion, but to the simple fact that so many people are quite unconscious what truth is. When then we find that Thucydides had a conception of historic truth and fact such as 2000 subsequent years have been unable to improve, and that he strove strenuously all his life to live up to that conception and write up to it, we can well understand that even 19th-century criticism acknowledges itself incapable of shaking his credibility.

As for the subject of Thucydides' history, if the Peloponnesian war was not a matter of importance in universal history, it was at least not Thucydides' fault that he was not contemporary with some more important war. But we may beg leave to doubt whether the Peloponnesian war was of inferior interest for the fortunes of mankind. Had it not been for the exhaustion it induced, Greece would not have succumbed to the Macedonian, and consequently Alexander's conquests would never have spread Greek culture over the ancient world. But, apart from this, Thucydides' history is the history of the effects of empire on an imperial state; and, as such, will always be of enthralling interest to citizens of sovereign communities. Finally, Thucydides' style, criticised by Dionysius and condemned by Mure, is in the speeches difficult beyond all possibility of dispute. To throw the blame of this obscurity on the unformed condition of Attic Greek at the time when Thucydides wrote is warrantable indeed, but is no adequate defence. To point, on the other hand, to the tract *On the Athenian Polity* as proof that Attic prose could be translucent in Thucydides' time is beside the point, for Attic, as is well known, could only be written well by those who lived continuously in Athens, and Thucydides was exiled for many

a year. But, in truth, the question whether it is Thucydides or the literary age in which he lived that is to be blamed for his obscurity is a wholly irrelevant question. Obscurity, whatever be its cause, is a crime in a writer. But it is a crime which carries its own punishment, for it diminishes the number of an author's readers. The exact amount of criminality is not to be determined on any abstract principles or by the exercise of any mysterious 'taste:' it admits of one simple practical test—viz. has the obscurity of his style (in so far as it exists), as a matter of fact, prevented him from attaining fame? In the case of Thucydides it has had no such effect, as all testify. People will not read a difficult author if there is an easier one out of whom they can get as much. That Thucydides has, in spite of his difficulty, always been read is in itself sufficient testimony that there is no other historian to rank with him.

The best editions are in Latin that of Poppo (11 vols. Leip. 1821-40), in German that of Classen (2d ed., 8 vols. Berlin, 1870-78), and in English—at least for historical illustration—of Arnold (3 vols. Oxford, 1830-35). The best English translation is by Professor Jowett (with a commentary, 2 vols. Clarendon Press, 1881); that by the Rev. Thomas Dale is also good (2 vols. 1848), as is that of the speeches by H. M. Wilkins (2d ed. 1873).

Thugs (from the Hindustani *thaga*, 'deceive'), the name for a religious fraternity in India, which, professedly in honour of the goddess Káli, the wife of Siva, was addicted to the committal of murders, and lived upon the plunder obtained from its victims. Banding together in gangs, they assumed the appearance of ordinary traders, and, insinuating themselves into the confidence of unsuspecting fellow-travellers, killed them by strangling (whence they were often called *phansigars*, 'stranglers'), or by poisoning with datura (see THORN-APPLE). They were bound together by bloody oaths, and carried on systematic assassination on a large scale. They considered their murders pious rites, and their profession more than respectable. The confraternity appears to have come into existence under the early Mohammedan rulers of India; and though the English government frequently apprehended Thugs, it was reserved for Lord William Bentinck, assisted by Captain Sleeman, to adopt such vigorous measures as practically extirpated thuggee (*thagi*). In 1826-35 no fewer than 1562 Thugs were apprehended—mainly by help of accomplices turning informers—of whom 382 were hanged, and most of the rest transported or imprisoned for life. Thuggee by poisoning was still carried on long after strangling was a thing of the past.

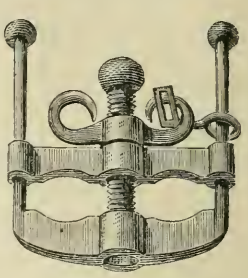
See Col. Meadows-Taylor's graphic tale, *Confessions of a Thug* (1839; new ed. 1879); Capt. Sleeman's *Report* (1840); Hutton's *Thugs and Dacoits* (1857); for thuggee in 1867, Hervey's *Some Records of Crime* (1892); and for their jargon, Sleeman's *Ramaseeana* (1836) and Yule and Burnell's *Hobson-Jobson* (1886).

Thuja. See ARBOR VITÆ.

Thule, the name generally given by the ancients to the most northerly part of Europe known to them, of which their want of knowledge was eked out by the imagination. According to Pliny it was an island in the northern ocean, discovered by the navigator Pytheas of Massilia, who reached it after six days' sail from the Orcades. Most probably Pytheas followed closely the eastern coast of Great Britain, and heard exaggerated reports of the groups of islands farther north—the Orkneys and Shetlands, perhaps even Iceland—which he thought lay close to the Arctic Circle. The usual Roman phrase was *Ultima Thule*.

Thumb, TOM. See DWARFS.

Thumbscrew, or THUMBIKINS, an instrument of torture for compressing the thumb, largely made use of by the Inquisition in Spain, and also occasionally used in England, when examination by torture was practised there. It was much in use during the brutal persecutions of the Covenanters in Scotland, and the famous Carstares (q.v.) was tortured thus for an hour and a half at Holyrood to obtain the secrets of the Argyll party.



Thumbscrew.
(In Ant. Mus., Edinburgh.)

Thun, a picturesque and ancient town of Switzerland, 17 miles SSE. of Bern by rail. It stands on the Aar, hardly a mile from the Lake of Thun (12 miles long, 2 broad; greatest depth, 1844 feet), out of which the river rushes past the town in a stream of crystal clearness. A 12th-century castle and a venerable church are the chief buildings. Pop. 5507.

Thunder. See LIGHTNING. Celts (see STONE AGE) are sometimes called thunderbolts, from a notion that they are meteoric stones; and for a like reason Belemnites (q.v.) are called thunder stones. For the Thundering Legion, see AURELIUS.

Thunder Bay. See SUPERIOR (LAKE).

Thurgau (Fr. *Thurgovie*), a frontier canton in the north-east of Switzerland. Area, 381 sq. m.; pop. (1898) 111,204, of whom two-thirds are Protestants. The surface, unlike that of the other cantons of the country, is undulating or hilly, but nowhere mountainous, the chief height being the Hörnli in the extreme south, 3722 feet. The principal river is the Thur, which, flowing WNW. through a broad fertile valley, joins the Rhine in the canton of Zurich. Capital, Frauenfeld.

Thurifer (Lat. *thus*, 'incense,' and *fer-*, 'to carry'), the attendant in the Roman Catholic Church, at solemn mass, vespers, &c., whose duty it is to carry the *thurible*, or incense-vessel, and either to minister incense himself or to present the thurible to the officiating priest. The office is one of those which belong to the so-called 'minor order' of *Acolyte*.

Thuringia (Ger. *Thüringen*), the name still borne by that part of the ancient Saxon area which is generally bounded by the Werra, the Saale, and the Harz Mountains; the Thuringian states being the minor Saxon Duchies (q.v.), the two Schwarzburgs, the two Reuss principalities, and small parts of Prussia, Saxony, and Bavaria. The district got its name from the Thuringian tribe of Germans, who were found inhabiting it in the 5th century. The Thuringian Forest (*Thüringer Wald*) is a series of wooded mountain-ridges occupying great part of this area. It is some 70 miles long, and belongs to the Sudetic system.

Thurles, a town in county Tipperary, Ireland, situated on the river Suir, 87 miles SW. of Dublin by rail. Four miles distant is the beautiful 14th-century ruin of Holy Cross Abbey. Thurles has a (classical) Roman Catholic cathedral, built at a cost of £45,000, the seat of the archbishopric of Cashel. Pop. 4850.

Thurlow, EDWARD, BARON, was born a clergyman's son in 1732, at Bracon-Ash in Norfolk. He was sent to Canterbury grammar-school, whence he passed to Caius College, Cambridge. Here he was as insolent and insubordinate as at school, and was sent down in 1751 without a degree. He at once entered at the Inner Temple, and was called to the bar in 1754. He was a

fellow-pupil in a solicitor's office with the poet Cowper, and still affected idleness, although in reality he worked hard to make himself a good lawyer. His lofty stature, strongly marked features, dark eyes, bushy eyebrows, and look of self-possession led every one with whom he came in contact to attribute to him qualifications he really did not possess—'no man,' said Fox, 'ever was so wise as Thurlow looked.' An accidental meeting at a coffee-house with the Scotch solicitors in the great Douglas case led to his employment in it as junior counsel, and to his acquaintance with the members of the Douglas family. One of them, the Duchess of Queensberry, by her influence with Lord Bute obtained for him in 1761 the rank of King's Counsel. Soon after this he acquired a still higher reputation by his speech in the Douglas Peerage case—the greatest effort of his life. In 1768 he was returned for Tamworth, and became a zealous supporter of Lord North; in March 1770 he was made Solicitor-general, and the year after Attorney-general. He gained the special favour of George III. by the violent zeal he displayed in supporting his American policy. In 1778 he became Lord Chancellor and Baron Thurlow, and such was his influence with the king that he was allowed contrary to all precedent to retain the office under the Rockingham administration. He caused great embarrassment by opposing all the measures brought in by that government. Under the coalition ministry of Fox and North he was compelled to retire, but continued a vigorous opposition, and was restored as Chancellor on Pitt's accession to power. For a time he supported the government; but, relying again on the support of the king, he once more began, first secretly, then openly, to undermine the power of his colleagues. Pitt then intimated that he or Thurlow must retire, and the king, without any hesitation, consented to his removal (1792). Thurlow at once sank into obscurity. He amused himself in reading the Latin and Greek classics with his nephews, and spent much of his time in visiting and receiving visits. He died at Brighton, September 12, 1806. Thurlow was vulgar and arrogant, his profanity and immoralities notorious. Lord Campbell says he can find nothing recorded of him to justify the great reputation for ability he had among his contemporaries, and ascribes it chiefly to his assuming manner; but it should be remembered that he had no Boswell to record his talk, and that it was this that was most admired. It was of no ordinary man that Johnson said, 'I would prepare myself for no man in England but Lord Thurlow. When I am to meet him, I should wish to know a day before.'

Thurn and Taxis, PRINCES OF, a princely house with high rank, hereditary dignities, and vast possessions in Austria, Bavaria, Würtemberg, Prussia, and Belgium, the heads of the two main lines being resident at Ratisbon and at Laucin in Bohemia. Descended from the Della Torre of Milan (whence the first part of their name), with a castle of Tasso or De Tassis (whence the second), members of this house have been distinguished in connection with posts. One established posts in Tyrol in 1460; another, ennobled in 1512, established the first post between Vienna and Brussels in 1576. His descendant became in 1595 grand-master of the posts of the Holy Roman empire, and secured the right of carrying on the posts of the empire which extended from Hamburg to Rome, and from Paris to Vienna, for himself and his heirs as a hereditary privilege. In 1681 the principality of Thurn and Taxis in the Netherlands was conferred on the head of the house; and in 1698 the princely rank and title were made hereditary, and passed to all members of the house. The postal privileges were gradually limited by the governments of the various countries; but it was not till 1867 that Prussia secured by treaty with the family the abolition of the monopoly.

Thurot, FRANÇOIS, was born at Nuits in Côte d'Or, son of a petty innkeeper, 22d July 1726. He grew up a reckless and violent lad, and served on a privateer, but was captured and kept a year in Dover prison. He managed to seize a small boat, and crossed the Channel with a pair of sculls and his shirt as a sail. The Maréchal de Belle-Isle hearing of the exploit enabled him to study navigation, and Thurot, again joining a privateer, rose so rapidly that by 1748 he was able to fit out a merchant-ship. He next spent a few years in England, mostly in London, betwixt music, mathematics, and dissipation, varied by smuggling and perhaps piracy; and in 1753 his ship was seized by the English. The outbreak of war recalled him to France. He was given the command of a squadron of two frigates and two sloops, with which he scoured the Channel, cruised along the east coast of England and Scotland, frightening terribly the townspeople of Banff (5th October 1757), and fought a brisk action with two English frigates at the mouth of the Forth. In October 1759 he again weighed from Dunkirk with a squadron consisting of four frigates, with 1200 soldiers under command of Flobert, and made his way to Lough Foyle, intending a descent on Londonderry. High gales made it impossible to enter, whereupon he crossed to Islay for supplies, and then sailed for Belfast Lough, intending to make a dash on Belfast. Flobert ruined the plan by insisting on attacking and taking Carrickfergus first (21st February 1760), but refused to move on Belfast. The delay had given time for three English frigates of Hawke's fleet to come up; and Thurot fought an hour and a half, till he was struck down, on which his ship hauled down her colours. See Prof. J. K. Laughton's *Studies in Naval History* (1887).

Thursday Island, one of the smallest of the group of the Torres Straits islands, north of Cape York, and belonging to Queensland. It has an excellent harbour, Port Kennedy, which is a telegraph station, and a station for several lines of steamers. The island is a centre of the pearl and trepang fisheries.

Thurso, a burgh of barony and seaport of Caithness, at the mouth of the Thurso River, by rail (1874) 21 miles NW. of Wick and 154 NNE. of Inverness. It is pleasantly situated and handsomely built—except in the older quarter—and has six churches, a town-hall (1870), capital bathing, &c. The harbour at the mouth of the river had got silted up; but extensive improvements were carried out in 1891-92, when also a good pier at Scrabster was extended, on the west side of the bay, where steamers regularly call. The rock scenery around the town is very fine. Paving-stones are prepared and exported, and live-stock and grain shipped. The self-taught geologist, Robert Dick (1811-66), was a baker here from 1830. Pop. 3930.

Thyatira. See AK-HISSAR.

Thylacine (*Thylacinus*), the largest of the extant predaceous marsupials, represented by one species (*T. cynocephalus*), now restricted to Tasmania, and in process of extermination at the hands of the sheep-farmers, whose folds it is wont to ravage. It is somewhat smaller than a wolf, has a dog-like muzzle, a long tapering tail, and is grayish brown in colour, with black cross bands on the hind part of the back and loins. It is very active and fierce, and is popularly called a 'tiger,' a 'wolf,' or a 'hyæna.'

Thyme (*Thymus*), a genus of humble, half-shrubby plants, of the natural order Labiatæ, having a two-lipped calyx and four diverging stamens. Garden Thyme (*T. vulgaris*) is 6 to 10 inches high, with narrow, almost linear leaves, and whitish or reddish flowers, which grow in separate whorls, six in a whorl. It is a native of Spain and Italy, is very commonly cultivated in gardens on account of its fragrance, and was introduced into Britain about 1548, or very probably at an earlier date. Wild Thyme (*T. Serpyllum*) has a procumbent stem with many branches, forming tufts, low and dense, a few inches to a foot wide, oval leaves and purplish flowers, arranged in whorls, which are united in a head. It is abundant on hills and mountains in Britain and in all parts of Europe and the north of Asia. It is less fragrant than garden thyme, but both species contain an aromatic essential oil. The flowering branches (*Herba Thymi* and *Herba Serpylli*) are used in medicine as a powerful stimulant, and those of garden thyme are also used in cookery for flavouring. The Lemon Thyme, or Lemon-scented Thyme, of our gardens, is regarded as a variety of *T. Serpyllum*. It is generally of still lower growth than the common garden thyme. No species of thyme is indigenous in America. Thymol, an antiseptic phenol, is obtained from oil of thyme by distillation.

Thymeleaceæ, a natural order of plants, of which the Mezereon and Spurge Laurel (see DAPHNE) are familiar examples. This order consists chiefly of shrubs, with a few herbaceous plants, and contains about 300 species, natives chiefly of the warmer temperate countries. Poisonous properties prevail in the order. The bark is in general very caustic.

Thymus Gland, a gland which begins to form at an early period of embryonic life, and, commencing as an epithelial ingrowth from the throat, extends from the neck right into the chest, where it is placed anteriorly in the mediastinum. It continues to grow after birth, but when adult life is reached it shrivels to an inconsiderable mass. When examined microscopically it is seen to consist of a tissue very similar to that of a lymphatic gland, and in this tissue are (Hassall's corpuscles) nests of concentrically arranged epithelial cells, probably the remnants of that epithelium of which the gland, at an earlier period, was almost entirely composed. The gland when fully developed is what may be called a blood-gland, for it is connected with the rest of the system by blood-vessels and nerves alone, unlike the liver or kidneys, which are provided with ducts through which their secretion is carried away. Regarding the function of this gland almost nothing is known. It probably is concerned, in some way, in altering the chemical or cellular structure of the blood. Numerous extractives, such as leucin and tyrosin, are found normally in it, and from it a substance can be extracted which acts as a powerful blood coagulant. It is possible, too, that in its substance the blood-cells may to some extent be produced. Its early development and rapid disappearance suggest that its chief activity is called into play during that period of life when growth and tissue formation are most active.

Thyroid Gland, a gland which arises in the early human embryo as an ingrowth from the lower part of the pharynx. This extends down to the lower part of the neck, and its original connection with the pharynx is lost. In the adult it is found as a bilobed structure on either side of the windpipe, and joined in front of this tube by an isthmus of gland-tissue. It is ensheathed in connective tissue, which passes into its interior, supporting and separating from one another the delicate structures within. The gland is a ductless gland, but is richly supplied by blood-vessels, which ramify around the tiny glandular capsules of which it is composed. If a section of the gland be examined with the microscope, it is seen that there is a vast number of tiny spherical cavities lined by short cubical cells; and within and entirely filling these cavities, there is a structureless-looking and very insoluble jelly. In the walls of the little cavities the dense Anastomosis (q.v.) of blood-vessels is seen. We are very much in the dark as to the meaning of this structure, and the parts played by the epithelial cells and the jelly in the function of the gland. That the gland is important is proved by the injurious effects which follow its removal, and by the fact that in connection with several diseases the gland is swollen and altered in structure. In some animals, the dog for instance, the jelly within the capsules is often found to contain red blood-corpuscles. Sometimes large numbers of these are seen, and in other cases the blood pigment (hæmoglobin) may be seen beautifully crystallised out in the jelly. That the gland has something to do with the blood seems very evident, but what part it exactly plays is not yet certain. If the gland be excised, in some animals, curious mucous degenerations are found to follow the operation, and a tendency to mucous deposits and tumours seems to be associated with disease of the gland. Some have thought that this points to some action of the gland in the formation of mucous within the body, but about this little is known. If the gland is excised nervous symptoms and muscular tremors may be produced, and it has been supposed that in some way the gland exercises an influence upon the blood-flow through the brain. The gland is frequently enlarged, forming the condition termed Goitre (q.v.). This enlargement may be due to a great increase in the number of blood-vessels, or we may find that it is due to the enlargement of the little capsules which normally contain the thyroid jelly. These capsules run together so as often to form large cysts full of jelly. Associated with this enlargement one often finds nervous symptoms and disturbances of the circulatory system, and the curious condition termed cretinism. In exophthalmic goitre we have a peculiar protrusion of the eyes associated often with an unimportant-looking swelling in the neck. See also CRETINISM, MYXŒDEMA.

Thysanura, an order of wingless insects of small size. They undergo no metamorphosis. The abdomen usually bears peculiar structures, which seem to be abortive limbs, and the name Thysanura or bristle-tails refers to terminal appendages which are sometimes long and hairy. See SPRING-TAILS; and Sir John Lubbock, *Monograph of the Collembola and Thysanura* (Lond. 1873).

Tian-shan ('Celestial Mountains'), a great mountain-system, consisting of several ridges, mostly parallel, in central Asia, extends from the Pamir (q.v.) to the north of the Tarim depression in Turkestan, and occupies the frontier region between Russian territory on the north and the Chinese dominions to the south. See ASIA, Vol. I. p. 486.

Tiara.

Tiara, the triple crown of the pope, which is considered to be symbolical of his temporal, as the keys are of his spiritual authority. It is composed of a high cap of gold cloth, encircled by three coronets, with a mound and cross of gold on the top. The original papal crown consisted of the cap alone, the word *tiara* having long been

synonymous with *mitra*. It is not certain when the first and second princely crowns were added, the current statement that it was Boniface VIII. who assumed the second having been disproved by Hefele from old representations of Innocent III. Urban V. (1362–70) added the third.

Tibbu, a people of the Sahara (q.v.)

Tiber (Ital. *Tevere*, Lat. *Tiberis*), the chief river of Central Italy, and the most famous in the peninsula, rises in a dell of the Tuscan Apennines (province Arezzo), about 11 miles N. of the village of Pieve Santo Stefano. Its course until it reaches Perugia is south-south-east; thence, as far as Rome, it pursues, along an irregular zigzag line, a southern direction; but when it enters the plain of the Campagna it curves south-south-west, and enters the Mediterranean by two branches, which enclose the Isola Sacra. Of these the northern, the Fiumicino, alone is navigable; the Fiumara is silted up with sand. The entire course of the river is about 260 miles—only 145 direct from source to sea. The most celebrated towns on or near its banks are Perugia, Orvieto, Rome, and Ostia; and its chief affluents are the Nera with the Velino and Teverone or Aniene (*Anio*) from the left, and the Paglia with the Chiana from the right. In its upper course it is rapid and turbid, and of difficult navigation. It is navigable for boats of fifty tons to the confluence of the Nera, 100 miles from its mouth, and small steamers ascend to within 7 miles of that point. The Tiber is supplied mainly by turbid mountain-torrents, whence its liability to sudden overflowings of its banks; even the oldest Roman myth, that of Romulus, being inseparably associated with an inundation. Its waters, too, are still discoloured with yellow mud, as when Virgil described it—*Vorticibus rapidis et multa flavus arena*. See ROME, pp. 784, 786; and W. Davies, *The Pilgrimage of the Tiber* (2d ed. 1875).

Tiberias. See GALILEE.

Tiberius, the second emperor of Rome (14–37 A.D.), whose real character remains to this day among the enigmas of history. Tiberius Claudius Nero was the son of T. Claudius Nero and of Livia, and was born 16th November 42 B.C., four years before her complaisant husband yielded Livia to the triumvir Octavianus. He was nine when his father's death transferred him to the tutelage of his step-father, and eleven when that step-father became the undisputed master of the Roman empire. Being now a member of the imperial household, he received a careful education and the same public honours as were paid to the nephew and grandsons of Augustus. At nineteen he filled the quæstorship, became prætor at twenty-five, and consul at twenty-nine. But almost the whole of his first twenty years of manhood were spent in the camp—in Spain, Armenia, Gaul, Pannonia, and Germany. He had the honour of bringing back the standards lost with Crassus; in 15 B.C. he co-operated with his brother Drusus in subduing the Rhæti and Vindelici; warred with the Pannonians (12–9), and in the campaign that followed the death of Drusus traversed Germany between the Rhine and the Elbe. The young Marcellus, nephew of Augustus, had died in 23; Agrippa, son-in-law of Augustus, died suddenly in 12, leaving only two boys of eight and five between the step-son and the succession. Tiberius was now compelled (11) by Augustus to divorce his much-loved wife Vipsania Agrippina, daughter of Agrippa by his former wife Pomponia, in order to marry Agrippa's widow Julia, the profligate daughter of Augustus. Hardly was he married than he was sent to crush a revolt in Dalmatia and Pannonia; Drusus died in 9, and Tiberius marched at the head of his funeral train on foot in mid-winter from the Rhine to Rome, returning immediately to the wars in Germany, for the successes in which he was rewarded with the full *triumph* (9) and other honours. But suddenly in 6 he retired to Rhodes, where for seven years he gave himself to study and to astrology. The open profligacy of the wife who had been forced into his arms was perhaps the most powerful reason which drove him from Rome to the displeasure of the emperor. Before his return (2 A.D.) the infamous Julia was banished to Pandataria (2 B.C.), and within the two years after the deaths of both the young princes Lucius and Gaius (2 and 4 A.D.) paved the way for the adoption of Tiberius as heir to the imperial dignity, the third grandson, Agrippa Postumus, being at once too young and too incompetent for command. He was now formally adopted by Augustus. Tiberius spent the next seven years in active service in north Germany against Marobodnus, in quelling formidable insurrections in Pannonia and Dalmatia, and finally in securing the frontier and taking vengeance upon the enemy who had annihilated the army of Varus in 9 A.D. Along with Germanicus he made two marches into the heart of Germany (9–10), returning to enjoy a splendid triumph (12).

On the death of Augustus at Nola in 14 Tiberius succeeded without opposition. He was fifty-six years old, taciturn, impenetrable, suspicious, beloved by none, yet respected by all for his gravity of demeanour and the reputed severity of his virtue. The first eight years of his reign are treated by Tacitus in the first three books of his *Annals*, and are reluctantly admitted to have been marked by just and moderate government, respect for the laws, frugality, and care for the interests of the provincials. The whole is set down to sustained hypocrisy—a theory of human character hardly to be accepted without hesitation. During this period only twelve state trials for *majestas* ('high treason') are recorded. The next period of the reign, treated in the fourth book of Tacitus, covers the six years 23–28. As yet, according to Tacitus, the evil impulses of Tiberius were restrained by the influence of his still surviving mother. The number of trials for *majestas* has grown to twenty, the espionage of informers has also increased as well as the severity of sentences. His minister Sejanus has grown to vast influence through playing for his own ends upon the morbid suspiciousness of his master. For the last period of the reign, covering eight years and a quarter, we miss the lost fifth book of Tacitus for the years 30–31. The sixth book opens near the close of the year 31, and brings the story of Tiberius through the six years' reign of terror in which 80 to 100 lives perished mostly by direct mandate of the prince down to its shameful close in the foul debaucheries, the gloom, and the insanity of Capreæ.

Such is the gloomy drama of the reign of Tiberius in the splendid pages of Tacitus. It only remains to be seen what are the historically reliable elements of the story. In general terms it may be said that the facts are mainly trustworthy, if the motives imputed cannot always be accepted. There is no doubt that for some years Tiberius took, or affected to take, little active part in public affairs, and indeed throughout one of the deepest principles in his Roman nature was regard for constitutional forms. But his care for the real interests of the provincials was an element new to Roman politics, and showed a foresight and statesmanship to which Augustus had not risen. The only important open changes he made were the permanent encampment of the imperial guard close to the city walls, and the abolition of the old *comitia*, the election of public officers being

transferred to the subservient senate. But the one fatal feature of the reign was the institution of the *judicia majestatis*, which grew up out of the slavish adulation of the senate, the deep suspiciousness of the emperor's own nature, and the subtle manner in which this was fed by Ælius Sejanus, commander of the prætorian guards. *Delation*, or denunciation of individuals by informers, soon grew to great proportions, and men breathed in a constant atmosphere of terror. In 26 Tiberius left Rome for Campania, and the year after took up his abode in Capreæ, where Suetonius tells us he wallowed in brutish sensualities. He had given his entire confidence to Sejanus, leaving him the whole control of government; but at length awakened to the ambitious designs of his minister, he struck him down without hesitation (31). Macro, the successor of Sejanus, had all his vices without his talents, and so the state of affairs was even worse than before. The murder of Agrippa Postumus in 14, the mysterious death of Germanicus in the East (19), the poisoning of Tiberius' own son Drusus by Sejanus (23), the banishment of Agrippina and the untimely death of her young sons Nero and Drusus (31 and 33) were some of the dark tragedies that befell the house of Augustus under the reign of Tiberius. In his last years the emperor's mind was darkened by gloom, superstition, and perhaps insanity. The famous words Tacitus has preserved of a letter to the senate (*Ann.* vi. 6) seem like a momentary flash of revelation of more than mere remorse: 'May all the gods and goddesses destroy me more miserably than I feel myself to be daily perishing, if I know at this moment what to write to you, senators, how to write it, or what, in short, not to write.' On the 16th March 37 his worn-out frame fell into a sort of lethargy, in which he was suffocated by Macro to prevent his recovery.

The original authorities are Tacitus, Suetonius, and Velleius Paterculus. The first admits that the history of Tiberius was 'falsified, while he reigned, through terror, and written after his death with the irritation of a recent hatred.' Whether the portrait he has himself constructed with such consummate literary art is psychologically possible or no, there can be no doubt at least that his own feeling was too bitter to permit of a judicial estimate. Suetonius as a historical writer shows no discrimination in choosing his materials, and his fondness for scandal and gossip was far stronger than his zeal for truth. Velleius Paterculus had served under Tiberius, but his overdone panegyric gives the fatal suggestion of flattery. Dion Cassius again wrote nearly two centuries after Tiberius, and was wise enough to follow Tacitus pretty closely, the character of Tiberius being a study much too complex for his powers of analysis. Dean Merivale in his *History of the Romans under the Empire* defends Tiberius with moderate zeal, believing him at least the victim of much ancient misrepresentation; Professor Beesly in a preposterous paradox (*Catiline, Clodius, and Tiberius*, 1878) repudiates the whole account by Tacitus as a deliberate and malignant libel. M. Dŭruy is measured in commendation in his *History;* M. Boissier sums up against him in *L'Opposition sous les Césars* (1875); the Comte Champagny, with vehement invective, in *Les Césars*.

Besides these, see Mommsen's fifth volume of the *History of Rome*, translated as *The Roman Provinces from Augustus to Diocletian* (1886); L. Freytag, *Tiberius und Tacitus* (Berl. 1870); T. Stahr, *Tiberius* (2d ed. Berl. 1873); Pasch, *Zur Kritik der Geschichte des Kaisers Tiberius* (Altenburg, 1866); and Hermann Schiller, *Geschichte der Römischen Kaiserzeit* (Gotha, 1883); also the excellent essay by Henry Furneaux prefixed to his edition of the *Annals* (vol. i. 1884).

Tibet, or THIBET, is the European name of a country in central Asia, lying between China and India. The native name is Bod or Bodyul. Tibet is enclosed between the Kuen Lun and the Himalaya mountains. These chains run eastward from a mountain knot at the southern extremity of the Pamir highland, and continue to diverge from each other till they reach the meridian of Lhassa, when they slightly draw nearer on the east and south-east, where Tibet is bounded by ranges which separate it from China and Indo-China. It is thus surrounded on all sides by mountains, the area so enclosed exceeding in extent 700,000 sq. m., or being eight times the size of Great Britain. Tibet is the loftiest region of such extent on the globe. Its tablelands vary in height from 17,000 to 10,000 feet. It has been estimated that their average height is that of the summit of Mont Blanc; this may be a slight exaggeration, but it impresses on the memory the great elevation of Tibet, the most important fact in its physical geography. The tablelands are loftiest in the west and north, whence they slope gradually to the south and east. Bonvalot certified to the existence of volcanoes. The lowest lands in Tibet are the grooves in which the Indus runs westward and the Sanpo eastward to the bends where they turn to the south, cross the Himalayas, and descend into India. The mountain-girdle which surrounds Tibet has made it an obstacle across which conquerors from Mongolia could not enter India without making a long detour round its western extremity. Another consequence of these barriers has been that Tibet has remained to the present day the region of the globe least known to geographers.

Tibet is divided into provinces equal in extent to European states. These are (1) Chaidam (Tsaidam), a name sometimes given to the country between the Nanshan and Alten-tagh chains and the Kuen Lun. It includes the Koko-Nur lake and the Chaidam marsh, and its cold and scanty pastures are frequented by nomads, among whom is the Tibetan race known as the Tanguts. (2) Katchi, also described as the great northern plain, a lofty region of steppes very little known, but crossed by a road from Kiria in Turkestan, and leading to the gold-fields of Thok-Jalung, one of the highest inhabited spots on the globe. (3) East Nari, including Khorsum and Dokthol, an elevated Himalayan country in which the Indus and Sanpo take their rise. It is a country of pastures with a few cultivated tracts. In it is the Lake Manasarowar, surface 15,000 feet high, a sheet of water sacred alike to Tibetans and Hindus. (4) West Nari, or Little Tibet, consisting of Ladakh (q.v.) and Balti, now dependencies of Cashmere (q.v.) and the Indian empire. (5) Yu-tsang, composed of the provinces of Yu and Tsang. It includes the valley of the Sanpo between the meridians of 87° and 92°, the most populous and important part of Tibet. The Sanpo becomes navigable at Janglache—elevation 13,600 feet. From thence boats formed of a framework of wood covered with hides descend the river. On reaching their destination after being unloaded they are taken down and conveyed by yaks back to the starting-point. Yu-tsang is traversed by a well-frequented road from east to west. The capital of Yu is Lhassa (q.v.); that of Tsang, Shigatze. (6) Kham, the province drained by the upper courses of the great rivers of China and Indo-China, which run in deep valleys, making it difficult to cross the country. Two great roads traverse Kham, connecting Lhassa with Darchiendo (Ta-chien-lu), the emporium of Chinese trade with Tibet. One is the shortest and official road. It passes through Litang (13,400 feet) and Batang (8150 feet) on the Yang-tse-kiang and Chiamdo, the capital of Kham, on the Mekhong, and over lofty passes into Lhassa. The commercial road crosses the rivers higher up, where the watercourses are less difficult and there is an abundance of pasture. Near Darchiendo the country seems to be independent alike of China and Tibet, and farther west is Darge, a district

described as rich and flourishing. Chiamdo and other parts of Kham are under the direct rule of China.

Tibet lies in the latitudes of Delhi, Cairo, Algiers, and Naples, but its inland position and elevation give it a cold, dry, and extreme climate. On the tablelands at an elevation of 14,000 feet the thermometer in May sinks to 7° F. below zero, and over the whole country an arctic winter prevails for five or six months. Owing to the dryness of the air it loses its conductivity, and the inhabitants, dressed in sheepskins, give out long electric sparks on approaching conducting substances. Flesh exposed to the air does not putrefy, but dries and can be reduced to powder. There is a very short but excessively hot summer, more especially in the valleys of the Indus and Sanpo, where the high temperature is more oppressive to Europeans than that of the Indian plains. The northern and western tablelands are without trees. They abound in steppes, in which pasture innumerable herds of wild animals—yaks, horses, asses, goats, antelopes, &c.—undisturbed by man. The pastures of the southern tablelands supply food to the flocks and herds of a large nomad population. Agriculture is confined chiefly to the valleys of the Indus and Sanpo, the grain chiefly grown being barley; the kitchen herbs and fruits of Europe are also cultivated. Agriculture and gardening are difficult arts in Tibet, and the irrigation and terrace cultivation necessary to secure even scanty crops are supposed to have sharpened the intelligence of the peasants and made them strong and laborious. The mineral products of Tibet are of high value, and include gold, silver, iron, copper, zinc, mercury, cobalt, borax, sulphur, &c. The Tibetans are good blacksmiths and cutlers; their chief industrial occupation, however, is the preparation of woollen cloth. They are active traders, and large caravans, in which yaks and sheep are the beasts of burden, are constantly traversing the country on their way to the great fairs in Tibet, and the entrepôts of the surrounding countries. At one time there was a busy commerce with India, but since Tibet became a Chinese dependency the passes have been closed. The most important commerce is in the hands of rich Tibetan and Chinese traders, who jealously watch anything likely to interfere with the existing great routes. Of the distribution of population in Tibet little is known. The most densely peopled part of the country is certainly the basin of the Sanpo, in which are the towns of Shigatze and Lhassa. The population is estimated at six millions.

The Tibetans are a Mongolic race, much more closely allied to the Burmese than to the Chinese or Mongols proper. They are broad-shouldered and muscular, and present a striking contrast to the weak-calved Hindus. They have Mongol features, but not in an exaggerated form. They are said to be intelligent, but without initiative; different views have been taken of their moral character, but on the whole they seem to be kindly and truthful. They are very fond of music and dancing. The Tibetans by race people nearly the whole of Tibet. A few nomads, Mongol and Turkish tribes, have penetrated into the northern steppes, and Chinese in large numbers have colonised the south-east.

In Tibet, owing to its isolation, some archaic customs survive. One of these is polyandry, the husbands of one wife being generally brothers. This form of marriage is almost universal among the poor, and seems to give rise to less domestic trouble than might have been expected. The rich are polygamists. Both systems check population. In Little Tibet, where monogamy has penetrated from the west, population increases rapidly. There exist in Tibet two religions: (1) the Bon or Bon-Pa creed, which is a development of Mongol Shamanism, and is the native religion; and (2) Lamaism (q.v.), a form of the Buddhism introduced from India. The Tibetan clergy are very numerous, there being, it is estimated, one monk for every family. Monasteries and convents are everywhere. In Tibet the performance of elaborate ceremonies is held to be more important than good works, and can only be carried out with the aid of the clergy, who are said to be avaricious, idle, and dissolute.

Since 1720 Tibet has been a dependency of China, which, however, interferes only with foreign and military affairs. Two imperial Chinese delegates reside at Lhassa, one, the amban, the superior of the other; Rockhill says his authority is really infinitesimally small, though he writes despatches as if master of the situation. Civil and religious government are left to the Tibetan clergy, as they were in the old Papal States. In theory supreme rule is in the hands of the Dalai Lama, the sovereign pontiff who resides at Lhassa. The Tesho or Bogdo Lama, who has an inferior spiritual power, resides at Shigatze. The Dalai Lama hands over the active duties of government to the de-sri or king, who rules with the assistance of four ministers. The Tibetan language as spoken differs much from the old written language; it has been losing its monosyllabic character. Books abound in Tibet, and every monastery has its library. The literature consists chiefly of translations from the Sanskrit, and of religious works.

The earliest date in Tibetan history which can be relied on as historical is 639 A.D., when the king Sbrong-tsan-Sgam-po introduced Buddhism from India, and founded Lhassa. His dominions extended from the Himalayas north to the Koko-Nur Lake. In the middle ages down to the 10th century the Tibetan country is said in the Chinese annals to have extended to the Gulf of Bengal, then described as the Tibetan Sea. In the 9th century a war broke out with China which terminated in 821, when bilingual tablets still existing were erected at Lhassa. In 1071 Eastern Tibet was broken up into small states, opening the country to Chinese and Mongol invasion. Kublai Khan, who annexed Tibet to his vast empire, called to his court a Tibetan monk, Phagspa. The latter converted his patron and the Mongols to Buddhism, and the sovereignty of Tibet was conferred on the Dalai-Lamas. In 1720 the Chinese, after many struggles, finally conquered Tibet. Seven years later Batang and other parts of Kham were detached from Tibet, and incorporated with the Chinese province of Sze-chwan. Early in the 18th century Lamas, under the guidance and instruction of Jesuit missionaries, carried out a survey of the Tibetan part of the Chinese empire. From the information supplied D'Anville in 1733 prepared a map of Tibet not yet altogether superseded. In 1840 Ladakh was conquered by the Maharajah of Cashmere, and now is a British dependency. In 1854 there was a struggle between Tibet and Nepal which ended in a treaty by which both countries recognised the suzerainty of China. Eleven years later, in consequence of the refusal of the Tibetan authorities to allow Europeans to enter their country, a system was organised in the interest of science, by which pundits or educated Indians were sent as explorers into Tibet. By this means the old maps have been corrected and much valuable geographical knowledge has been obtained. Prejevalski and other Russian explorers have done for Northern Tibet what the pundits have done for the south. Sikkim, a frontier state through which passes an important route from India into Tibet, became a British dependency in 1850. In 1888 it was attacked by a Tibetan force, and, as the

Chinese government declined and probably was unable to interfere, the invaders were punished by the Anglo-Indian troops. The question was finally settled in March 1890. The Chinese disavowed the war and recalled their amban from Lhassa. Britain retained her possessions. In 1889–90 the journey of M. Bonvalot and Prince Henri d'Orleans across central Asia from Kuldja to Tonquin attracted the attention of French politicians and English merchants. It was said to prove how Russia and France might join hands in Asia. France was to extend westward the frontier of Tonquin to the navigable Mekhong River, and thus secure exclusive possession of the great route into Yunnan and Western Sze-chwan, Chinese provinces belonging geographically rather to Tibet than to China; but the practical efforts of the French to open their route have signally failed.

Tibet Dog. See MASTIFF.

Tibullus, ALBIUS, was probably born at Gabii about 54 B.C. His prænomen and parentage are unknown; his estate was much reduced in the subsequent confiscations by which Octavian and Antony rewarded their legionaries. His father seems to have died early, but his mother and sister survived him. While still a youth he acquired the friendship of the orator, poet, and statesman, M. Valerius Messala, head of a literary coterie only less attractive than that of Mæcenas. As in Queen Anne's day, literature was a direct passport to office under government, and the already marked poetic gifts of Tibullus procured him a place on the staff of Messala commissioned by Augustus, 30 B.C., to crush a revolt in Aquitania. In this campaign the poet displayed capacity enough to win him distinction and decorations, but these could not countervail his repugnance to a soldier's life. Accordingly the close of the war found him dividing his time between the society of Rome and the retirement of Pedum at the base of the Tusculan and Sabine hills. He fell in love with a 'grass widow,' Plania by name, whose husband was on service in Cilicia. Under the sobriquet of Delia she is the heroine of his first book of elegies, but his devotion did not survive the deception she practised on him, finding as he did that he was not her only lover. It was during the earlier period of this attachment that, at Messala's instance, he started with that statesman on a mission to Asia; but, having sickened on the voyage, he got no farther than Corcyra. In his second book of elegies 'Delia' is replaced by 'Nemesis'—this *innamorata* being a fashionable courtesan, with many other admirers besides Tibullus, who bemoans his bondage to her and stigmatises her rapacity, but yet cannot bring himself to drop her.

Tibullus died 19 B.C., immediately after Virgil, universally deplored in Rome, and years afterwards the subject of a magnificent elegy by Ovid. Doubt has been thrown on his identity with the Albius of Horace, but we are loth to part with the picture that poet gives of him, pacing pensively his woodland walks at Pedum, blessed with fortune, with personal beauty, and with all the capacities of refined enjoyment. His character, amiable, generous, loyal to his friends and constant to the mistresses who deceived him, but wanting in strength and energy, is reflected in his poems, which, 'most musical, most melancholy,' by their limpid clearness and their unaffected finish still justify Quintilian in placing him at the head of Roman elegy properly so called. Grace, tenderness, pathos, conveyed in verse smooth without monotony, can, however, only abate, not remove, the impression he leaves of lack of the dramatic force characteristic of Propertius or of the masterly range commanded by Ovid. The third book can hardly, even in part, be considered as his, while the fourth, also by another hand, is yet memorable for the eleven poems on the loves of Sulpicia and Cerinthus—Sulpicia's being unique as specimens of a Roman lady's passionate outburst in verse.

Till Lachmann's edition (1829) not much was done for the text of Tibullus, though his interpretation has advanced but little beyond the older Heyne. The most critical and on the whole useful edition is that of Bahrens (1878). See Ribbeck's *History of Latin Poetry*; the Rev. James Davies, *Catullus, Tibullus, and Propertius* ('Ancient Classics' series, 1876); Teuffel; and Sellar. The best English translation is Dr James Cranstoun's (Edin. 1872).

Tic Douloureux. See NEURALGIA.

Tichborne, a Hampshire property, 2 miles SSW. of Alresford station and 6½ E. by N. of Winchester. It has from before the Conquest been the seat of the Tichbornes, a Catholic family who received a baronetcy in 1626. After the death of the eleventh baronet, Sir Alfred Joseph Tichborne (1839–66), a butcher from Wagga Wagga in Australia, Thomas Castro, otherwise Arthur Orton of Wapping, came forward to personate an elder brother, Roger Charles Tichborne (1829–54), who had been lost at sea off the coast of America. His case collapsed on 6th March 1872, the 103d day of a trial to assert his claims; and the 'Claimant' was on 28th Feb. 1874, the 188th day of this new trial, whose cost was £55,315, sentenced to fourteen years' imprisonment with hard labour for perjury. He died 1st April 1898. See Sir Alex. Cockburn's Charge (2 vols. 1875).

Ticino, a river of Switzerland and the north of Italy, rises on the southern slopes of Mount St Gothard, and flows south through Lake Maggiore, and south-south-east through the north of Italy to its junction with the Po, 4 miles below Pavia. For the last 75 miles of its course, from the point at which it leaves Lake Maggiore, it is navigable. For the battle here in 218 B.C., see HANNIBAL, p. 544.

Ticino (Ger. *Tessin*), the most southern canton of Switzerland, bounded on the W. and S. by Italy, and on the E. by Italy and the canton of Grisons. Area, 1082 sq. m.; pop. (1898) 128,650. Its surface forms a portion of the southern slope of the Alps. In the south the country falls away into flats, and the scenery becomes Italian in character. The principal river is the Ticino (q.v.); and the canton is traversed by the St Gothard railway. In the north cattle-breeding and the preparation of dairy-produce are the chief employments. South of the Alpine regions are elevated forest-clad districts; and farther south olive-yards and vineyards, cornfields and plantations of figs, almonds, oranges, citrons, and pomegranates occur. The canton varies as much in climate as in productions. The northern part of Lake Maggiore and almost the whole of Lake Lugano are included within the canton. The inhabitants for the most part speak Italian, and are Catholics. The largest town is Lugano; since 1881 Bellinzona is the capital.

Tickell, THOMAS, poet, was born in 1686 at Bridekirk in Cumberland, and had his education at Queen's College, Oxford, a fellowship of which he held (without orders by dispensation) from 1710 till 1726. His complimentary verses on *Rosamond* (in Tonson's Sixth Miscellany, 1709) gained him the favour, his own virtues the friendship of Addison, who introduced him both into the world of letters and public life, and on becoming in 1717 Secretary of State made him his under-secretary. He held the office of secretary to the Lords Justices of Ireland from about 1725 till his death, at Bath, 23d April 1740. He was skilful and timeous in occasional poetry, as in *The Prospect of Peace* under Queen Anne, and *The Royal Progress* at the arrival of George I., and he was puffed with all the partiality of affection in the *Spectator*. The most memorable incident in his life was his translation of the first book of the *Iliad* about the same time as the first part of Pope's *Homer*. Addison declared that the rival versions were both good, but that Tickell's was the best that ever was made. Pope believed, or professed to believe it the work of Addison himself, deliberately prepared to eclipse his version, and wrote in reply the famous satire on Atticus. But there need be no doubt that Tickell made his own translation, although Addison corrected it, as he confessed he did. Tickell's 'letter to Avignon,' says Johnson, 'stands high among party poems; it expresses contempt without coarseness, and superiority without insolence.' His longest poem is *Kensington Gardens;* his most popular, the ballad of *Colin and Lucy;* his finest, the exquisite elegy to Addison prefixed to his edition of Addison's Works (4 vols. 1721).

Ticket of Leave. See PRISONS, p. 419.

Ticknor, GEORGE, the historian of Spanish literature, was born in Boston, 1st August 1791, the son of a wealthy New Englander, who was one of the first importers of Merino sheep into the United States. He graduated at Dartmouth College (1807), and was admitted to the bar (1813), but, having practised for a twelvemonth, became convinced that the life of a lawyer would not satisfy his ideas of usefulness or happiness. He accordingly turned his thoughts to plans of study and travel, and, starting for Europe in 1815, for four years resided successively in London, Göttingen, Paris, Geneva, Rome, Venice, Madrid, and Lisbon. Everywhere he mixed in the best society; and his journal is full of the best sort of interviewing, his friends and acquaintances then or afterwards including Joanna Baillie, the Duc de Broglie, Chateaubriand, Miss Edgeworth, Goethe, Guizot, Hallam, Lord Holland, President Jefferson, Jeffrey, Longfellow, Lyell, Macaulay, Metternich, Milman, Prescott, Rogers, Scott, Sydney Smith, Southey, Earl Stanhope, Mme. de Staël, Talleyrand, Thackeray, Daniel Webster, and Wordsworth. Returning to America, he became professor of French and Spanish and of the Belles Lettres in Harvard University. In 1835 he resigned his chair, and went with his family to Europe, where he remained three years, collecting materials for his great *History of Spanish Literature* (3 vols. New York, 1849), an exhaustive and admirable work, which has been translated into Spanish and German. Other works by him were Lives of Lafayette (1824) and Prescott (1864), with fourteen reviews and minor writings. He received nearly a score of literary distinctions; in 1856 revisited Europe; and died in Boston, 26th January 1871, in his eightieth year. See his *Life, Letters, and Journals* (2 vols. 1876).

Ticks (Ixodidæ), a family of mites (Acarina) the members of which attack man, cattle, dogs, birds, reptiles, and some other animals. They live in woods or among thick vegetation, and it is likely that their primary food-supply is derived from vegetable juices; but they are always ready to fasten on some passing animal, and are troublesome pests in tropical and semi-tropical countries. The mite-like body has a tough skin; there are four pairs of clawed legs; the mouth-parts consist (1) of a paired anchoring organ or 'rostrum,' covered with recurved hooks, and equivalent to a 'maxillary lip' or to the pedipalps of other Arachnids, and (2) of a pair of sharp mandibles which play backwards and forwards in two longitudinal channels on the rostrum. Fastening themselves to the skin of an animal, they cut a hole and suck the blood. If allowed to feed till they are satisfied, they withdraw the rostrum and drop off. The sexes differ in appetite, the male being readily satisfied, while the female of some species sucks until, from an almost microscopic size, she becomes the greater part of an inch long. Yet some have been known to survive without food for at least four years. When the satisfied female drops off, she returns to the herbage and begins to lay eggs. Dr A. D. Michael says 'she places the eggs one by one in front of her in a pile or round ball, which gradually becomes almost as large as the mother-Ixodes. It is probably this position of the eggs which gave rise to the idea held by some of the earlier writers that the Ixodes laid their eggs through the mouth-opening; the fact being that the genital opening is very near the mouth, and the position during oviposition such that the mouth is not readily seen.' The typical genus Ixodes includes many species—e.g. the American White-spotted Tick *Ixodes albipictus* and the European *Ixodes ricinus;* the blind genus Argas is well represented by *Argas reflexus*, common on pigeons; *A. persicus*, which produces troublesome punctures on man; and *A. nigra*, sometimes called 'the pique.' It is said that in warm countries the bites sometimes produce fevers, convulsions, delirium, and even death; but Mégnin's experiments (in Europe) lead one to suspect that the danger of the bite has been much exaggerated. As the hasty removal of the tick is certain to leave the rostrum in the wound, the pest should be stimulated with a drop of turpentine or benzole.

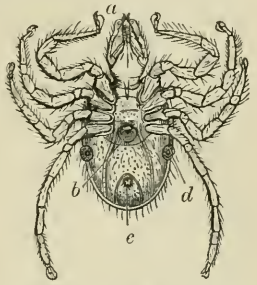

Fig. 1.—*Ixodes ricinus*, fem.: *a*, mouth; *b*, opening of oviduct; *c*, anal valves; *d*, stigma.

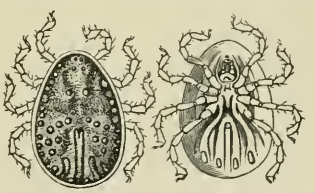

Fig. 2.—Upper and under surfaces of *Argas reflexus*.

The sheep-tick (Melophagus; see SHEEP-LOUSE) is a Dipterous insect, and to the same order belong the species of Nycteribia on bats and of Ornithomyia on birds. The 'death-tick' is a popular name for Pseudoneuropterous insects of the family Psocidæ—e.g. Psocus, Cæcilia, and Clothilla—or for the little Death-watch (q.v.; Anobium).

See ACARINA; also A. Pagenstecher, *Beiträge zur Anatomie der Milben* (Leip. 1860-61); P. Mégnin, *Les Parasites et les Maladies Parasitaires* (Paris, 1880); A. D. Michael, *British Oribatidæ* (1884), and separate memoirs on Ticks.

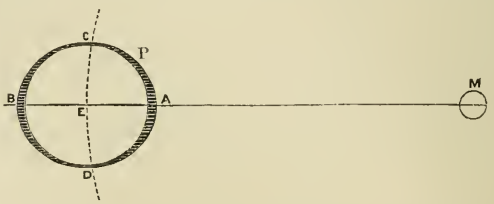
Ticonderoga, a township of New York, 100 miles by rail N. of Albany, on Lake Champlain, and enclosing the outlet of Lake George, whose falls supply water-power for several factories. Black lead and iron also are mined; and here the lake steamers start. Pop. 3400. Here the French built a fort in 1755, which, after repulsing a first attack in 1758, they dismantled and abandoned in 1759, along with Crown Point. The English enlarged and strengthened both fortresses at a cost of £2,000,000; but, being garrisoned with only 50 men after the cession of Canada to Great Britain, it was in 1775 surprised and captured by Ethan Allen. In 1777 it was recaptured by Burgoyne, and in 1780 it was again occupied by the British; at the close of the war it fell into ruins. See Cook's *History of Ticonderoga* (1858).

Tides. To an observer on the seashore no phenomenon is more striking than the rise and fall of the water, the rhythmic ebb and flow which we know as the tides. Roughly speaking, the water reaches its highest level, or high-tide, twice each day, and similarly each day witnesses two low-tides. A little observation soon shows that the time at which high-tide occurs varies from day to day. Thus, if the high-tide occurred at noon yesterday it may not occur till one o'clock to-day. After the lapse of a week low-water will occur about the hour at which high-water was first observed, and high-water at the former time of low-water. When a fortnight has passed the times of high and low tide will be very similar to what they were when first noted, and so on regularly through the year. If these observations of the rise and fall of the tide are combined with lunar observations it will be found that high-water at any place occurs on the average a definite interval after the meridian passage of the moon. The close connection between the age or position of the moon and the time of high-water was recognised long before the true dynamical connection between them was discovered.

Close observation of the height of the tide from day to day will soon disclose the fact that this height varies. For example, on one particular day the tide will rise very high and fall very low; a week later the high-tide will come considerably short of the highest attainable, and the low-tide will not fall as low as the lowest attainable. After the lapse of another week the very high and very low tides will again occur, and so on, timing accurately with the four quarters of the moon. These extreme tidal variations are distinguished as spring-tides and neap-tides. Thus, at London Bridge the average range of the spring-tides is 20 feet 8 inches, that of the neap-tides 17 feet 3 inches. At Leith the corresponding numbers are 16 feet 4 inches and 12 feet 9 inches. Under certain conditions spring-tides rise very high, overflowing low-lying portions of towns and villages.

The general explanation of the phenomenon of the tides was given first by Newton. He supposed the ocean to cover the whole earth, and to assume at each instant a figure of equilibrium under the combined gravitation influence of earth, sun, and moon. The real problem is, however, a kinetic one, and as such was attacked by Laplace. Both the equilibrium and kinetic theories agree in explaining the broad features of the tides. Their results differ in important details, and neither satisfactorily represents the facts. There is no doubt, however, that the failure of the kinetic theory in this respect arises from our inability to take proper account of the configuration of land and sea, of the varying depths of ocean, and of the effects of fluid friction. It is impossible without mathematics to give any account of the kinetic theory. It must suffice to say that the problem consists in finding the forced oscillations of the ocean under the periodic tidal action of the sun and moon. Meanwhile we shall consider the faulty equilibrium theory, and see how far it explains the principal tidal phenomena described above.

Let M be the centre of the moon, and E that of the earth. Imagine a sphere, CD, described with M as centre and passing through E. Then it is evident that all particles on the nearer side to the moon will be more strongly attracted than those on the farther side of this spherical surface. Thus, if A is the nearest point on the earth to the moon and B the farthest distant point, there will be a greater



pull towards M at A than at E, and at E than at B. Again, at any point, P, which lies off the line ME, there will be a pull inwards towards ME. And thus, if fluid covers the whole surface APB, there will be a heaping up of the waters (relatively to E) at A and B and a sinking of them at C and D. The approximately spherical figure of the water-surface will be forced to take a spheroidal form, with greater axis pointing towards the moon. This form will follow the moon in its apparent daily course, and the result will be that twice every lunar day (24 h. 54 m.) high-tides and low-tides will be experienced at every point on the surface for which the moon rises above the horizon. This so far agrees with observation; but it is not found that in general the high-tide occurs simultaneously with the passage of the moon across the meridian. When it does, it is because the high-tide has, through the configuration of land and sea, lagged behind the moon by a whole half-day at least. At islands in the open sea or at ports looking eastwards across a broad ocean the time of high-tide is generally a few hours later than the meridian passage of the moon.

Now the sun as well as the moon will produce tides. The tide-generating power of a given body may be taken as proportional to the difference of the attractions exerted on the nearest and the farthest distant points of the affected globe. For example, if m is the moon's mass, its tide-generating power will be proportional to $m/MA^2 - m/MB^2$ (see GRAVITATION). But

$$\frac{1}{MA^2} - \frac{1}{MB^2} = \frac{MB^2 - MA^2}{MB^2 MA^2} = \frac{(MB + MA)(MB - MA)}{MB^2 MA^2}$$
$$= \frac{2ME \cdot AB}{ME^4} \text{ approximately } = \frac{2AB}{ME^3}.$$

Hence the tide-generating power will be proportional to the mass and to the inverse cube of the distance of the tide-producing body. Now the sun's mass is nearly 2,700,000 times the moon's mass, and the sun's distance is about 390 times the moon's distance. Consequently the sun's tide-generating power should be to the moon's in the ratio of 2,700,000 to 390^3—i.e. roughly, 5 to 11. At new and full moon the tides due to the sun and moon will fall crest to crest and trough to trough, and the total tide may be represented by 16 (5 + 11). On the other hand, at times of half-moon the crest of the lunar tide will coincide in position with the trough of the solar tide, and the resultant tide may be represented by 6 (11 – 5). Here we have at once the explanation of the spring and neap tides. In general the spring and neap tides do not

differ by nearly so much as these numbers indicate. The spring-tide is seldom a half greater than the neap-tide. By the theory, spring-tides should occur at new moon and full moon, and neap-tides when the moon is in quadrature. In fact they occur about one and a half days later than the corresponding astronomical combinations.

As the moon passes through its first quarter the solar tide having a shorter period gradually shoots ahead of the lunar tide. For any position between new and half moon the crest of the resultant tidal wave will therefore pass a little sooner than it would if the moon alone were acting. Similarly for any position between half moon and full moon —that is, during the second quarter—the crest of the resultant tide will lag behind the position it would occupy were the moon the sole agent. In the former case the tide is said to *prime* and in the latter to *lag*. The same phenomena occur in the third and fourth quarters. This priming and lagging of the tide are very evident phenomena. Their effect may be readily observed by inspection of any table of tides, in which the intervals between successive high-tides will be found to vary considerably. As the time of maximum priming is being approached the successive tides follow each other at shorter intervals than they do when the time of maximum lagging is being approached.

When the moon is in the plane of the equator the two daily tides at each point on the water-surface (supposed uniform) will be approximately equal. But if the moon is, say, north of the equator, then for any point on the north side of the equator the tide corresponding to the meridian moon will be a little higher than the other, since the tidal spheroid has its long axis inclined to the equator; and for any point on the south side of the equator this tide will be the lower of the two. When, on the other hand, the moon is south of the equator it is for southern latitudes that the higher tide is the one corresponding to the moon's meridian passage. It is usual to represent this phenomenon as due to a diurnal tide superposed upon the semi-diurnal tide. The lunar diurnal tide does not exist when the moon's declination is zero; and it vanishes at the equator and the poles. There is also a solar diurnal tide depending on the sun's declination. Then there are the tides of long period—viz. the *fortnightly* tide depending on the elements of the moon's orbit round the earth, and the *semi-annual* tide depending on the elements of the earth's orbit round the sun.

Tidal phenomena, as observed at different localities, present very complicated features, which it would be hopeless to attempt to describe. Two tidal waves flowing round the opposite extremities of continents or islands may meet again, and give rise to very peculiar effects. The four daily tides observed at Colombo are referred to this cause; and a similar explanation probably holds for the very extraordinary case of Papiete, one of the Society Islands, where the high-tide occurs invariably between noon and 2 P.M. In the Pacific islands generally the tide is small, frequently not exceeding 2 feet. In bays again high-tides are generally experienced. The phenomenon in its simplest form is shown in the Bay of Bengal, in which the tide gets higher as it advances along the narrowing channel. The exceptionally high tides in the Bay of Fundy are due to the same cause, combined with the fact that two tidal waves meet off its mouth. The *Bore* (q.v.) or wave which runs up estuaries is another illustration of the same phenomenon (see also CHEPSTOW). In the Mediterranean Sea we have the case of a not very extensive sheet of water communicating with the outer ocean by a narrow strait. The result is that in its central parts (at Malta for example) there is no appreciable tide. At the head of long bays, such as in the Adriatic, the tide is, however, quite evident, though small. In straits and estuaries the ebb and flow of the tide is frequently accompanied by strong currents. These tidal currents have been utilised as a source of power at various places (Argostoli, Burntisland, Woodbridge, &c.). Their generally intermittent character limits their operation somewhat. It has also been suggested to use the rise and fall of the tides for driving dynamo-electric machines, so as to transform tidal energy into electric energy; but no practical scheme has as yet been devised. Obviously experiments of this kind could be best carried out where either high-tides or strong tidal currents are experienced.

It is customary to apply the term tidal wave to any large wave which, even though it be but for a short time, causes an exceptional rise of sea-level along a shore. Such waves very frequently accompany Earthquakes (q.v.). They are in no true sense *tidal*.

Tidal machines are of two classes. Those of the one type are intended to record at any given place the march of the tide. This is effected by an arrangement of floats; and the record is made by a pencil bearing on a revolving cylinder. Such machines are called tide gauges. The other kind, first imagined by Lord Kelvin, is for predicting tides at any place whose various tidal constituents have been determined by harmonic analysis from the record of the tide gauge. Each harmonic constituent is produced by motion of a pulley; and a single cord passing round all the pulleys, which by their motions give the different harmonic constituents, compounds those motions, the resultant being recorded on a revolving cylinder by a pencil fixed to the free end of the cord.

Corresponding to the tides as they exist in the fluid portion of the earth there are tidal stresses in the solid crust. These are resisted by the rigidity of the material; but it is possible that they may be a factor in the production of Earthquakes (q.v.). G. H. Darwin has considered the question as to whether there is any yielding of the crust under the influence of the long period tidal stresses. He finds evidence of a slight yielding, showing that the earth has an effective rigidity about equal to that of steel.

In the evolution of worlds tidal action has had a very important influence. It has long been recognised that in the case of the earth the tidal wave must act as a kind of friction-brake, gradually retarding the rate of rotation. But any such change in the rate of rotation of the primary body must be accompanied by changes in the distance and time of revolution of the moon. Calculating backwards in time G. H. Darwin has found that originally the moon must have been much nearer the earth. Previous to the time of its existence as a distinct satellite it was part and parcel of the earth; and its origin as a satellite is believed to have been due to the tidal action of the sun acting upon a fluid or semi-fluid body whose period of rotation was nearly equal to its natural period of oscillation. Thus the properly timed tidal impulses acted so as to produce large tidal distortions, which finally resulted in the separation of the body into two parts. The tidal action of the earth upon the moon has long ago compelled the latter to rotate upon its axis in exactly the same time as it revolves in its orbit. For there can be little doubt that before the moon had cooled down to its present unchangeable condition very large tides must have been generated in it, and these would act as friction-brakes so long as the period of the moon's axial rotation was shorter than its time of orbital revolution. There is evidence that Jupiter's satellites have the same peculiarity; and it is now believed

that Venus and Mercury have their day equal to their year. The greater proximity of the sun to the two inferior planets would produce correspondingly greater tides with correspondingly quicker reduction of the axial to the orbital period.

Tideswell, a small town of Derbyshire, 6½ miles E. of Buxton, with an old cruciform church, and some silk manufactures. Pop. 1985.

Tieck, JOHANN LUDWIG, one of the most prominent champions of Romanticism (q.v.) in Germany, and the friend of Novalis and the Schlegels, was born in Berlin on 31st May 1773. Most of his life was spent in that city, in Dresden, and near Frankfort-on-the-Oder, his life's calling being that of a man of letters; and in Berlin he ended his days, on 28th April 1853. After two or three immature romances, he struck out a new line in clever dramatised versions of the old fairy-tales, such as Fair Eckbert, Puss in Boots, The Faithful Eckhart, Blue Beard, and others, which he made the vehicle for some polished satire on contemporary literature. This is Tieck's peculiar groove. He followed up this first success—*Volksmärchen von Peter Lebrecht* (1797)—by publishing the tragedy *Leben und Tod der Heiligen Genoveva* (1800), the comedy *Kaiser Octavianus* (1804), and *Phantasus* (1812-17), a collection of the same class of traditional lore in story and drama. These books became great favourites in Germany, owing to the simple and agreeable style of the narrative, and the dreamy fancy and delicate irony that pervaded them. Another great favourite was a romance in glorification of art, entitled *Franz Sternbald's Wanderungen* (1798). In his later years Tieck wrote several works of a more modern cast, of which *Die Gemälde*, *Die Reisenden*, *Die Verlobung*, *Hexensabbath* are amongst the most highly esteemed. Besides superintending the completion of A. W. Schlegel's translation of Shakespeare's plays—it was long erroneously believed that he had translated them himself—he edited the doubtful plays and wrote a series of essays (*Shakespeare's Vorschule*, 1823-29). *Don Quixote* he did translate with his own hand (1799-1804). He holds an honourable place in the ranks of Germany's dramatic and literary critics, in virtue of his *Dramaturgische Blätter* (2d ed. 1852) and *Kritische Schriften* (1848). Tieck's *Schriften* were published in 28 vols. in 1828-54, and his *Novellen* in 12 vols. in 1852-54. Some of his fairy-tales and novels were translated into English by Carlyle and Thirlwall. See biographies by Köpke (1855) and Friesen (1871); and Carlyle's *Essays*, vol. i.

Tiel, a Dutch town in Guelderland, on the Waal, 60 miles E. by S. of Rotterdam. Pop. 9431.

Tiele, CORNELIS PETRUS, Dutch theologian, was born at Leyden, 16th December 1830, studied at the university there and at the Remonstrants' seminary at Amsterdam, and became Remonstrant pastor at Rotterdam (1856), professor in the seminary translated to Leyden (1873), and professor of the History of Religions in the university of Leyden in 1877. From its foundation in 1867 he collaborated with Kuenen, Loman, and Rauwenhoff in editing the well-known *Theologisch Tijdschrift*; and he has published a long series of important theological works. Of his writings there have been translated into English the *Comparative History of the Egyptian and Mesopotamian Religions* (1869-72; Fr. trans. 1882; Eng. by James Ballingal, part i., *The Egyptian Religion*, 1882); *Outlines of the History of Religion to the Spread of the Universal Religions* (1876; Eng. trans. by J. E. Carpenter, 1878). Other works discuss the Gospel of John as a source of the Life of Jesus (1855), the Religion of Zarathustra (1864), *Babylonisch-assyrische Geschichte* (1886-87), &c.

Tien-tsin, a large city and river-port of China, in the province of Chih-li, on the right bank of the Pei-ho, 34 miles from the mouth of the river. It is the port of the city of Peking, from which it is distant 80 miles SE. The river is generally frozen over from about the 15th December to the 15th March, and the business at other times carried on by means of boats and junks is taken up by sledges, which swarm on the river. By the treaty of Tien-tsin, signed here in 1858, the port was declared open; and a British consulate was established in January 1861, while part of the allied troops were still here (see CHINA, Vol. III. pp. 192, 193). In 1881 Tien-tsin was connected by telegraph with Shanghai, and in 1897 with Peking by rail; and there is a railway from Tien-tsin to the mouth of the Pei-ho, which will ultimately be extended to Shanghai. The imports have an annual value of £500,000, the exports of about £1,000,000. Pop. estimated in 1900 at 1,000,000. In 1900 Tien-tsin, taken by the allies, became the base of operations against Boxers and Chinese.

Tiepolo, GIOVANNI BATTISTA, the last of the great Venetian school, was born at Venice 5th March 1692, and modelled himself on Paul Veronese. His first works were in the adornment of churches and palaces in and about Venice; in 1750-53 he executed a great series of frescoes in the archiepiscopal palace at Würzburg, and in 1760 was engaged on the palace of Madrid. At Madrid he died, 27th March 1769. He was a most productive painter, rich in colour (especially in his easel pictures), and clear (though incorrect) in drawing. His chief works were the Old Testament histories—the palace at Udine and the frescoes at Madrid. His two sons were also painters, and like their father etchers also. See Molmenti, *Il Carpaccio e il Tiepolo* (Turin, 1885).

Tierney, GEORGE (1761-1830), Whig politician, was one of Pitt's most persistent opponents, and fought a bloodless duel with him (1798). He held office in the ministries of Addington, Grenville, Canning, and Goderich. He was a clever debater, notorious for his powers of sarcasm.

Tierra del Fuego consists of a group of several large and numerous small islands, lying off the south extremity of South America, in 54° S. lat., 70° W. long., and separated from the continent by the Strait of Magellan. Its farthest south point is formed by Cape Horn. The principal island, Tierra del Fuego, sometimes known as King Charles South Land, is divided between Chili and the Argentine Republic, to the latter of which Staten Island also belongs. All the other islands and islets are included in Chili. The shores of the archipelago are generally much broken by and indented with bays and arms of the sea, with mountains rising abruptly from the water. These fjords, as a rule, contain deep water at their shoreward extremities, with bars, or, more properly, banks at the sea entrances; in this feature, as well as in their scenery, resembling many of the salt-water lochs on the west coast of Scotland. The whole group is mountainous, the high hills of the mainland (Tierra del Fuego) attaining a height of 7000 feet, the snow-line being at an altitude of 4000 feet above sea-level. There are some dreary plains and a few fertile river-valleys, with areas of marshy ground between Useless and St Sebastian Bays. None of the rivers are important, unless it be the Juarez Celman, which is believed to be navigable for a considerable distance above its mouth. Towards the north the plains produce good pasturage, and attempts at sheep-farming have been made in the district, the Jesuit missionaries on Dawson Island having a farm with nearly 20,000 sheep and over 6000 cattle. Forests of

beech, winter's bark, magnolia, and cypress cover large areas, with dense growths of such bushes as Berberidæ, Escallonia, *Ribes magellanica*, Embothrium, *Myrtus mummularia*, and Saliceminæ on the hill slopes. Lichens grow abundantly at greater heights, and cover much of the low grounds, where, apparently, nothing else can flourish. The more common and old-fashioned English garden flowers come to perfection in the settlers' enclosures in the extreme north. Few island groups situated so close to continental land exhibit a poorer fauna than is here presented, the guanaco, tucu-tucu (a small rodent), dog, fox, and rat being the only quadrupeds, with the exception of the lately introduced farm stock. The dog is semi-domesticated, and is kept by the natives in immense numbers. Birds, however, are abundant and various, including *Vanellus cayanus*, *Surnia funerea*, owls, gulls, falcons, and a great variety of sea-birds. Seals and sea-lions, once almost innumerable along the shores, have grown scarce and wild, especially in the northern portion.

The land of Tierra del Fuego is rapidly rising, and the coast-line has advanced 3 kilomètres since the date of the surveys of Captains King (1826–28) and Fitzroy (1831–36). The rocks are principally volcanic, but sedimentary strata are not uncommon on the principal island, and probably on some others. Granite, syenite, porphyry, quartz, serpentine, trachite, diorite, and sandstone comprise the principal rocks. Some coal, of a poor description, and a little gold have been found. The situation of the islands exposes them to a series of conditions which render their climate the most tempestuous in the world. The prevailing winds are from the west, beginning to blow with the rise of the sun, and increasing in violence until dusk, when a calm may generally be looked for with confidence. During the short summer the winds blow from the north. Settled weather never lasts for more than a fortnight at a time. December, January, and February are the warmest months. March is exceedingly boisterous always, and during its course occur the most destructive gales.

The people are savages of a low type, divided into three tribes, the Onas (or Aonas), the Yaghans, and the Alakalufs, the Yaghans being now supposed to be the aborigines. The Onas are tall, the others short and stunted in stature. The charge of cannibalism once brought against them appears to be unfounded. They number about 8000 souls.

Tiers État. See STATES-GENERAL.

Tietjens. See TITIENS.

Tiffin, capital of Seneca county, Ohio, on the Sandusky River, 43 miles by rail SSE. of Toledo. It is the seat of Heidelberg College (Reformed Church; 1851), and manufactures farming implements, churns, stoves, woollens, &c. Pop. 10,801.

Tiflís, the chief city of the government of the same name and the capital of Russian Caucasia, on the banks of the Kûr, 165 miles as the crow flies ESE. of the Black Sea. Since 1883 it has been connected by rail with Batoum on the Euxine and Baku on the Caspian, and is the chief centre of trade between Russia and Persia. The old city, which consisted of three distinct parts, and which traces its history as the capital of the Georgian princes back to the 5th century, has been greatly metamorphosed since the Russian occupation in 1795 and annexation in 1802. It is now divided into quarters assigned to the various nationalities, and possesses handsome public buildings, churches, schools, libraries, and observatories. In the middle ages the metal-workers of Tiflís were famous for their skill in engraving and inlaying, and their influence made itself felt in the brass-work of Venice; and to the present day the silversmiths and gunsmiths of the city maintain their character for excellence. Otherwise its manufactures (carpets and other textiles) are unimportant. In its neighbourhood are naphtha and thermal springs. The population in 1897 numbered 160,645, of whom about a third were Armenians.—For the *government*, see RUSSIA, and CAUCASUS; and see also GEORGIA.

Tiger (*Felis tigris*), a well-known feline Carnivore, belonging to the same genus as lion and leopard, lynx and cat, puma and jaguar. It seems most nearly related to the lion, from which it hardly differs except in superficial characters, such as the colour-striping and the absence of a mane, and in trivial skeletal features, especially of teeth and skull. In distribution the tiger is exclusively

Tiger (*Felis tigris*).
(From a Photograph by Gambier Bolton, F.Z.S.)

Asiatic, and has been found 'in almost all suitable localities south of a line drawn from the river Euphrates, passing along the southern shores of the Caspian and Sea of Aral by Lake Baikal to the Sea of Okhotsk. Its most northern range is the territory of the Amur, its most southern the islands of Sumatra, Java, and Bali. Westwards it reaches to Turkish Georgia, and eastwards to the island of Saghalien. It is absent, however, from the great elevated plateau of central Asia, nor does it inhabit Ceylon, Borneo, or the other islands of the Indo-Malayan Archipelago, except those above mentioned.' The tiger may exceed the lion in length. Adult males measure 5½ to 6½ feet from the nose to the root of the tail, and the tail measures about 3 feet. The females are rather smaller. Blandford gives authentic instances of

tigers over 10 feet long (with the tail), and weighing nearly 500 lb. The predominant colour is bright rufous fawn or tawny yellow, and is barred by dark or black cross stripes; the under parts are whitish. In details the dark markings vary considerably. The favourite haunts of the tiger are grassy plains and jungle swamps, where its colour often harmonises most deceptively with that of the surroundings. The animal takes readily to the water and swims well; it can also, if circumstances press it, climb trees. Like other Felidæ, the tiger is a solitary hunter and stalks its prey stealthily till within the fit distance for making a final spring. It feeds on cattle, deer, wild hogs, pea-fowl, &c., and some old 'man-eaters' haunt the neighbourhood of villages on the outlook for human prey. 'The man-eater,' Mr G. P. Sanderson says, 'is often an old tiger (more frequently a tigress), or an animal that, through having been wounded or otherwise hurt, has been unable to procure its usual food. It is as cowardly as it is cunning, fleeing before an armed man, between whom and a possible victim it discriminates with wonderful sagacity.' Young tigers are said to glut their taste for blood far beyond the limits of hunger, and the same is true of the mother while the young are still her companions. Sir Joseph Fayrer reports that a tiger will in ordinary circumstances destroy one or two cows or buffaloes a week, refraining from fresh attacks until it has consumed the results of one night's work. In attacking a large animal, such as a bullock, the tiger seizes the nape of the neck with its teeth, holds the victim firm with its sharp claws, and with a powerful wrench dislocates the vertebræ. From two to six cubs are born at once, and these the tigress guards, feeds, and trains with all maternal care. They remain with her until nearly full grown, or about the second year. It is said that the male tigers are eager to destroy young male cubs; and apart from this occasional cannibalism is recorded. In some parts of the East tigers are numerous enough to endanger human life very seriously; and tiger-hunting is in these conditions 'a most noble sport.' In 1882 the population of a village in the south-west of the Bantam province was removed and transferred to an island off the coast in consequence of the trouble caused to the people by tigers. Baker regards the tiger as a more formidable and ferocious beast than the lion. In spite of the government rewards, lack of enterprise and a superfluity of superstition still afford the tigers a wide range in India. In the three years ending 1889, for instance, 546 people were killed by tigers in Central India alone, besides 6882 head of 'cattle' ('including asses and pigs').

See Felidæ; also W. H. Flower and R. Lydekker, *Study of Mammals* (1891); Sir J. Fayrer, *Royal Tiger of Bengal* (1875); W. T. Blanford, *Fauna of British India* (1888); St George Mivart, *The Cat* (1881); Elliot, *Monograph of the Felidæ* (1878–83); Sir Samuel Baker, *Wild Beasts and their Ways* (1890). For so-called tiger-cats, see Margay, Ocelot, and Serval. The jaguar is the *tigre* of South America. Tiger-wolf is a name given to the spotted hyæna and to the Thylacine. 'Tiger-moth' is any of the Arctiidæ (whose larvæ are 'woolly bears'); and 'tiger-beetle' is a Cicindella (q.v.).

Tiger-flower (*Tigridia*), a genus of plants of the natural order Iridaceæ. There are about seven known species, natives of Mexico, Peru, and Chili, all bulbous plants, generally treated as half-hardy or greenhouse plants. The flowers are few, enclosed in a spathe. The perianth has a short tube with a six-parted spreading limb; there are three stamens united in a cylinder, a three-celled ovary with a filiform style which has three filiform bifid stigmas. The best known of the species in British gardens is *T. pavonia*, which has been cultivated for nearly 100 years for the beauty of its rather evanescent flowers. The flowers are orange, spotted tiger-like, hence the name.

Tiger-lily. See Lily.

Tight-lacing. It has long been recognised that undue compression by the clothes, and particularly by stays, of the waist and lower part of the chest causes disturbance of the relations of the internal organs, and impairs their functions; producing, e.g., distortion of the liver and stomach, breathlessness, impaired digestion, and diminished capacity for exertion. More recently it has been maintained that the tendency to various more definite diseases is caused or much aggravated by this condition. Among these may be mentioned certain displacements of the womb, and other diseases peculiar to women; movable kidney, gall-stones, anæmia, and ulcer of the stomach, which are all more common in the female sex than the male. While it cannot be said that the causal relation is definitely established in any of these cases, there are facts in regard to each which render it at least possible that such a relation may exist.

In a case where an injurious effect of any kind is present or is suspected, it is not sufficient merely to discontinue the use of stays, for that would only bring the constricting bands by which the lower garments are usually supported to bear still more directly on the waist. Some arrangement must be made by which the weight of these garments may be borne by the shoulders and bust, either by having each one made with an upper part fitting the chest and shoulders, or by having them attached by buttons or tapes to a stout but not tightly-fitting bodice. It is much to be desired that more attention were paid to the natural conformation of the body, and less to the unreasonable demands of fashion, in the matter of dress.

Tigranes. See Armenia, Mithridates.

Tigré, the northern division of Abyssinia (q.v.).

Tigris (Heb. *Hiddekel; Diklat* of the cuneiform inscriptions; *Tigrâ* in Old Persian, 'swift as an arrow,' whence Gr. *Tigris;* Arab. *Dijleh*), a large river of Asiatic Turkey, rises south of Lake Goljik, in the mountains of Kurdistan, within a few miles of the eastern bend of the Euphrates (q.v.), flows south-east to Diarbekir, after which it makes a sharp turn and flows due east for 100 miles to Til. Here it receives from the north a considerable affluent, the Bitlis (united with the Bohtan Su), and once more altering its course runs in a south-easterly direction, mainly through desert wastes and unpeopled pastures, until it falls into the Persian Gulf, after a course estimated at 1150 miles. Its chief tributaries, beside the Bitlis, are the Great and Little Zab, and the Dyala, all from the left. At Kurna it joins the Euphrates, 90 miles above the mouth of that river in the Persian Gulf, and henceforth the united rivers bear the name of Shat-el-Arab (see Euphrates). In the upper part of its course the Tigris is a very swift stream, and it brings down great quantities of mud. The principal places on its banks are Diarbekir, Mosul, and Bagdad, with the ruins of Nineveh, Seleucia, and Ctesiphon. The river is navigable for small steamers to Bagdad, and for river-boats to near Mosul.—For the Bocca Tigris, see Boca Tigre, and Canton.

Tilburg, a town of Holland, 14 miles ESE. of Breda, is an important railway junction, and has 300 manufactories of calico, cloth, leather, &c. Pop. (1871) 22,256; (1891) 34,492.

Tilbury Fort, in Essex, is situated on the north bank of the Thames, opposite Gravesend, and 22 miles E. of London. Originally erected in

the time of Henry VIII. as a block-house, it was converted (1667) into a regular fortification after the bold expedition of De Ruyter into the Thames and Medway, and has been greatly strengthened since 1861. Here on 8th August 1588, more than a week after the dispersal of the Spanish Armada, Elizabeth reviewed her troops. The East and West India Dock Company constructed extensive docks at Tilbury in 1882-86 (see Vol. IV. p. 30).

Tilden, Samuel Jones, American statesman, was born the son of a farmer at New Lebanon, New York, 9th February 1814, studied at the University of New York, and was admitted to the bar in that city, and secured a large and important railway practice. By 1868 he had become the leader of the Democrats in the state, and he strengthened his position by the energy and determination with which he attacked and destroyed Tweed and his fellows (see Tammany). In 1874 he was elected governor of New York; in 1876 he was the Democratic candidate for the presidency (for the disputed election, see Hayes), and not only won general admiration, but possibly saved the excited country from something worse than fierce wrangling, by his temperate utterances and unselfish attitude. Twice afterwards his party would have nominated him had he been willing. He died 4th August 1886, leaving great part of his fortune of $6,000,000 to found and endow a free library in New York City. There is a Life by T. P. Cook (1876), and an edition of his writings and speeches by John Bigelow (2 vols. 1885).

Tiles, plates of baked clay, of various shapes and patterns, according to their use, some being for roofs, some for facing walls, and others for pavements. Marble and stone slabs used for covering roofs are also sometimes called tiles. Drain-tiles have been described under the head of Pipes. The small cubical pieces of burnt clay, stone, glass, or other material used for mosaic pavements are called tesseræ (see Mosaic).

Encaustic Tiles are ornamental tiles made of earthenware, and now extensively used for paving churches, halls, conservatories, &c. Strictly speaking, the name applies only to tiles with a pattern produced by layers of different coloured clays. By R. Prosser's process (patented in 1840) tiles of one colour are made of dried slip—i.e. the powder of carefully mixed and prepared clay. These are made by placing the coloured clay powder in strong steel moulds, and consolidating it in a semi-dry state, by means of a plunger fitting accurately into a mould worked by a screw-press. It is then removed, heated in a hot chamber, fired, and glazed if required.

Encaustic tiles are made by two quite different processes. By the older of these, which is a revival of that used in mediæval times, the clay is worked in a plastic state first into square blocks. These are cut into square slices or slabs by passing a wire through them; upon a slab so cut is put a facing of fine clay of the colour of the ground of the pattern—another layer of fine clay being added to the bottom to prevent warping. By means of metal containing-frames, fitting into each other, a plaster of Paris mould or reverse is pressed with a screw-press into the face of the soft tile, and thus indents the pattern. Clay of the requisite colour to form the pattern is now poured in a semi-fluid state into this depression, the tile being then set aside until dry enough to have its surface scraped. By this means the superfluous clay is removed, and the pattern is brought out clear and well defined, the two or more colours of clay forming one smooth flat surface. The tile is then dried and fired.

The other process of making encaustic tiles is by the use of perforated brass plates and a screw-press, clay powder or 'dust,' prepared in the same way as in Prosser's method, being used. It was patented by Boulton and Worthington in 1863, and is extensively used. By this process the device on the tile is first made by pressing clay dust into the perforations of a brass plate laid on a metal block; or if it is of more than one tint, then dust of two or more colours, with as many brass plates, is used to build up the pattern. The plates being removed, the clay powder which is to form the body of the tile is then filled into a mould round the device, and the whole consolidated by pressure.

Encaustic tiles were used for paving churches in the north of Europe from the 12th to the 16th century; but in Spain and Italy the mediæval and later paving-tiles had their patterns produced in thick enamel glaze on the surface, and were not so durable as when made with two or more layers of different coloured clays.

Wall Tiles of a highly decorative character were made at least as early as the 12th century in Persia, and it is very probable for a long time before that. The manufacture was continued into the 17th century before the artistic merit of the designs declined. Many, if not most, of the earlier of these mural tiles have designs of a very effective but simple kind painted in enamel glazes of a coppery or dull golden colour, with sometimes a little blue or other tint added, the whole surface having a quiet but pleasing lustre. Others, perhaps a little later in date, while retaining some of this flat coppery painting, have in addition bold ornament and inscriptions in relief, which are further picked out from the light ground by deep blue or greenish-blue colour. The tiles of this class were of larger size, and were used for dadoes, large panels, and cornices or friezes, or a combination of both. They have generally a brilliant lustre, which varies their effect when viewed at different angles. Very beautiful wall tiles without lustre and with ornament somewhat different from the above, but still retaining a Persian character, were made at Damascus, Rhodes, and perhaps other places in the 16th century. The mosques of Damascus and other towns in Asiatic Turkey, as well as those of Cairo, and buildings in Moorish Spain, contain splendid examples of wall-tile decoration; while the mosques in some of the older towns in Persia are similarly decorated with tiles which are distinctly Persian. Coloured tiles are also employed for covering the domes and towers of some churches in Spanish America (see, e.g., Montevideo).

For coloured representations of these mural tiles, see P. D'Avennes, *L'Art Arabe* (1877), and H. Wallis, *Persian Ceramic Art* (Godman collection, 1891); also Persia, p. 70; and C. T. Davies, *The Manufacture of Bricks, Tiles, Terra Cotta, &c.* (new ed. 1889).

Tiliaceæ, a natural order of exogenous trees and shrubs, or rarely herbaceous plants, mostly natives of the tropics, though a few are found in the temperate parts of the northern hemisphere. They have simple, alternate leaves, with stipules and axillary flowers. As the characters somewhat correspond with those of Malvaceæ, so do the properties of the order, which are generally mucilaginous and wholesome, the bark fibrous. There are about 46 genera and 330 species. Some yield a light and useful timber, as the Lime (q.v.) or Linden tree. The *bast* of the lime-tree is valuable from its fibrous character; various Indian and American species are useful on this account, but the most important fibrous plants of the order are the species of Corchorus, which yield Jute (q.v.).

Till. See Boulder-clay, Pleistocene.

Tillandsia. See Bromeliaceæ.

Tillemont, Louis Sébastien le Nain de, ecclesiastical historian, was born in Paris, 30th November 1637, had his education from the Port-Royalists, and early devoted himself to historical studies. He entered the priesthood in 1676, and after the dispersion of the Solitaires in 1679 spent most of the remainder of his life on his estate at Tillemont near Paris. Here he died, 10th January 1698. His chief works are the laborious and solid *Mémoires pour servir à l'Histoire Ecclésiastique des Six Premiers Siècles* (16 vols. 1693–1712) and the *Histoire des Empereurs qui ont régné durant le Six Premiers Siècles de l'Église* (6 vols. 1691–1738).

Tillicoultry, a manufacturing town of Clackmannanshire, at the base of the Ochils and near the right bank of the Devon, 10 miles ENE. of Stirling and 4 NNE. of Alloa. Woollens have been manufactured here since the 16th century, and since 1824 also shawls and tartans, tweeds and silk fabrics. Pop. (1851) 3217; (1891) 3939.

Tillodonts. See Eocene System.

Tillotson, John Robert, Archbishop of Canterbury, was born the son of a Puritan clothier, at Sowerby in Yorkshire, in October 1630. He studied at Clare Hall, Cambridge, graduated B.A. in 1650, and became a fellow the year after. The writings of Chillingworth influenced him early, not less the conversation of Cudworth, and others of his school. In 1656 he became tutor in the house of Edmund Prideaux, Attorney-general under the Protector. He is said to have received his orders from Sydserf, Bishop of Galloway, and at any rate he was a preacher by 1661, when we find him ranged among the Presbyterians at the Savoy Conference. He submitted at once to the Act of Uniformity (1662), in December of the same year declined Calamy's church of St Mary Aldermanbury, London; but in 1663 became rector of Keddington in Suffolk, the year after preacher at Lincoln's Inn, where his mild, evangelical, but *un*doctrinal morality was at first little relished—'Since Mr Tillotson came,' said the Benchers, 'Jesus Christ has not been preached among us.' That same year he married a niece of Oliver Cromwell, and became lecturer at St Lawrence's Church in the Jewry. In 1670 he became a prebendary, in 1672 dean, of Canterbury. Along with Burnet he attended Lord Russell on the scaffold (1683). In 1689 he was appointed Clerk of the Closet to King William and dean of St Paul's, and in April 1691 was raised to the see of Canterbury, vacant by the deposition of the Nonjuror Sancroft. He accepted this elevation with the greatest reluctance, nor could all the insults of the Nonjurors to the end of his life extort either complaint or retaliation from the meek and tolerant primate. He died of palsy, 22d November 1694. His *Posthumous Sermons*, edited by his chaplain, Dr Ralph Barker, filled 14 volumes (1694), and for them the booksellers gave the unwonted sum of 2500 guineas. A complete edition of his whole works, including 254 sermons, appeared in 3 vols. folio, 1707–12; with a good Life by Dr Thomas Birch, 1752; and an annotated selection of his sermons by G. W. Weldon (1886). The judgment of Tillotson's preaching by his contemporaries is thus summed up by Burnet: 'He was not only the best preacher of the age, but seemed to have brought preaching to perfection; his sermons were so well heard and liked, and so much read, that all the nation proposed him as a pattern, and studied to copy after him.' Dryden used to say that what talent he had for English prose was due to his familiarity with Tillotson, and Locke recommends him as a model of perspicuity and propriety in language.

Tilly, Johann Tserklaes, Count of, a famous general of the Thirty Years' War, was born in 1559, at the castle of Tilly in Brabant. Educated by the Jesuits, he learned the art of war in the Spanish service under Parma, next fought in Hungary against the Turks, and was appointed in 1610 by Duke Maximilian of Bavaria to reorganise his army. He was given the command of the Catholic army at the outbreak of the Thirty Years' War, and in conjunction with Duke Maximilian gained (8th November 1620) the battle of Prague, which dissipated the ambitious dreams of the Elector-Palatine. During the course of this war he separated, by able strategy, the armies of Mansfeld and of the Margrave of Baden, beat the latter at Wimpfen (6th May 1622), expelled Christian of Brunswick from the Palatinate, defeating him at Höchst (20th June 1622) and at the desperate struggle at Stadtlohn (6th August 1623). Created a count of the empire, he next defeated the king of Denmark at Lutter (27th August 1626), and in conjunction with Wallenstein compelled him to sign the shameful treaty of Lübeck (1629). Next year he succeeded Wallenstein as commander-in-chief of the imperial forces, and took by storm the town of Magdeburg (q.v.; 20th May 1631). The unheard-of atrocities which he allowed the Croats and Walloons of his army to perpetrate on this occasion have cast a foul stain upon his reputation not to be blotted out. From this time fortune deserted him, for his next opponent was the great Gustavus Adolphus, who completely routed him at Breitenfeld (17th September 1631); and, though in the following spring he obtained a slight success over the Swedish general Horn, the king speedily forced him to retreat behind the Lech in Bavaria, and (5th April) forced the passage of the river right in his front, after a desperate conflict, in which Tilly received his death-wound. He was carried to Ingolstadt, where he died, 20th April 1632. Tilly was small and meagre, with fierce eyes and a stern countenance, sober and continent, a despiser of luxury and wealth. His zealous support of the Catholic party was entirely founded upon fanatical zeal for the supremacy of a religion which he regarded with more than monkish devotion.

Til-seed. See Sesame.

Tilsit, a town of the province of East Prussia, on the left bank of the Memel or Niemen, 65 miles NE. of Königsberg by rail, with some miscellaneous manufactures, and an active trade in timber, corn, hemp, flax, butter, &c. Here was signed, on an island in the river, the treaty of 1807 between Alexander I. of Russia and Napoleon, which marked the lowest depth of Prussia's humiliation, and took away (till 1815) half of her territory (see Napoleon). Pop. 23,500.

Timaru', a port in the south island of New Zealand, 100 miles SW. of Christchurch; pop. 3800.

Timber. In the United States there are 300 species of trees the smallest of which grows to a height of 30 feet. In South America the number is much greater, and India possesses about 900 species of timber-trees. The species in England do not exceed thirty, and in France or Germany there are only a few more. Yet, though the kinds of wood are so much more limited in European countries, there are almost as few in general use in the United States as in Europe. The smallness of the number of species of timber known to commerce is at first glance very remarkable, but it is accounted for in this way. The great consumpt of timber is for architectural and other constructive works which are usually carried out on a scale of some magnitude, and for such purposes large quantities of the kind or kinds chosen are required. It is very desirable, therefore, that the wood selected should be plentiful, durable, more or less easily worked, fairly uniform

in quality, and moderate in price. As yet the very useful timbers have been obtained from gregarious species of trees growing in the forests of the north temperate regions of the globe, and the most important of these are a few kinds of fir and pine. From the tropics, where the social species are fewer, come the harder, heavier, and more richly coloured or figured kinds, some of which are used in Europe and North America only for furniture and decorative purposes. Some of these tropical woods are, however, of extraordinary strength, and possess other valuable properties which will bring them sooner or later into use for building purposes. This is all the more certain to be the case as both in North America and in Europe the forest-covered land is being stripped of its best timber at a rapidly increasing rate. Trees are of such slow growth that it takes many years before they are large enough to yield useful timber; so that when the primitive forests of a country are once cut down the keeping up of a supply by planted trees is a very difficult matter.

Chief Commercial Timbers.—The following are the best known and most used timbers in Great Britain. Baltic Redwood (*Pinus sylvestris*), perhaps the most generally useful of all, is employed for roofing and flooring, and often for all other internal and external wood-work of better-class houses and other buildings. It is also used for paving streets and many other purposes. This wood in the cut state is called 'yellow deal' in England. American Yellow Pine (*Pinus strobus*), called white pine in its native country, is also very largely imported for the internal joiner-work of buildings, parts of furniture, &c., but it is not suited for external work. Like the last, it is an excellent and easily worked timber. Baltic White-wood (*Abies excelsa*) has for a considerable number of years taken the place of redwood for joists, flooring-boards, roof-timbers, &c. It is a distinctly inferior wood. American Pitch Pine (*Pinus rigida*), found over a large extent of country in the eastern states, is an important timber. It has been much used in England for open roofs and for the whole of the wood-fittings of churches, halls, and the like. The annual rings of this wood are strongly marked, so that its planed surface looks striped. It can be got of large scantling, and is a heavy and highly resinous, but not very easily worked wood. The Douglas or Oregon Pine (*A. Douglasii* or *Pseudotsuga Douglasii*) of North-western America, between 200 and 300 feet in height, yields a timber of great length without knots, suitable for masts, spars, and many other purposes. Under the name of Californian Redwood, the timber of *Sequoia sempervirens* has of late years been to some extent imported into Great Britain. Like the last, the tree is of great size, and the wood is easily got free of knots. It is of a pleasing red colour (most of the so-called red pine-woods are nearly white), and easily worked in the longitudinal direction, but difficult to cut clean across the grain. Another recently imported wood is the Kauri Pine of New Zealand. The Kauri (*Dammara australis*) is also a majestic tree, and the wood is highly prized for all general purposes in its native country. It seems to have some tendency to warp, but this may be owing to defective seasoning. We may mention among coniferous woods that of the Deodar (*Cedrus Deodara*), which, although not used in Great Britain, is extremely durable, and of great importance in Northern India.

Among the more important American coniferous timbers, some of which have been already referred to, are the White Pine (*Pinus strobus*), called in England yellow pine; the Yellow Pine of the eastern states (*Pinus mitis*); the Hemlock; the Black Spruce; the Douglas Pine; Californian Redwood; the White Cedar (*Chamæcyparis thyoides*); the Red Cedar (*Juniperus virginiana*); and the Larch or Tamarack (*Larix americana*). See CEDAR, SEQUOIA, FIR, and PINE.

Of timbers from dicotyledonous or, as they are sometimes called, foliaceous trees oak is the most important. The oak timber grown in the north of Europe is obtained from two or three varieties of one species of Quercus, or from distinct but closely allied species (see OAK). The timber possesses in a high degree the useful properties of a hardwood. It is strong, tough, elastic, and not too heavy. Its specific gravity averages about ·800. Few woods are more durable or less affected in exposed situations by alternations of wet and dry weather. It is still used largely in shipbuilding and for many purposes in civil architecture, but for the latter it is much more expensive than pine-wood. Oak has the defect of rusting iron which pierces it or which is in contact with it. One or two American oaks also yield valuable timber. Teak (q.v.), from an Indian tree, is next in importance to oak as a constructive timber. It has just the opposite effect upon iron, as it protects the metal from rust, a property which gives it great value as a backing for the armour-plating of ships. Teak is neither quite so hard nor so strong as oak, but it is as difficult to cut with tools, and it is rather lighter when thoroughly seasoned. Besides its extensive use in shipbuilding, it has been of late years used for external architectural work. Elm (q.v.), though of much less consequence than oak as building timber, is nevertheless a good deal employed for engineering purposes; it is also used in shipbuilding for keels and other parts under water. Elm is only of great durability if kept either quite dry or constantly wet. For other timbers belonging to the same great class of trees, such as ash, beech, hornbeam, sycamore, lime, and birch, which have more restricted applications, see their respective heads. In the south of Europe the timbers of the Chestnut (*Castanea vesca*) and the Walnut are extensively used.

There are a few exceptionally remarkable timbers, which may just be named. Greenheart (q.v.), which is of extraordinary strength, is believed to contain some principle which resists the attacks of boring-worms when used for piles. Sabicu (*Lysiloma sabicu*), which is plentiful in Cuba, is another immensely strong wood. Both these timbers are heavier than water, and are used in shipbuilding. The Jarrah Wood (*Eucalyptus marginata*) of Western Australia is believed to be extremely durable for sleepers and paving blocks. Recently a few of the streets of London have been paved with it. Lignum Vitæ (*Guaiacum officinale;* see GUAIACUM) is of all woods the one which comes nearest to a strong metal in resistance to tear and wear.

Furniture and Ornamental Woods.—Mahogany (q.v.) is by far the most important of furniture-woods, and it has many minor applications as well. Perhaps no other timber has such valuable properties for the construction of cabinets, sideboards, tables, or casing of any sort. For a hardwood it is easily worked; it is close-grained, takes a fine polish, and is very durable; if well seasoned it is not apt to warp, shrink, or crack, and its colour improves with age. Some pieces of finely 'curled' or figured mahogany bring a very high price. Oak, though also an excellent wood for furniture, is more difficult to season, more laborious to work, and less easy to obtain free of defects. The Black Walnut (*Juglans nigra*) of Canada and the United States is much used for furniture. It is of a pleasing dark colour, and comes near Spanish mahogany in suitability for cabinet work, but it is not so hard. Italian or Circassian Walnut (*Juglans regia*)

is harder, and as a rule much more richly figured. It has been used for centuries for carving and furniture in Italy and other European countries. Much old walnut furniture is badly 'worm eaten.' Brazilian Rosewood (see ROSEWOOD), the product of a much smaller tree than any of the above, is a strong, hard, heavy material, but fairly easily worked. It is of a dark, rich brown colour, with beautiful streaks and cloud-like markings of a still darker tint, which more nearly resemble those of a coloured marble than any other known wood. It has been long used in Europe for costly furniture. Satinwood (q.v.), of which there are two kinds much the same in appearance, is something like rosewood in hardness and fineness of grain. Owing to their closeness of grain neither holds glue well. Except that it is of a different and much lighter colour, the figure of satinwood much resembles the 'curl' of mahogany. Ebony (q.v.) is another of the costly cabinet woods which is also hard and heavy. It is particularly close in the grain, so that it is suitable for drawing instruments as well as for cabinets, caskets, and the like. Ebony is black or nearly black in colour, and has been prized for making furniture with ivory and other 'inlays' from ancient Egyptian times. Beautiful work of this kind is still made in Paris. The strikingly mottled Calamander Wood of Ceylon and the fine Marble-wood of the Andaman Islands are both from ebenaceous trees. Among the very beautiful and for the most part costly woods used only for veneering and inlaying furniture and small ornamental articles are Tulip-wood (*Physocalymma florida*), Snake or Letter Wood (*Brosinum aublctii*), Purple Heart (*Copaifera Martii*), and Zebra-wood (*Connarus guianensis*) from the tropical parts of America; to which may be added Amboyna Wood from Singapore. *Bird's-eye Maple*, a beautifully spotted or 'eyed' light wood, is used in its native country (North America) for furniture, and was formerly much in favour for this purpose in England (see MAPLE). In the south of Europe the wood of the olive and of the orange are used for cabinet work. In Australia some species of Acacia, such as Black-wood (*A. melanoxylon*) and Myall-wood (*A. homalophylla*), which are dark woods, the former, especially, often beautifully figured, are used for furniture; so also are several other woods, including Forest Oak (*Casuarina torulosa*), Muskwood (*Olearia argophylla*), and Cypress Pine (*Frenela robusta*), a Queensland tree. Of late years, under the name of African Mahogany, the botanical source of which is still uncertain, a wood somewhat resembling ordinary mahogany has been imported in some quantity into England from the coast of Guinea, and seems to be coming into favour for some kinds of cabinet work.

Nature of Wood.—The stem or trunk of an ordinary exogenous tree consists of a central pith and rings or zones of fibro-vascular bundles (composed of numerous cell forms) through which medullary rays radiate (see STEM). In a growing tree of this class the new wood forms next the bark, and is called sap-wood (alburnum). Gradual changes occur in these annual rings or layers of new wood as they become older, and in time, which varies from one to many years, they get hardened or solidified into ripe-wood or heart-wood (duramen), of which all useful timber consists. These changes are of a chemical and physical character, and, although it is the hardening of the wood of a growing tree with age that gives it its technical value, yet the change is, physiologically, an incipient process of degradation which ends in decomposition. It is only in a few kinds of trees, however, that the decay of the wood is rapid. This duramen or heart-wood, when properly treated after felling, is generally of a lasting nature, and in the hardwoods especially is usually of a darker colour than the sap-wood; but in some pine-woods the sap-wood, soon after the tree is cut down, gets darker than the heart-wood, and is of a bluish or greenish colour.

The properties of wood depend partly upon the mode of union of the fibres, and partly upon the constituents, such as gum, resin, tannic acid, &c., which occur in the cellular and intercellular spaces. But there is also a small proportion of nitrogenous constituents which set up a kind of fermentation in damp wood, and especially in young spongy wood, exposed to the air, and are the cause of its decay. In other circumstances, however, even in the presence of moisture, but where the access of oxygen is prevented, some kinds of wood will keep for an enormous length of time. Pieces of wood have been taken out of the lignite beds of the newer geological formations which are scarcely distinguishable from sound timber recently cut. The timber used in the construction of a house or other building should be thoroughly dried before being put in, and air allowed to circulate about it. This is especially necessary with regard to joists and flooring near the surface of the ground, otherwise damp and want of ventilation will render them peculiarly liable to be attacked by Dry Rot (q.v.).

The apparent specific gravity of wood varies from 0·383 (poplar wood) to 1·333 (lignum vitæ), and perhaps some kinds are even denser. But the sawdust of nearly all woods is heavier than water, and the actual specific gravity (i.e. of the wood apart from enclosed air) is much the same in all. The quality and the apparent specific gravity of timber from the same species of tree often widely vary. Soil, climate, whether they grow in close proximity, and other conditions determine to a large extent the value of wood from trees of a like kind. For example, the timber of the Scotch fir (*Pinus sylvestris*) brought from the Baltic varies so much that the Swedish wood is only two-thirds the price of that which comes from Danzig, while the wood of the same tree grown in Scotland is of less value than either. With mahogany the qualities differ far more. Spanish or Cuba mahogany is of much greater value than, and sometimes twice as heavy as, Honduras or Bay mahogany from the same species of tree. Each of these varieties again is found to differ greatly in quality in different samples of the wood.

Seasoning of Timber. — Trees, and especially deciduous trees, should always be felled in winter, as in that season they contain the least amount of natural sap. They should not be allowed to remain long upon the ground where they are cut down, but, as soon as possible, the logs ought to be stacked with packing pieces between them, to allow the sap freely to evaporate. They should also be covered in from the weather. When the logs are cut up into planks or boards these are usually in the first place laid horizontally, with laths or fillets between them, and allowed to remain in this position for six months completely protected from rain. Afterwards they are placed for the same length of time in a vertical position on racks, and kept a little apart. Most ordinary woods require this length of time to season them properly in a natural way, although some are ready for use sooner than others. The seasoning of timber can be hastened by steaming or boiling it, or, in the case of planks and thin cut wood, by placing it in hot air chambers. Natural seasoning is, however, by far the best. For cabinet work and the better kinds of joinery the naturally seasoned wood is, just before being used, usually put for a week or ten days in a stove heated to about 120° F. The thorough seasoning of wood

is of great importance, but too frequently is only partially effected.

Preservation of Timber.—For the external woodwork of buildings oil-paint is usually employed, and the painting should be renewed every four or five years. Wooden ships and boats are coated with tar or pitch. But for such purposes as pavement, sleepers, piles, &c. treatment with certain chemicals which penetrate the wood more deeply has been proposed. Three methods of doing this have been chiefly tried, and of these the impregnation with bichloride of mercury is called Kyanising (q.v.); when sulphate of zinc is used the process is termed burnettising; and the third method—the only one extensively practised in Great Britain—is creasoting. The latter consists in steeping the wood in creasote oil, from 8 to 12 lb. being required for every cubic foot of timber. Since 1882 a new process introduced by Mr H. Aitken of Falkirk has been under trial—namely, the soaking of timber, according to its bulk, from two to twelve hours in melted naphthaline. This is a volatile substance, which must so far be against its efficiency, but the results of the experiments are said to give good promise of success.

The following statement gives the imports of timber into Great Britain for the year 1890: Fir (all coniferous wood), 6,530,165 loads, value £13,891,144; oak, 142,154 loads, value £809,893; teak, 60,182 loads, value £680,162; unenumerated, including staves, 480,349 loads, value £1,385,797; furniture and hardwoods, 122,361 loads, value £994,766: grand total, 7,335,211 loads, value £17,761,762. In 1897 the value was £22,990,000.

The exports of wood and its manufactures from the United States in 1890 reached $28,255,745; in 1897 the annual value (including furniture, &c.) was close on $40,000,000. The annual lumber product of the United States may be set down at nearly $700,000,000, and the manufacture (in some 25,000 mills, employing 150,000 hands) at $230,000,000. The principal lumber-producing region is now that of Michigan, Wisconsin, and Minnesota; but here, as in the older states, the forests are being rapidly and ruinously depleted, and ere long the United States will be compelled to fall back for its chief lumber supply upon the Pacific and Gulf states. The articles CANADA, NORWAY, &c. may also be consulted.

See ARBORICULTURE, BARK, BAST, WOOD, BORERS, BORING ANIMALS; Laslett, *Timber and Timber Trees* (1875); Gamble, *Manual of Indian Timbers* (1881); W. Stevenson, *The Trees of Commerce* (1888); Marshall Ward, *Timber and some of its Diseases* (1889); Hartig, *Timbers, and how to Know Them* (Eng. trans. 1890); Schlich, *Manual of Forestry* (1891).

Timbrel (Spanish *tamburil*), a small musical instrument, in use in ancient times, notably by Miriam after the passage of the Red Sea, which was carried in the hand, and was apparently quite similar to the modern Tambourine (q.v.).

Timbuctoo (native *Tumbutu*, Arab. *Timbukhtu*), a famous city of the Soudan, on the southern edge of the Sahara, lies about 8 miles north of the main stream of the Joliba or Upper Niger. It stands only a few feet above the level of the river, is about 3 miles in circumference, and at present without walls, though in former times it covered a much greater area, and was defended by walls. The houses are mainly one-story mud-hovels, but one of the three chief mosques is a large and imposing building, dating from 1325. The place stands on an important trade route between the interior and the west and south; and its importance has increased through the gradual extension of French influence hither (see SENEGAMBIA). Articles of trade are gold-dust, salt, kola-nuts, ivory, gums, ostrich-feathers, dates, and tobacco, exchanged for Manchester goods, mirrors, knives, tea, coral, &c. The town stands on the borders of various tribes and kingdoms—Sonrhai, Berbers, Tuaregs, Fulahs, Mandingoes, &c.; and amongst the 20,000 inhabitants of the place all these races are represented, with Arabs, Arabised Africans, and Jews. Timbuctoo was apparently founded in the 11th century, and first became known to Europeans in the 14th (Ibn Batuta was here about 1350); it has been visited by but six or seven Europeans, including A. G. Laing in 1826, Barth in 1853, Lenz in 1880, and Dubois in 1894. Timbuctoo, which was occupied by the French in 1894, has been besung by Tennyson and Thackeray. See SAHARA; and Dubois, *Timbuctoo the Mysterious* (trans. 1897).

Time. The earth's axial rotation is the phenomenon by which time is measured everywhere on the earth's surface (see DAY). Experiment and observation show that, if we assume the earth to rotate uniformly, there are many other phenomena which are as accurately isochronous in their periodicity. That is to say they pass again and again through all their phases in exactly the same interval of time as measured in terms of the earth's time of rotation. In the pendulum of a clock and the balance-wheel of a watch we have such isochronism very approximately realised (see HOROLOGY). A little consideration will convince us that the measurement of time is really a comparison of periodic sequences. We cannot conceive any other mode of marking off time intervals than by some kind of motion of a periodic character. Our practical unit of time is essentially terrestrial. We may, however, measure time in terms of a unit which could be as easily defined anywhere in known space as on the surface of our earth. The periodic time of a particular ray of light emitted by a universally distributed substance like hydrogen would be such a cosmic unit.

It has been long the custom among civilised races to divide the day into twenty-four hours, or rather into two sets of twelve hours, mean solar time (see DAY). Twelve o'clock noon corresponds to the meridian passage of the *mean* sun; and each day begins at twelve midnight. Now as we pass westwards the instant at which the sun crosses the meridian occurs later and later, as measured on a clock keeping, say, Greenwich time. That is, the noons at two places not situated on the same longitude line occur at different instants. Thus London and Dublin have different local times, the Dublin noon falling 25 min. 22 sec. later than the London (or Greenwich) noon. Similar differences exist for other parts of the United Kingdom, but within recent years, because of the development of rapid intercommunication by rail and steam, Greenwich time has gradually been adopted throughout Great Britain, and local times have practically ceased to exist. Similarly France has adopted Paris time as the civil time for the whole country.

Following the example of the United States, all countries are gradually adopting Standard Time. By this is meant time which differs from Greenwich mean time by whole hours. The globe is divided into zones of 15° or one hour breadth, the Greenwich meridian being in the centre of the zero zone. Thus Belgium and Holland keep Greenwich time; Denmark, Sweden, Switzerland, Austria, and Germany (Prussia temporarily excepted) keep the time of longitude 15° E.—i.e. one hour earlier than Greenwich. In North America again five zones are distinguished. Halifax falls within the time zone of 60° W. long. or four hours later than Greenwich; Montreal and New York fall within the zone of 75° or five hours west of Greenwich; and so on across the entire continent. New York, Chicago, Denver, and San Francisco may be mentioned as places whose times

change by one hour as we pass from one to the next succeeding. The corresponding times are distinguished as Eastern (67½—82½°), Central (82½—97½°), Mountain (97½—112½°), and Pacific (112½—127½°) times. Standard time in Japan is nine hours earlier than Greenwich time.

In the western parts of Canada the twenty-four-hour system has been adopted, under which four P.M. becomes sixteen o'clock, and so on. Steps are being taken to introduce it generally in India, Belgium, and the United States. It is of special convenience in the construction of railway time-tables; and it has the further claim that it has long been used by the Italians and by astronomers. The system of universal time, in which all places would keep Greenwich time, has a growing number of advocates. The adoption of such a system would be a little awkward at first to all who have got to think of twelve o'clock as being necessarily either noon or midnight; but a little experience would correct this.

Time is earlier or later than Greenwich according as the locality is east or west of Greenwich. Thus places lying close together but on different sides of the longitude line of 180° differ nominally by a whole day in time. Sunday at the one place occurs simultaneously with Monday at the other. A vessel sailing eastwards across the Pacific has two consecutive days of the same name as it crosses the critical meridian, or in other words has one day of nearly 48 hours' length. On the other hand, a vessel sailing westwards in the same longitude drops a day. Until a few years ago the Philippine Islanders held their Sunday on the day which was Monday to the inhabitants of Borneo. This arose from the historic fact that the Philippines were discovered by the Spanish voyagers coming from the east round Cape Horn; whereas Borneo was discovered by the Portuguese coming from the west. The matter is put most simply thus: To the eastward-bound traveller sunrises come at shorter intervals than to the stationary observer, while to the westward-bound traveller they come at longer intervals. Thus after one complete circuit the former traveller has experienced one sunrise more, and the latter one sunrise less, than has the stationary observer in the same lapse of time.

For sidereal time, see DAY; see also the articles on Astronomy, Calendar, Chronology, Clepsydra, Dial, Hour, Hour-glass, Latitude and Longitude, Month, Period, Seasons, Year. For the philosophical theories of time, see PSYCHOLOGY, Vol. VIII. p. 475. When it is twelve o'clock noon, Greenwich mean time, the hour (local time) at various important places on the globe is as follows:

Auckland, N.Z.	11 h. 39 m.	P.M.	New York	7 h. 4 m.	A.M.
Bombay	4 51	P.M.	Paris	0 9	P.M.
Calcutta	5 53	P.M.	Peking	7 46	P.M.
Cape Town	1 14	P.M.	Quebec	7 15	A.M.
Dublin	11 35	A.M.	St Petersburg	2 1	P.M.
Edinburgh	11 47	A.M.	San Francisco	4 23	A.M.
Melbourne	9 40	P.M.	Sydney	10 5	P.M.

Times, THE, is a London daily paper, frequently spoken of as the leading journal of the world. It was established in 1788 (see NEWSPAPERS). The founder, Mr John Walter (1739–1812), was not a printer or journalist by profession, but an underwriter at Lloyd's who had made a fortune and lost it in consequence of the capture by a French squadron of a fleet of merchantmen on which he had taken a large risk. In 1803 the management of the paper was transferred to Mr John Walter (1784–1847), the son of the founder, a man of exceptional talent, energy, and enterprise. He refused to accept the foreign news offered him by the government, and organised a system by which intelligence from abroad was more correctly reported and more rapidly transmitted to London than it ever previously had been. The capitulation of Flushing, the victory of Waterloo, and many other important events were made known to the English public before the arrival of government despatches. The *Times* earned a high reputation for independence by the opposition it offered to the ministry of Pitt. Mr Walter, after overcoming difficulties which would have disheartened most men, succeeded in 1814 in printing the *Times* by steam, a most important event in the history of printing (see Vol. VIII. p. 411). In 1816 Mr Thomas Barnes (1785–1841) became editor. As a leader-writer he was assisted by Mr John Sterling, 'the thunderer.' Mr Barnes's successor was Mr John T. Delane (q.v., 1817–79), then a young man fresh from Oxford. The new editor wrote no articles, but he read all important matter printed for publication; and one of his chief tasks during the thirty-six years of his editorship was to make the leaders of able specialists reflect the ideas, tone, and language of the best London society. It was he chiefly who obtained for the *Times* leaders the reputation of being models of English style. In 1847 Mr John Walter (born 1818), third of the name, for twelve years member for Nottingham, and then from 1859 till 1885 for Berks, succeeded his father as proprietor. He inherited the enterprising spirit of his family. In his time the railway and electric telegraph revolutionised newspaper management, and no journal so rapidly and successfully adapted itself to the new conditions as the *Times*. The most prominent assistant of Mr Walter in this work was Mr John Macdonald (1822–89), for many years manager of the paper. He combined literary ability, business experience, and great administrative capacity with high inventive talent as a mechanical engineer. Under his able guidance, and at enormous expense, experiments were conducted which brought to perfection in 1860 the art of printing from stereotypes, and in 1869 'the Walter press' (see Vol. VIII. p. 412). In many ways the *Times* has won the confidence of the mercantile public. In 1841 it was the means of detecting a conspiracy by which London bankers would have been defrauded to the amount of one million sterling, but it had in consequence to defend an action at law. The merchants and bankers of London raised a sum to pay the costs, which, on their offer being declined by Mr Walter, was employed to found two scholarships at Oxford and Cambridge, and to erect two tablets recording the facts, one in the *Times* office, and the other in the Royal Exchange. The chief event in the recent history of the paper was the 'Parnellism and Crime' articles (see Vol. VII. p. 780). Mr Delane was succeeded as editor by Professor Thomas Chenery (1826–84), and under him and his successor, Mr George Earle Buckle, the *Times* has maintained its reputation as the leading newspaper. The telegraphic foreign news, necessarily ephemeral, has been supplemented by well-digested articles, yearly summaries, notices of the best English and foreign books, &c. These, with tables of contents appearing in each number, and an index published separately (since 1867), now make a file of the *Times* one of the best and most accessible books of reference.

See *Times* Centenary in *Times* of 1st January 1888, and Chambers's *Book of Days* (vols. i. and ii.).

Time-tables. See BRADSHAW'S RAILWAY GUIDE.

Timoleon, liberator of Sicily, belonged to a noble family of Corinth, and was born there in the later half of the 4th century B.C. So ardent was his love of liberty that, if he did not himself slay his brother Timophanes, he saw him slain without dissatisfaction, for attempting to enslave the state. In 344 he was sent to Sicily at the prayer of the

Greek cities there to save their liberties and repel the Carthaginians. He landed at Tauromenium, overthrew Hicetas, tyrant of Leontini, who was striving to drive Dionysius out of Syracuse, and by 343 had possession of Syracuse itself. Hicetas now induced the Carthaginians to send a huge army into the island, but Timoleon marched to meet them with 12,000 men, and routed them though seven to one on the river Crimissus (339), the gods themselves showing him signal favour by driving a blinding hail-storm right into the faces of the enemy. The Carthaginians were now fain to make a treaty by which they confined themselves to the west of the Halycus. He next drove out all the tyrants, and restored their freedom to the Greek cities of Sicily, then settled quietly as a private citizen in Syracuse, enjoying the love and admiration of the whole Greek world until his death in 337. Holm, the German historian, calls Timoleon the Garibaldi of antiquity; and the comparison does justice to his daring, his honesty of purpose, and his force of character, hardly to his wisdom and political foresight. His story was written by two contemporary writers, Timæus and Theopompus, who supplied the materials alike to the extant works of Diodorus Siculus and Plutarch. The latter's life is one of his masterpieces. An excellent edition is that by Dr Holden (Camb. 1889).

Timon, the misanthrope, was a native of Athens, and a contemporary of Socrates. The little that is known concerning him is learned chiefly from Aristophanes and the other comic writers who attacked him. Disgusted with mankind on account of the ingratitude of his early friends and companions, he lived a life of almost total seclusion from society, his only visitor being Alcibiades. Lucian made him the subject of a dialogue; but his name survives best in Shakespeare's play, the basis of which was the version of the story given in Painter's *Palace of Pleasure*.

This Timon must be distinguished from Timon the *Sillographer*, a Greek poet and philosopher, who was a scholar of Pyrrho, flourished about 280 B.C., lectured at Chalcedon, and spent his latest years at Athens. There are extant some fragments of his *Silloi*, a series of sarcastic hexameters upon Greek philosophers.

Timor, the most important of the chain of islands which stretch eastward from Java, has a length of 300 miles, an area of 12,264 sq. m., and pop. of about 500,000. A chain of wood-clad mountains runs throughout its entire length; one peak, Allas, near the south coast, being 11,500 feet in height. It is less volcanic than its smaller neighbours of the Sunda group, but it contains some quiescent or extinct volcanoes. Magnetic iron, porphyry, gold, copper, and sulphur are found. Otherwise the natural wealth of the island is not great, the comparatively dry climate producing a much less luxuriant vegetation than in Java. The exports are mainly maize, sandalwood, wax, tortoise-shell, and trepang. Separated from the Australasian region by the Arafura sea, the island shows few Australian types amongst its fauna and flora, which resemble those of Java, Celebes, and the Moluccas. The population is mainly Papuan, mixed with Malay and other elements. The smaller western portion belongs to the Dutch, with its capital at Kupang; the eastern part is Portuguese, capital Deli; but native chiefs really govern the island.

See Wallace's *Australasia* (1878), Forbes's *Eastern Archipelago* (1885), and Bastiat's *Indonesien* (1885).

Timor-Laut, or TENIMBER, a group of three islands, east of Timor, extending about 100 miles in length, and 2263 sq. m. in area. Unlike Timor, these islands are mainly coralline and correspondingly low-lying, though there is one extinct volcano 2000 feet high. Fauna and flora partake of Malay and Australasian characters. The natives—some 25,000 in number—are of Papuan stock. The islands belong to the Dutch residency of Amboyna. See the books cited at TIMOR.

Timothy and Titus, EPISTLES TO. The first and second Epistles to Timothy, along with the Epistle to Titus, make up the three so-called 'Pastoral Epistles,' whose claim to have been written by the apostle Paul has been unanimously recognised by Catholic tradition since at least the end of the 2d century. They owe the name by which they are collectively known to the fact that they purport to be addressed by the apostle in his old age to his younger companions, Timothy and Titus, with reference mainly to the discharge of the pastoral office; but even apart from this leading feature they are allied to each other in matter and style with special closeness, while at the same time they are separated from the rest of the 'Pauline' writings by their lateness of date, as well as by certain peculiarities common to all three. These peculiarities appear in their attitude alike to the doctrine and to the polity of the church. As regards doctrine, the writer has no longer, properly speaking, anything new to say; the doctrine of the church is no longer in course of discovery and delivery, but has been already exhaustively revealed and definitely fixed. The motto is 'guard the good deposit' (2 Tim. i. 14, R.V. margin), keep 'the right way,' 'the sound doctrine,' 'the sound words.' As Sabatier says: 'With the Epistle to the Philippians the living progress ceases; with the pastoral letters the conservative tradition begins. Paul's doctrine is there; but the soul which sustained and vivified it appears already to have left it. . . . We have reached a point of arrest.' Along with the rise of this conservative tradition a new conception of the function of the church as the 'pillar and stay' of the 'common faith' begins to make its appearance. The church had already of course existed as a visible society and organisation, with special officers for the functions of discipline and administration; and it seems an error to suppose (as has often been done) that even with regard to church government the pastoral epistles contain anything definitely new, such as the germs of monarchical episcopacy. Nevertheless 'the church is no longer identical with "them that are being saved" or "the elect;" it is compared to a "great house," which contains "vessels, some unto honour and some unto dishonour." It is, in other words, no longer an ideal community, the "Israel of God," but a visible society. And being such, its organisation had come to be of more importance than before,' especially in the matter of maintaining and transmitting orthodox belief. Apart from these peculiarities, which are rather to be felt than described, the pastoral epistles are separated from all the others attributed to the apostle Paul by their language and phraseology. They contain a great number of words which do not occur in the other 'Pauline' writings, though met with elsewhere in the New Testament; many of the most marked expressions of Paul are absent; his characteristic particles have disappeared and given place to others; the structure of the sentences is quite different.

External and internal evidence alike go to show that all three epistles belong to nearly the same date; and it is now agreed with practical unanimity that this date cannot have been earlier than the Neronian persecution (64 A.D.). Modern discussions have made it clearly impossible to assign them to any period covered by the book of Acts. The stay of Timothy in Ephesus postulated by 1 Tim.,

the captivity of the apostle after having been recently at Troas, Corinth, and Miletus, which is presupposed in 2 Tim., and his visit to Crete and proposed sojourn in Nicopolis (Epirus) which are mentioned in Titus, all require us to assume a continued activity of the apostle for an indefinite period after his first Roman imprisonment, an activity, however, of which (apart from the pastoral epistles themselves) tradition knows nothing. Assuming the genuineness of all three, the order in which they were written must have been 1 Tim., Titus, 2 Tim. Modern criticism of the pastoral epistles may be said to have begun with Schleiermacher, who accepted 2 Tim. and Titus as genuine, but thought 1 Tim. to be a non-Pauline compilation from the other two. Eichhorn on chronological and philological grounds argued that none of the three was by Paul, but did not deny that they belonged to the immediate school of the apostle. Baur's criticism was much bolder, assigning them to the middle of the 2d century, when the utility and necessity of a stricter church organisation in order to combat Gnosticism had begun to be felt. Baur detected distinct allusions to Marcion in 1 Tim. vi. 29; Titus, iii. 9. The most important item of external evidence against their genuineness is the fact that Marcion knew of only ten epistles of Paul. Marcion's information may have been defective, but so far as we know he was not wanting in candour or ingennousness. To sum up briefly the present state of criticism, the pastoral epistles are admittedly very late; but how late is practically impossible to say with our very imperfect knowledge of the state of the church during the decades immediately following the year 64 A.D. It cannot be said to have been made out, or nearly made out, that they are so very late as Baur supposed. But on the other hand all that the apologists can say is that their Pauline authorship is not inconceivable, especially if we suppose the apostle to have lived and laboured a good while after the Roman captivity recorded in the Acts. 'Conceivability' in such matters of course depends a good deal on the individual critic's feeling for language, style, 'atmosphere,' and such like criteria. At the very least we may safely say that they contain elements of a Pauline tradition, and more or less vivid recollections of the substance of his correspondence with Timothy and Titus; possibly they embody some verbatim fragments—e.g. 2 Tim. i. 15–18; iv. 9–21.

See the commentaries of Huther (in Meyer's *Commentar;* Eng. trans.), Alford, Wace (in *Speaker's Commentary*), Weiss (new ed. of Meyer), and Soden (in Holtzmann's *Handcommentar*). For the criticism of the epistles the monograph of Holtzmann is the fullest (*Die Pastoralbriefe kritisch u. exegetisch behandelt*, 1880). Baur's work, *Die sog. Pastoralbriefe des Ap. Paulus* (1835), is still of value. See also the New Testament introductions of Hilgenfeld, Reuss, Salmon, Weiss (Eng. trans.), and Holtzmann; Sabatier's *L'Apôtre Paul* (Eng. trans. 1891), Farrar's excursus to his *Life of St Paul*, and Hatch's article 'Pastoral Epistles' in *Ency. Brit.*

Timothy Grass, the name commonly given to *Phleum pratense*, a grass much valued for feeding cattle. It first received the name Timothy Grass in America, from the name of a person who did much to promote its cultivation there. Along with the other species of the genus, it often receives also the English name of Cat's-tail Grass or Meadow Cat's-tail. The genus Phleum is distinguished by a panicle so compact as to resemble a close spike, single-flowered spikelets, with two nearly equal acuminate or almost awned glumes, two awnless palea, and the seed free. The species are mostly natives of Europe; a number of them are British, but the Timothy Grass alone is of any economical value. It varies very much in size according to soil and situation, succeeding best in moist, rich soils. It is very extensively cultivated both in Britain and in America. It has strong culms, attaining a height of 4 to 5 feet, but is tender and nutritious, and much relished by cattle. It is perennial, but springs up rapidly, even in the year in which it is sown. Its spike-like panicle, from the form of which the name Cat's-tail has been given, is cylindrical, and often of several inches in length. The seed is very small. *Phleum nodosum* is a very similar species, perhaps a mere variety, with the lower part of the culm prostrate and swollen into knots or bulbs, the spike much smaller than in *P. pratense*. It is a very inferior grass, and is found only on dry soils.

Timothy Grass (*Phleum pratense*).

Timur. See TAMERLANE.

Tin (sym. Sn; atomic weight, 118·76; sp. gr. 7·3). Either tin itself or an ore of it must have been known from a very early time, as all ancient bronze objects contain a certain proportion of this metal (see BRONZE, and METALLURGY). Ingots of metallic tin and articles made of it have been found in several of the Lake-dwellings (q.v.) discovered on the continent of Europe. It was therefore smelted more than 2000 years ago. Pliny refers to Cornish tin, and the metal is known to have been taken to Italy through Gaul after the Roman conquest of Britain. See also CASSITERIDES.

Tin has a silvery-white colour with a faint yellow tinge, and objects made of it have a brilliant lustre when new or newly cleaned. It does not tarnish readily. When melted and slowly cooled it is obtained in crystals of considerable size. A bar of the metal with a cross section of say a quarter of an inch in area is easily bent, and during the bending emits a crackling sound due to the crushing together of its crystalline particles. Tin is of greater hardness than lead, but it is softer than gold. It is very malleable, and can be beaten into foil as thin as $\frac{1}{1000}$ of an inch. Its tenacity is not great, a wire of the metal $\frac{1}{12}$ of an inch thick breaking with a weight of 56 lb. At the temperature of about 442° F. (228° C.) it becomes brittle enough to be reduced to powder by hammering. At St Petersburg a bar of the metal has been known to break up into small granular particles during a very low winter temperature. The same result may be obtained by lowering its temperature artificially to − 39° C.; at least it is very brittle at this temperature. Tin conducts heat and electricity moderately well. Its melting-point is 455° F. (235° C.), being considerably under that of lead. It is volatile, but only at a very high temperature. Among common metals it is least acted on by air and water, hence its utility for a great many purposes. With the exception of nitric, no acid attacks tin vigorously unless with the aid of heat.

There are two oxides of tin—viz. stannous oxide and stannic oxide, with corresponding series of salts. *Protoxide*, *monoxide*, or *stannous oxide*, SnO, is prepared by first adding to dichloride of tin a solution of carbonate of soda. The white precipitate produced is the hydrated oxide, which absorbs oxygen from the air; but when heated to

redness in a current of carbonic acid, or dried in a stream of this gas in the absence of air, anhydrous stannous oxide is obtained as a black powder. The hydrated oxide dissolves readily in acids, but these act more slowly on the anhydrous oxide.

Dioxide, binoxide, or *stannic oxide,* SnO_2, forms on the surface of tin kept at a heat above its melting-point with access of air. This is removed as it forms, and again heated to completely oxidise any of the finely divided tin mixed with it. Stannic oxide is also produced when tin is acted on by nitric acid. It is this oxide of tin which, when finely ground, forms the hard white material known as Putty Powder (q.v.), and used for polishing hard stones and other bodies. It also enters into the composition of one kind of opaque white glass. Stannic oxide occurs in nature as the mineral cassiterite, the ordinary ore of tin.

Hydrated stannic oxide or *stannic acid,* H_2SnO_3, is obtained by adding carbonate of lime to tetrachloride of tin; also by adding an acid to stannate of potash or soda. It is a white gelatinous substance, acting as a base by combining with acids, as in tetrachloride of tin, or as an acid combining with bases to form salts, stannate of soda (sodium stannate), Na_2SnO_3, for example. But there is another state in which this acid occurs with quite different properties, when it is termed *metastannic acid.* If tin is placed in nitric acid of about 1·3 sp. gr., it is rapidly converted into a white crystalline powder having the same composition as stannic acid, but represented by the formula of this acid multiplied by five to account for its salts having only $\frac{1}{5}$ the quantity of base; thus, metastannate of soda is $H_8Na_2Sn_5O_{15}$. Metastannic acid is insoluble in all ordinary acids (except undiluted sulphuric acid), but it is readily soluble in alkalies, and the salts thus formed are converted into stannates by heating with excess of the base. The stannate of soda is used in calico-printing.

Sulphides of tin.—The monosulphide of tin, or stannous sulphide, SnS, is black, and stannic sulphide, SnS_2, yellow, the latter being soluble in sulphide of ammonium. Under the name of *mosaic gold* stannic sulphide is used as a bronze powder for bronzing articles made of plaster of Paris, wood, &c. There is a native sulphide of tin and copper.

Dichloride of tin or *stannous chloride,* $SnCl_2$, is obtained by boiling the granulated metal with moderately strong hydrochloric acid. It crystallises with two molecules of water. A solution of this salt, unless made slightly acid, soon shows a slimy whitish deposit by which it is easily recognised. It is a powerful deoxidising agent, persalts of iron being converted into protosalts when it is added to their solutions, and with other salts, such as those of mercury, causing a deposit of the metal. It is used as a test for gold in solution, giving a purple colour.

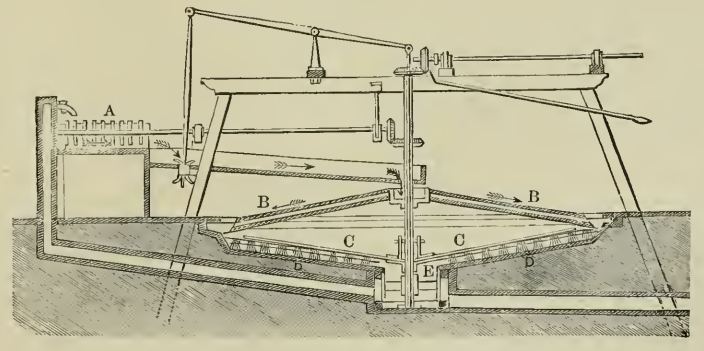
Tetrachloride of tin or *stannic chloride,* $SnCl_4$. This salt is formed when chlorine gas is passed over melted tin. It is also got as an anhydrous volatile liquid when powdered tin is distilled along with corrosive sublimate. It fumes when it meets the air, and has long been known as *fuming liquor of Libavius.* A more or less pure salt of this kind is used by dyers, made by dissolving tin in a mixture of hydrochloric and nitric acids. The chlorides of tin, like the stannate of soda, are used as mordants in dyeing. All the salts of tin give a bead of the metal when heated on charcoal in the inner blowpipe flame.

Ore and Smelting.—*Tinstone* or *cassiterite,* which is the binoxide of tin (often found in a nearly pure state), is the chief ore of the metal. Nearly all the tin of commerce is obtained from it. This mineral is usually of a dark-brown or blackish colour, but it is sometimes yellowish brown or gray. Its specific gravity is high—viz. from 6·3 to 7·1—and it is also very hard. It is found crystallised in quadrangular prisms, terminated by four-sided pyramids, and in more complex forms; and when pure consists of tin 78 and oxygen 22. Tinstone occurs in veins or lodes in granite or granitic rocks, gneiss, clay-slate, and mica-slate.

Wood-tin or *fibrous tin* is a fibrous form of cassiterite occurring in globular, botryoidal, or wedge-shaped fragments, usually of a small size. In colour and structure it has some resemblance to dry wood. *Stream tin* is again the same mineral found in the alluvial debris forming the beds or sides of streams. It has in course of time become separated by the disintegration of the veinstone, and is washed out of the gravel or debris.

The older tin-producing countries are England (Cornwall), Germany (Bohemia and Saxony), and, for small quantities, France and Spain, in Europe; Malacca, Banca, and some neighbouring islands in southern Asia; and Chili, Peru, Bolivia, and other South American states. The most important of recently discovered tin districts are in Australia, those in New South Wales and Victoria being as yet most productive. Tasmania also yields a considerable supply. In the United States, though none is yet largely worked, there are rich deposits of both vein ore and stream tin, from the opening up of which great results are expected. These occur at Harney Peak, South Dakota; Martha Cash, Virginia; Temescal, California; and a few other places.

Tin ore from the mine is subjected to a complicated series of dressing operations. The tinstone of Cornwall especially is associated with a large number of other minerals, which require to be as much as possible separated from it before smelting. Of these copper and arsenical pyrites and wolfram (when this is present) are got rid of by special chemical processes. For the mechanical dressing processes stamps, buddles, pulverisers, &c. are required, and these are noticed under METALLURGY. The following is a summary of the stages in the dressing of the ore: (1) it is reduced to grains by stamps; (2) a portion of the waste material is then removed by centre head and concave buddles (see figure); (3) more waste is next separated in the



Borlase's Concave Buddle—vertical section:

A, box with agitator: the ore is fed here; B, revolving spouts for distributing the ore at circular ledge; C, arms with sweeps; D, floor on which the washed ore settles; E, well into which waste and slime falls.

tossing tub; (4) at this stage the sulphur and arsenic are driven off by heat—calcining; (5) after the calcining the ore is reduced by a pulveriser, of which there are several kinds, to a fine sand; (6) the sand is then finally washed on slime frames or buddles to separate the 'black tin'—i.e. the pure, or comparatively pure, tin ore.

In order to separate the arsenic and sulphur which, in the form of arsenical and common pyrites so commonly accompany Cornish tin-stone, the ore in the fourth stage of dressing (see above) is calcined. There are two kinds of calciners in use—viz. Brunton's, which has a revolving circular hearth, with stirrers, and Oxland and Hocking's, the chief feature of which is a revolving iron cylinder, lined with firebricks. This cylinder is fitted up in a sloping position, with a fireplace at the lower end. The ore is fed at the top, and as it descends parts with the sulphur and with the arsenic, which, as 'crude arsenic' (arsenious acid), is collected in the specially constructed flues of a chamber in connection with the cylinder-furnace. See ARSENIC.

Tin ores which contain the mineral wolfram (tungstate of iron and manganese) are treated by a special process, patented by Mr R. Oxland of Plymouth. This mineral and tin ore are so nearly the same in specific gravity that no mechanical method of washing will separate them. Oxland's process consists in treating in an iron pan in a reverberatory furnace the tin ore with sulphate or carbonate of soda, for the purpose of converting the insoluble tungstate of iron and manganese into the soluble tungstate of soda, which is easily removed by lixiviation. The oxides of iron and manganese, which are left in a finely divided state, can then, from their lower density, be readily got rid of by washing. The tungstate of soda procured in the operation has been employed for rendering cotton cloths non-inflammable and as a mordant in dyeing and printing calico.

In England the dressed tin ore is reduced in a reverberatory furnace, somewhat similar to that used for smelting copper (see COPPER, fig. 1). It is mixed with one-fifth of its weight of anthracite coal, broken into small pieces, and a small quantity of lime or fluor spar to combine with siliceous matter in order to form a fusible slag. The heat is slowly raised with as little admission of air as possible, so as to maintain a reducing atmosphere. When the charge has been some hours in the furnace it is occasionally stirred to assist the aggregation and separation of the slag, and in about six hours the metal is ready to be run off. The tin flows out of the furnace by an aperture in the middle of one side—towards which all the rest of the bed slopes—into a cast-iron pot, from which it is cast into bars. The tin at this stage contains other metals, such as arsenic and iron, as impurities, so that it requires to be refined, and this is done by *liquation* and *poling*. The process of liquation consists in placing the bars of tin on the hearth of a furnace, such as has been described, and slowly heating them to just above the fusing-point, when pure or nearly pure tin melts and runs down the sloping furnace-bed into a cast-iron vessel, fresh bars being added until enough of the metal is collected. What remains on the hearth is a less fusible alloy of tin with arsenic, iron, and other metals. The nearly pure tin is kept by a fire in the melted state, and stirred up with a pole of green wood, the operation producing a current of gas that agitates the molten metal and causes a scum to rise to the surface, which is skimmed off. The tin is then run into moulds for the market, *grain-tin* being the name given to the best quality of the metal. It is known by its property of becoming brittle when heated to just below its melting-point, so that when it is then let fall from a height, or struck with a hammer, it breaks up into prismatic fragments. Banca tin is the purest kind made on a commercial scale, and is nearly chemically pure. English tin comes next to it as regards purity.

Applications.—The great consumption of tin is in the formation of alloys, such as bronze, gun-metal, Britannia metal, &c. (see ALLOY), and in the manufacture of tinned iron plates. In the form of an amalgam it is employed for 'silvering' mirrors, and as tinfoil for lining boxes and wrapping up perishable articles. The small gas-pipes of houses are best made of block-tin. Ordinary commercial tin tarnishes very slightly in the air, and is not acted upon by vinegar or the acids of fruits. It is consequently very suitable for coating the inside of cooking vessels, whether made of iron or copper. Large vessels for other purposes formed of these metals are also occasionally coated with tin. In some parts of India vases, jugs, and other useful and ornamental articles are made entirely of tin. The uses of some tin salts are noted above.

The quantity of tin ore raised in Cornwall amounted (with the trifling addition from Devon) in 1890 to 14,911 tons of dressed ore, yielding of metallic tin 9602 tons, the value of which was £937,760. In the same year the total imports into Great Britain were 2663 tons of tin ore, value £96,593, and 27,038 tons of metallic tin, value £2,547,416. In 1897 the quantity of tin yielded in Britain was only 4453 tons, value £291,336; the imports of tin in 1897 were valued at £1,623,798. Of the total, counting both ore and tin imports, the Straits Settlements furnished more than one-half.

See TIN-PLATE, and STANNARIES; P. W. Flower, *History of the Trade in Tin and Tin-plates* (1880); A. G. Charleton, *Tin-mining Abroad* (1884); and L. F. Blinn, *Companion for Tin-workers* (1891).

Tinamou (*Tinamus*), a South American genus of birds sometimes called partridges, but really more akin to bustards, and having affinities with the Rhea and Emu. *T. major* or *brasiliensis* is about 18 inches long.

Tincal. See BORAX.

Tinchebrai, a small town (pop. 2429) in the extreme north-west of the Norman department of Orne, where Henry I. (q.v.) of England defeated his brother Robert.

Tincture. See HERALDRY, Vol. V. p. 661.

Tinctures are defined by Sir Robert Christison to be 'solutions of vegetable and animal drugs, and sometimes of mineral substances in spirituous liquids.' The spirit most commonly employed is proof-spirit (see ALCOHOL, Vol. I. p. 133): sometimes rectified spirit is used, and occasionally ether. Ammonia is sometimes conjoined with the spirit, in which case the solution is termed an ammoniated tincture. The choice between proof and rectified spirit depends on their respective solvent powers over the active principles of the drugs employed. The ether and ammonia are principally used for their antispasmodic properties.

Tindal, MATTHEW, a notable deistical writer, was the son of the rector of Beerferris in South Devon, where he was born in 1656. He was educated at Lincoln and Exeter Colleges, Oxford, took the degree of B.A. in 1676, and was elected fellow of All Souls College. In 1685 he became a Doctor of Law; and after a brief lapse into Romanism during the reign of James II., reverted to Protestantism of a somewhat freethinking type. His first work, *An Essay concerning Obedience to the Supreme Powers* (1693), was followed by others on the powers of the magistrates in religious matters, on the liberty of the press, &c.; but it was not till 1706 that he attracted special notice, when the publication of his treatise on *The Rights*

of the Christian Church asserted against the Romish and all other Priests raised a storm of opposition. A perfect torrent of replies and refutations of this statement of state supremacy over the church poured from the press; but even a prosecution failed to prevent the appearance of a fourth edition in 1709, to which a *Defence* was added. On the Continent Tindal's work was quite differently received. Le Clerc praised it as one of the solidest defences of Protestantism ever written. In 1730, when he had nearly reached the age of seventy-three, he published his most celebrated treatise, *Christianity as old as the Creation, or the Gospel a Republication of the Religion of Nature*, which effectually settled the question of his religious creed. The design of the work, which was soon known as 'the Deist's Bible,' is to strip religion 'of the additions which policy, mistake, and the circumstances of the time have made to it'—in other words, to eliminate the supernatural element, and to prove that its morality, which is admitted to be worthy of an 'infinitely wise and good God,' is its true and only claim to the reverence of mankind. Tindal's purpose was rather constructive than destructive; and it was on this account that he called himself a 'Christian Deist.' Answers or refutations were issued by Waterland, Foster, Conybeare (afterwards Bishop of Bristol), Leland (q.v.), and others; the work itself was translated into German. Tindal died at Oxford, still a fellow of his college, on the 16th August 1733. See the article DEISM, and works there cited.

Tinder, an inflammable material, usually made of half-burned linen. It was one of the chief means of procuring fire before the introduction of chemical matches. The tinder was made to catch the sparks caused by striking a piece of steel with a flint; and the ignited tinder enabled the operator to light a match dipped in sulphur. This intermediate step was necessary in consequence of the impossibility of making the tinder flame. Partially decayed wood, especially that of willows and other similar trees, also affords tinder; and certain fungi furnish the German tinder, or Amadou (q.v.).

Tinea, the generic name of certain diseases of the skin caused by the growth of microscopic fungi. See under FAVUS, PITYRIASIS, RINGWORM.

Tineïdæ, a family of small Moths (q.v.).

Tinfoil. See FOIL.

Ting-hai. See CHUSAN.

Tinker's Weed (*Triosteum perfoliatum*, erroneously called Tinkar's-root), the Fever-weed, with purgative and emetic properties, so called after an 18th-century New England doctor.

Tinned Meat. See PRESERVED PROVISIONS.

Tinneh. See AMERICAN INDIANS.

Tinnevelli (*Tiru-nel-véli*), chief town of the British district of the same name, is situated 1½ mile from the river Tambraparni. The town of Tinnevelli is connected with the town and military station of Pallamcotta, on the opposite bank of the river, which is the administrative headquarters of the district. It contains a Sind temple and a Hindu college, and has a cotton-factory. It is an important Protestant missionary centre, and the terminus of the Tinnevelli branch of the South Indian Railway. Pop. 23,221.

Tinnitus Aurium is the Latin translation of, and ordinary medical term for, ringing in the ears. In most cases it is an unimportant symptom, depending on some local temporary affection of the ear, or on some disturbance of the digestive system with which the part of the brain, from which the auditory nerve springs, sympathises, or which excites the cerebral circulation (as often occurs in the morning after too liberal evening potations); but, as it is also a common symptom of organic disease of the auditory nerve, it may indicate a dangerous condition, or may be a prelude to complete deafness. Hence, although commonly of no consequence, it is a symptom that, especially if permanent, must be carefully watched. It may be readily induced for a few hours by a large dose of quinine, salicine, or their compounds. Tinnītus is of course the proper pronunciation, but in medicine it is usually called *tinnĭtus*.

Tino. See TENOS.

Tin-plate. The manufacture of this article forms a branch of the iron trade. The art of tinning plate-iron is said to have been invented in Bohemia, about the beginning of the 16th century, although the tinning of copper was known earlier. Tin-plate was first made in England about 1670. Sheet-iron for tin-plates is made either of charcoal-bar or coke-bar, which has been rolled with particular care, in order to avoid scales on the surface. Before tinning the plates are called 'black plates.' When the iron has been cut to the required size the plates are 'pickled'—i.e. they are immersed in hot sulphuric or hydrochloric acid which has been diluted by 16 parts of water to 1 of acid, the use of the acid being to remove all oxide. After this the plates require to be washed several times in water, and then annealed. The plates are next passed two or three times through chilled iron rollers highly polished with emery and oil, to give them a well-polished surface. Once more they are sent to the annealing furnace, passed again through dilute sulphuric acid, which is followed by another washing, but this time in running water, and then scoured with sand. This should leave them quite clean and bright.

Each plate is now put singly into a pot of melted grease (which has become sticky by use), and left till it is completely coated, after which the plates are taken in parcels and plunged into a bath of melted tin covered with grease, called the 'tin-pot.' The plates are afterwards put in parcels into the first of the two compartments of a vessel, where they receive a coating of purer tin than that of the 'tin-pot,' and are then withdrawn one by one, and wiped on both sides with a hemp brush, the marks of which are obliterated by another dipping in the second compartment of the 'wash-pot.' This last dipping also gives the plates a polish. The superfluous tin is removed by immersing the plates in a pot containing tallow and palm-oil, maintained at a temperature just high enough to allow the tin to run off. The final treatment consists in working the plates separately in troughs of bran with a little meal, and then rubbing them with flannel. Of late years tin-plates of mild steel have been manufactured, and for some purposes they are preferred to iron tin-plates.

There is a variety of tin-plates called 'terne-plates,' coated with an alloy of tin and lead, in which the proportions vary from 1 of lead and 2 of tin to 2 of lead and 1 of tin. Now 'tin-plates' are frequently made of steel.

The manufacture of tin-plates is chiefly carried on in South Wales and in the United States. In 1890 the total exports from Great Britain amounted to 421,797 tons, valued at £6,361,477; of this quantity 321,109 tons were sent to the United States. By the McKinley tariff of 1890 a high protective duty ($2\frac{2}{10}$ cents per lb.; lowered to $1\frac{2}{10}$; and again increased in 1897) was imposed on tin-plates imported into the United States, in order to protect the manufacture there. In 1895 English exports were 366,120 tons, value £4,239,193.

Tinsel, glittering metallic sheets, as of burnished brass, copper, or tin, almost as thin as foil,

and used in discs, patches, strips, or threads for giving clothing, &c. a sparkling appearance.

Tintagel Head, a cliff 300 feet high on the western coast of Cornwall, about 22 miles W. of Launceston, and but 6 miles from Camelford—the Camelot of Arthurian legend. Partly on the mainland and partly on the so-called island, almost cut off by a deep chasm from the rest of the promontory, stand the imposing ruins of the castle where King Arthur held his court. His spirit still hovers around the scene of his splendour in the form of the red-legged chough, a beautiful Cornish bird already rare in Leland's time. The oldest part of the existing ruins is the keep, apparently of Norman construction, but there need hardly be a doubt that a Saxon, and perhaps earlier a British stronghold occupied the same site. The castle was still habitable in 1360, when we read of its being provisioned.

Tintern Abbey, perhaps the most beautiful ruin in England, on the right bank of the Wye, in Monmouthshire, about 5 miles above Chepstow. The abbey was founded in 1131 for Cistercian monks, but the church, the finest part of the ruins, dates from the end of the following century. The length of the building is 228 feet; the style of architecture a transition from Early English to Decorated; the window-tracery is especially fine. But the greatest glory of Tintern Abbey is that its name is associated with Wordsworth's noblest poem, *Lines composed a few Miles above Tintern Abbey*—though, as every reader knows, the abbey itself is not mentioned in it. See works by C. Heath (1793), G. Cooper (1807), and W. H. Thomas (2d ed. 1845).

Tintoretto (in English often shortened into *Tintoret*), a great Italian painter, so called from the fact of his father being a dyer (*Tintore*), but whose real name was Jacopo Robusti, was born at Venice, 29th September 1518. He studied for a short time under Titian, but appears to have been for the most part self-taught. His motto was 'The design of Michaelangelo and the colouring of Titian;' and his aim was obviously to combine the dignity of the Florentine with the romanticism of the Venetians; but, though in the estimation of most of his contemporaries he succeeded, there has subsequently been diversity of opinion as to his merits. One of Ruskin's 'five supreme painters,' he was unquestionably a great master of composition, drawing, and colour; his conceptions are often grand and his chiaroscuro startlingly effective. But he was strangely unequal; some of his earlier pictures are very carefully finished, but his later ones are dashed off with a fatal haste that justifies the epithet *Il Furioso*, and the remark of Annibal Caracci, that 'if he was sometimes equal to Titian, he was often inferior to Tintoretto.' His portraits are generally admirable. Many of his pictures are of prodigious size. Of the innumerable pictures in the galleries that are attributed to him not a few are by other hands. Venice contains many undoubted specimens of his art; there are a number in England, including 'St George and the Dragon' in the National Gallery at London. Other famous pictures from his hand are 'Belshazzar's Feast, and the Writing upon the Wall' (fresco, for the Arsenal at Venice), 'The Tiburtine Sibyl,' 'The Last Supper and the Washing of the Disciples' Feet,' 'The Crucifixion,' 'The Worship of the Golden Calf,' 'The Last Judgment' (the last two immense pictures 50 feet high, and very splendid in conception), 'St Agnes restoring to Life the Son of a Prefect,' 'The Miracle of St Mark,' 'The Resurrection,' 'The Slaughter of the Innocents,' and the largest picture on canvas by any great master, the 'Paradise' (1558) of the Ducal Palace at Venice, 34 feet high by 74 long, and containing over 100 figures. Tintoretto, who ranks as the head of the later Venetian school, died 31st May 1594.

See, besides the general histories of painting, Crowe and Cavalcaselle's *Titian* (1876), Ruskin's *Stones of Venice* (1851-53), Osler's small monograph (1879), and the large one by F. P. Stearns (New York, 1895).

Tinworth, GEORGE, artist in terra-cotta, was born in London, 5th November 1843, the son of a poor wheelwright, and while working in his father's shop took to wood-carving of his own accord. In 1861 he found opportunity to get lessons in an art school at Lambeth, and in 1864 entered the Royal Academy schools. He soon began exhibiting figures and groups of figures at the Royal Academy, and in 1867 obtained a permanent appointment in the great Doulton art pottery. The works by which he became famous were mainly terra-cotta panels with groups of figures in high relief illustrating scenes from sacred history, which happily combine grace, strength, and dignity with originality of design, dramatic effectiveness, and devout feeling. An important example is the reredos in York Minster, with twenty-eight terra-cotta panels.

See an *Essay on the Life and Works of G. Tinworth*, by E. W. Gosse (1883), and *Strand Mag.* (Nov. 1891).

Tippecanoe, a river of Indiana, which rises in the northern part of the state, flows WSW. and S. 200 miles, and empties into the Wabash 10 miles above Lafayette. It is famous for the battle fought near its mouth, November 7, 1811, in which the Indians, under Tecumseh's brother, the prophet, were defeated by General Harrison.

Tipperah (*Tipura*), a district of the division of Chittagong (q.v.); Hill Tipperah being a small tributary state on its borders.

Tipperary, an inland county of the Irish province of Munster, touching Galway on the north and King's County, Queen's County, and Kilkenny on the east. Area, 1659 sq. m., or 1,061,731 acres, of which 843,837 are arable. The county of Tipperary for the most part lies in the basin of the river Suir (total length 85 miles); the Shannon touches the north-west border. The surface is generally level, but is diversified by several mountain ridges or groups. These mountains are the Galtees, rising to 3008 feet, Knockmeledown (2609 feet high), and Slievenaman on the south; Keeper Mountain on the west; and the Slievardagh Hills on the east. There is one very curious isolated height called the Devil's Bit, to which many popular legends attach. The soil of the plain is a rich calcareous loam, singularly fertile and productive, especially the district called the Golden Vale, in which stands the town of Tipperary. In geological formation the plain belongs to the great central carboniferous limestone district. Anthracite coal is worked; copper, lead, and zinc occur in smaller quantities; and slates and pipeclay are available. The principal occupation is agriculture, especially dairy-farming. The county, which since 1885 sends four members to parliament, is divided into two ridings, North and South, each of which is subdivided into six baronies. Pop. (1841) 435,553; (1871) 216,713; (1881) 199,612; (1891) 172,882, of whom 162,025 are Roman Catholics.

Anciently Tipperary formed part of the two distinct principalities of Ormond, or North Munster, and Desmond, or South Munster; after the English invasion Tipperary was formed into a county by King John in 1210; but the authority of the conquerors was long little more than nominal. Eventually it came to be divided between the Anglo-Norman families of Butler, which held Ormond, and Geraldine, to whom a portion of Desmond fell. The antiquities are numerous, as well Celtic as Anglo-Norman. In the latter the

city of Cashel (q.v.) is specially rich; and Holy Cross is a noble monastic ruin, whilst the castle of Cahir is a fine specimen of baronial architecture. There is a series of caves near the border of the county of Cork.

Tipperary, the county town, is 110 miles SW. of Dublin by rail, with a Catholic and a Protestant church, and has a noted butter-market; pop. 7274. In 1890, under the 'Plan of Campaign,' a 'New Tipperary' was founded to thwart the proprietor of the land on which Tipperary town is built, and opened on 12th April; but the scheme wholly collapsed in the course of the following year.

Tippermuir. See Montrose, p. 294.

Tippoo Sahib (more correctly *Tipú Sultan*), sultan of Mysore, and son of Hyder Ali (q.v.), was born in 1749. Efforts were made to carefully instruct him in the various branches of learning cultivated by Mohammedans; but Tippoo much preferred the practice of athletic exercises, and the companionship of the French officers in his father's service, from whom he acquired a considerable acquaintance with European military tactics. This knowledge he put to effective use during his father's various wars, by completely routing Colonel Bailey (1780 and 1782), and Colonel Braithwaite on the banks of the Coleroon (1782), though these were his only important engagements with the British forces in which he could boast of success. On the death of his father he was crowned with little ceremony, returning at once to the head of his army, which was then engaged with the British near Arcot. In 1783 he captured and put to death most of the garrison of Bednur; but news of the peace between France and England having reached his French allies, they retired from active service, and Tippoo ultimately agreed to a treaty (1784) stipulating for the *status quo* before the war. During the continuance of this peace he occupied himself in regulating the internal administration of Mysore, sent ambassadors in 1787 to France to stir up a war with Britain, and, failing in this, at length so far allowed his inveterate hatred of the English to overcome his judgment as to invade (1789) the protected state of Travancore. In the ensuing war (1790–92) the British, under Colonel Stuart and Lord Cornwallis, were aided by the Mahrattas and the Nizam, who detested their powerful and aggressive neighbour; and though the tactics of the sultan in laying waste the Carnatic almost to the very gates of Madras baffled his opponents for a time, he was ultimately compelled (1792) to resign one-half of his dominions, pay an indemnity of 3030 lakhs of rupees, restore all prisoners, and give his two sons as hostages for his fidelity. Nevertheless his secret intrigues in India against the British were almost immediately resumed; another embassy was sent to the French; and the invasion of Egypt by the latter in 1798 and Tippoo's machinations having become known to the governor-general almost simultaneously, it was resolved to punish the perfidious sultan. Hostilities commenced in March 1799, and two months after Tippoo was driven from the open field, attacked in his capital of Seringapatam, and after a month's siege slain in the breach at the storming of the fort (4th May). He was buried, during an appalling thunderstorm, in the mausoleum he had built for his father. His government of Mysore after 1792 was most oppressive, yet Tippoo was extremely popular, and was esteemed by the Mohammedans as a martyr. See L. B. Bowring, *Haidar Ali and Tipú Sultán* (1893).

Tipton, a town of Staffordshire, 4½ miles SSE. of Wolverhampton and 8½ NW. of Birmingham. It has important iron manufactures. Pop. (1851) 24,872; (1891) 29,314.

Tipula. See Daddy-long-legs.

Tiraboschi, Girolamo, the historian of Italian literature, was born at Bergamo, 28th December 1731, studied at Monza, became a Jesuit, and was afterwards appointed to a chair of Rhetoric at Milan, and in 1770 became librarian to the Duke of Modena. Here he wrote his *Storia della Letteratura Italiana* (13 vols. 1772–82), an elaborate, accurate, and exhaustive survey down to the close of the 17th century. A continuation embracing the literature of the 18th century was written by Lombardi. Tiraboschi died at Modena, June 3, 1794. Other works are *Vetera Humiliatorum Monumenta* (3 vols. 1766–68), *Biblioteca Modenese* (1781–86), and *Memorie Storiche Modenesi* (1793).

Tiree. See Tyree.

Tiresias, in Greek Mythology, figures as a famous prophet, who, according to one legend, was struck blind by the goddess Athena, because he had seen her bathing. Another legend represents Hera as depriving him of his sight because, being made arbiter in a dispute between her and Zeus, he had decided in favour of the latter; when Zeus as a compensation granted him the inner vision of prophecy, and prolonged his life for several generations. He is consequently prominent in many of the mythical stories of Greece, but at last found death after drinking from the well of Tilphossa. Tiresias is the theme of a fine poem by Lord Tennyson (1885).

Tirhut, formerly a district of Bengal, but in 1875 divided into the districts of Darbhangah (q.v.) and Muzaffarpur (q.v.).

Tirlemont (Flemish *Thienen*), a town of Belgium, in South Brabant, on the Great Geete, 30 miles ESE. of Brussels by rail. It has two fine churches of the 12th and 13th centuries, and manufactures of machinery, hosiery, flannel, leather, sugar, &c. Once a large and prosperous city, Tirlemont was ravaged by Marlborough in 1705; and here the French, under Dumouriez, defeated the Austrians in 1793. Pop. 16,500.

Tirnova, a town of Bulgaria, on the Jantra, 35 miles SSE. of Sistova, amidst strange limestone-rocks. It became in 1235 the seat of the Bulgarian patriarch, and has more than once served as the capital. Dyeing is carried on, and silk and coarse cloth are manufactured. Pop. 11,314.

Tironian Notes. See Shorthand, p. 415.

Tirso de Molina. See Tellez.

Tiryns, an ancient city of Argolis, in the Peloponnesus, situated a short distance SE. of Argos, about 3 miles from the head of the Argolic Gulf. In fable it was founded by Prœtus, brother of Acrisius, and predecessor of Perseus, and here the early life of Hercules (*Tirynthius*) was spent. About 468 B.C. the city was destroyed by the Argives, but the ruined walls of the citadel remained the wonder of later ages. The Cyclopean walls of Tiryns and of the neighbouring city of Mycenæ are the grandest in Greece. The citadel was built on an oval-shaped rock, 330 yards long by 112 at its widest, fringed by a wall, 30 to 40 feet thick, and about 50 feet high (from the outside base), composed of blocks, bedded in clay, 10 feet long by 3½ wide. The area of the city was divided into three parts at successive levels, and one of these was completely excavated by Schliemann in 1884–85, thus exposing the complete plan of a Greek palace of the 11th or 10th century B.C. See Dr Schliemann's *Tiryns* (Lond. 1886).

Tischendorf, Lobegott Friedrich Konstantin von, a very eminent biblical scholar, was born at Lengenfeld in Saxony on January 18, 1815, and studied theology and philology at Leipzig, where in 1839 he became a university lecturer.

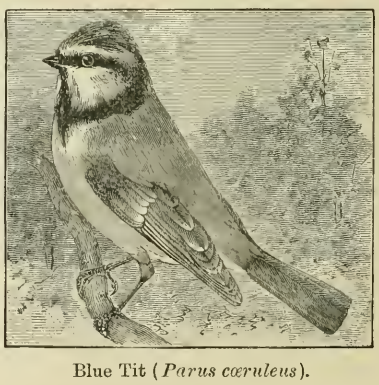
His labours in search of the best and most ancient MSS. of the New Testament, in which he was liberally assisted by the Saxon and Russian governments, were exceedingly valuable, especially those in 1844, 1853, and 1859, which resulted in the discovery of the Sinaitic Codex (see CODEX) at the monastery on Mount Sinai; those journeys he described in *Reise in den Orient* (2 vols. 1846; Eng. trans. 1847) and *Aus dem Heiligen Lande* (1862). Among the most important of his numerous works are the editions of the Sinaitic (1862; in fac-simile in 1863) and many other MSS. of the New Testament; the *Eighth Critical Edition of the New Testament* (1864–72), and several other editions of the New Testament text; an edition of the Septuagint; and the *Monumenta Sacra Inedita* (1846–71). The pamphlet *When were our Gospels Written?* defending the genuineness and authenticity of the four gospels, was translated into English in 1866. After being an extra-ordinary and ordinary professor at Leipzig from 1845, he became professor of Theology and of Biblical Palæography in 1859, a chair in the latter subject having been instituted for him. He was created a Count of the Russian empire, an LL.D. of Cambridge, a D.C.L. of Oxford, &c. He died on December 1, 1874. There is a sketch of his life by Volbeding (1862).

Tissandier, GASTON. See BALLOON.

Tissues, aggregates of cells which have certain characters in common. They may be classified in various ways according as attention is directed to their structural, functional, or developmental characters. Thus, in an animal, 'cellular tissues,' in which the unit elements retain their distinctness, may be distinguished from those of muscle and nerve, in which there is usually much modification and integration of the component cells. Or, in plants, 'cellular tissues' may be distinguished from 'vascular tissues,' in which the component cells are fused to form vessels. In these distinctions only structural characters are considered. Again, we may distinguish in an animal nervous tissues, muscular tissues, glandular tissues, skeletal tissues, and so on, the classification here depending on the function. In the same way the tissues of a plant may be distinguished as absorptive, assimilative, conductive, glandular, skeletal, protective, and so on. In short, the physiological conception of a tissue is that of an aggregate of cells in which by division of labour within the body there has come to be a predominance of one function. Or, if we consider the origin of the several tissues from the different layers of the embryo, we distinguish the ectodermic or epiblastic, the mesodermic or mesoblastic, the endodermic or hypoblastic tissues of animals, and similarly in higher plants we distinguish those which arise from the dermatogen, periblem, and plerome of the embryo or growing-point. The commonest classification of animal tissues is perhaps that which distinguishes four sets—(*a*) epithelial, including covering and lining layers of cells, and their secretory or other modifications; (*b*) muscular; (*c*) nervous; (*d*) connective tissues; but the last includes a great variety—e.g. bone, cartilage, ligaments, and enswathing membranes. One of the most convenient classifications of vegetable tissue is that which distinguishes (*a*) cellular tissues—epidermis, parenchyma, prosenchyma; (*b*) vascular tissues—wood and bast vessels, and laticiferous vessels.

See the articles BARK, BAST, BICHAT, BONE, BRAIN, CELL, CIRCULATION, DIGESTION, EMBRYOLOGY, EPIDERMIS, EPITHELIUM, HORN, KIDNEYS, LEAF, MUSCLE, NERVOUS SYSTEM, PHYSIOLOGY, REPRODUCTION, RESPIRATION, SKIN, VEGETABLE PHYSIOLOGY, WOOD, &c.

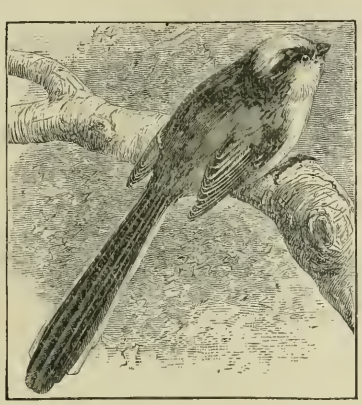
Tit, or TITMOUSE, a name given to several genera of Passerine birds in the family Paridæ. The typical tits are small birds, of which there are over sixty species, widely distributed throughout Europe, Asia, Africa, and North America. They are more numerous in cold and temperate than in tropical regions, those which are found within the tropics being mostly inhabitants of elevated mountainous districts. The bill is small, short, somewhat conical, the tip entire, the base beset with hairs, and the nostrils generally concealed by feathers. The wings are not very long; the tail is rounded or even; the legs rather short, slender, scaled in front, the inner toe shortest, the claws long and curved. The plumage is soft, lax, and fluffy, often gay. The popular name Titmouse is derived from Anglo-Saxon *mâse,* a small bird (*tit,* 'small'). The tits are bold sprightly birds, extremely active, flitting from branch to branch, running rapidly along branches in quest of insects, and often clinging back-downwards to the under side of branches. They feed not only on insects but on grain and seeds, occasionally eat carrion, and sometimes kill young and sickly birds by strokes of their bill. They are very pugnacious, and the female tit shows great courage in defence of her nest, often continuing to sit when the nest is approached, and vigorously assailing the intruding hand with her bill. In winter many of the species gather into small flocks, and approach houses and villages, competing with sparrows and chaffinches for a share of the food of domestic poultry. Most of the tits lay at least six eggs, some of them twelve or more, and even in temperate countries they often produce two broods in a year. They generally build in holes in trees,



Blue Tit (*Parus cæruleus*).

&c. The young are fed chiefly on caterpillars. A pair of blue tits have been observed to carry a caterpillar to their nest, on an average, every two minutes during the day, so that these birds must be extremely useful in preventing the multiplication of noxious insects. Six species are found in Britain, but one of them, the Crested Tit (*Parus cristatus*), is very local, being almost entirely confined to a few old pine-forests in Scotland. The Great Tit (*P. major*) is the largest European species. It is common in almost all parts of Europe. It is not quite six inches long; the head and throat are black; the cheeks are white; the breast and sides yellowish; the wings and tail grayish. Its usual note is a kind of chatter, but it sometimes imitates the notes of other birds. The Blue Tit (*P. cæruleus*) and the Cole Tit (*P. ater*) are very common in Britain. The blue tit is perhaps the most pert and audacious of all the British species. It very generally receives the familiar name of *Tomtit.* The upper part of the head is light blue, and a bluish tinge prevails in the plumage. The Long-tailed Tit (*Acredula caudata*), common in Britain, has the tail about as long as

the body. Its crown is white, contrasting beautifully with the deep black of the back; the tail is also black, with white edges. The nest of this bird is a beautiful structure, of moss and wool externally covered with lichens, and profusely lined with feathers, nearly oval, with a small hole in the upper part of one side. Still more interesting is the nest of the Penduline Tit (*Aegithalus pendulinus*) of the south of Europe, which in form resembles a flask, and is generally suspended at the end of a flexible twig, in a situation near to or overhanging water. It is nicely woven of fibres of bark



Long-tailed Tit (*Acredula caudata*).

and the down of willow or poplar catkins, and the opening is in the side. The Chickadee or Black-cap Tit (*P. atricapillus*) is very common in North America. The Tufted Tit (*P. bicolor*) is the largest American species. British specimens of the Cole and Long-tailed Tits differ somewhat from continental examples, and are sometimes held to be specifically distinct. The so-called Bearded Tit (*Panurus biarmicus*) belongs to a distinct family (Panuridæ). It frequents reed and osier beds, and the male is tawny, with gray head and black moustaches, which ornaments are absent in the female. It is rare in England. See Howard Saunders, *Illustrated Manual of British Birds* (Lond. 1889); Gould, *Birds of Great Britain, Birds of Asia*.

Titania. See MAB, OBERON.

Titanium (sym. Ti, eq. 48) is a comparatively rare metal, which, according to the method by which it is procured, occurs as a gray, heavy, iron-like powder, which burns with brilliant scintillations in the air, forming titanium dioxide and nitride. It decomposes water at the boiling-point and is soluble in hydrochloric acid. It never occurs native, but is present as the dioxide in the minerals Rutile (q.v.), brookite, and anastase. Commercially it is of little value, and its chief outstanding property is the readiness with which it combines with nitrogen under the influence of heat.—*Titanite*, or sphene, is a soft mineral, green, yellow, or yellowish green, has strong refractive and dispersive power on light, and has a brilliant play of diamond-like colour-effects. It is often present in Syenite (q.v.).

Titans, in Greek Mythology, were the sons and daughters of Uranus (Heaven) and Gæa (Earth), amongst whom were Kronos (see SATURN), Oceanus, Rhea, &c. Instigated by their mother, the Titans, headed by Kronos, rose against their father, emasculated and deposed him, and liberated their brothers, the Hecatoncheires (Hundred-handed) and the Cyclopes (q.v.), from Tartarus. Kronos, being made king, married his sister Rhea. Zeus, the son of Kronos and Rhea, waged against his father and the other Titans a ten years' war, in which the Titans were defeated and hurled into Tartarus. During the war Zeus and his allies occupied Mount Olympus in Thessaly, his opponents being encamped on Mount Othrys. The name of Titans is also given to the descendants of the Titans, such as Prometheus, Hecate, Helios, Selene, &c. See GIANTS, ZEUS.

Tithe (A.S. *teotha*; Lat. *decima*, sc. *pars*) means etymologically a tenth, historically a tenth part of the titheable produce of the land paid to the clergy. The payment of tithe to the clergy originated in the recognition of a moral and religious duty. The discharge of this acknowledged obligation acquired the force of custom, then received the sanction of ecclesiastical law, and finally passed into the national jurisprudence of England and other Christian countries.

The first recorded instance of the payment of tithe is the offering of Abraham to Melchisedec (Gen. xiv. 20); the second precedent is the vow of Jacob at Bethel (Gen. xxviii. 22). The consecration of a fractional portion of the produce of the land to the uses of the ministers of religion formed part of the Mosaic law. The tribe of Levi were maintained from this source, not having lands assigned to them like the other tribes. Neither patriarchal usage, nor precedents of Mosaic law, nor the Levitical economy were binding on Christians; but they doubtless suggested to the clergy the precept, and to the people the practice, of paying tithes to the ministers of religion. The system is not specially enjoined in the New Testament, and no claim to tithes is urged by the Christian clergy as representatives of the Levitical priesthood. In the enthusiastic bounty of early Christianity voluntary offerings sufficed. Some evidence does exist in the ante-Nicene Fathers that tithes were held to be due under the gospel as well as under the Mosaic law; on the other hand, Selden is possibly right in maintaining that the custom of paying tithe cannot be traced before the 4th century. Whether this be so or not is immaterial. At the end of the 4th century the evidence is overwhelming (Hilary, Ambrose, Chrysostom, Jerome, Augustine) that the moral and religious duty of paying tithes was recognised, and had acquired the force of custom. As a moral and religious custom the payment of tithes was enjoined by the public acts of councils and churches, and enforced by moral and religious sanctions (e.g. Councils of Tours, 567; Mâcon, 589; Rouen, 650; &c.). The last stage was reached when the state added the civil sanction to the ecclesiastical sanction. In doing so the state recognised the already accepted customary duty, and the corresponding customary rights. It created no new burden; it appropriated no part of what had hitherto been a public fund or public revenue. On the Continent the attachment of legal sanctions to ecclesiastical customs dates from Charlemagne's legislation in 779 and 787. Henceforward tithes were enforced by temporal penalties.

Before Augustine landed in Kent (597), the custom of paying tithes had been enjoined by the public acts of continental councils. As a duty the payment of tithes was preached by the first missionaries; as a custom it was speedily established by their successors. But it was not till 785 that the custom was enjoined by ecclesiastical legislation. In 785 two Italian bishops were sent by Pope Adrian I. to recommend twenty-nine Latin injunctions to the observance of the Anglo-Saxon Church. Among them was one injunction which urged the payment of tithes as a means of securing to the payer the blessing of God. Thus the customary discharge of a recognised religious

duty was for the first time enforced in England by the public act of an ecclesiastical council.

This ecclesiastical injunction was subsequently confirmed and extended by royal orders in episcopal councils, in national synods, and in proclamations of peace. But it was not till 970 that the state recognised the customary duty and its corresponding customary right by adding the civil to the ecclesiastical sanction. It is now agreed that the so-called grant of King Offa is an idle story relating to Peter's Pence, and that the so-called grant of King Ethelwulf rests on a misconstruction of a document which has no reference to tithes. No law, no charter, no authentic public document exists by which the state professes to confer the right to tithes upon the church. But the laws of King Edgar (970) attached a legal punishment to neglect of the customary and religious duty of paying tithes, and provided means of enforcing the corresponding customary right by temporal penalties. These laws were subsequently confirmed by successive sovereigns, though it was not till after the Conquest that the payment became general. The process by which tithes grew from a moral into a legal duty does not explain their special allocation as the local endowments of parishes. In their appropriation as part of the parochial system three stages may be distinguished: (1) before 970; (2) from 970 to the end of the 12th century; (3) from 1200 onwards.

(1) *Before 970.*—During the first three centuries of the Anglo-Saxon Church there was in each diocese one common treasury, into which were paid the tithes and other offerings of the faithful. As to the distribution of these funds by the bishop, different usages prevailed in different parts of western Christendom. In the Roman dioceses the customary division was fourfold: (1) the clergy, (2) the poor, (3) the fabrics of churches, (4) the bishop. In some of the French and Spanish dioceses the division was threefold, the bishop being omitted. What usage prevailed in the Anglo-Saxon Church is unknown. No division, quadripartite or tripartite, was ever enjoined by law or canon in England.

(2) *From 970 to end of 12th century.*—In this transition period the parochial system grew up, and local appropriations were made to particular churches out of the common fund. Edgar's legislation (970) shows that the parochial system was already growing. His legislation points to the fact that landowners were building churches on their estates for their own and their tenants' benefit, and were endowing them with some portion of the tithe, which they otherwise paid to the diocesan treasury or to the nearest monastic or conventual establishment. It distinguishes three kinds of churches: (1) the mother-church, generally monastic or conventual; (2) churches with burial-grounds attached, in private patronage on the estates of private landowners; (3) churches similarly situated, but without burial-grounds. It recognises the general presumption in favour of paying to the mother-church the tithe of the district which it served, but if there was a church of the second class within the district it was entitled to a portion of the local tithe. In these churches we have the original type of modern parish churches. By degrees they multiplied, and, as they were built, bishops insisted upon their endowment with a portion of the local tithe as a condition of consecration. Districts were attached to them, which were generally conterminous with the estate of the founder, and which became the parish. The same process was going on not only on lay estates, but on the estates of bishops and other ecclesiastical corporations. Thus the parochial system gradually became uniform, and by a series of acts, which in each case were distinct and voluntary on the part of the landowner, the local tithes became appropriated without any legislative enactment to parish churches. No general law, no legislative enactment, effected the endowment; but by express particular grants, of which, in the shape of consecration deeds, several remain to the present day, each church was separately endowed.

(3) *From 1200 onwards.*—This date makes a dividing line in the growth of the parochial system, because by that time the system was almost universal, and because the legal presumption had arisen that, in the absence of proof to the contrary, the tithes of all titheable produce within the parish belonged of common right to the rector. The decrees of the Lateran Council, 1179–80, made two important steps, according to Selden, towards the growth of the system. Up to that date landowners had been free to pay the tithes as they pleased: they might, and did, 'appropriate' them to churches, monasteries, or capitular bodies; they might 'appropriate' them to themselves or other laymen; they might, and did, sell them to the church for money or other valuable consideration. Out of this power had arisen all the endowments of parish churches and monasteries with tithes which took place between the 10th and 13th centuries. From 1180 onwards no new titles of this kind could be created without the consent of the bishop, and the loss of the power of appropriation, together with the legal presumption in favour of the rector's title, provided for the expansion of the system on stereotyped lines. The other change in 1180 was this. Parish priests were originally nominated and invested by lay patrons. Bishops did not institute; hence when vacancies occurred in manorial parish churches patrons could not be compelled to fill them up. The council decreed the necessity of episcopal institution, and established the right of the bishop to supply vacancies after the lapse of a certain delay. The almost universal establishment of the parochial system, the legal presumption in favour of the rector, the episcopal institution, and the bishop's right to supply vacancies completed the organisation of parishes and provided for present and future appropriations of local tithes to parish churches.

Rectories together with tithes might be 'appropriated' to monastic or nonparochial corporations. The appropriators performed their duties by vicars. At the dissolution of the monasteries the rectorial tithes which had belonged to the dissolved communities passed to the crown, and were from time to time granted out to subjects, who became lay rectors or 'impropriators' as they were called to distinguish them from the original 'appropriators,' who must of necessity have been spiritual. The Tithe Commutation Act of 1836 provided for the commutation of tithes in England and Wales into a money payment or rent-charge. Though the annual payment varies with the septennial average price of corn, it is fixed in the sense that the amount payable in each year is calculated upon a rent-charge or fixed valuation. The effect of this act is to render the old distinctions between great and small tithes, prædial, mixed, and general tithes, and between the various modes of payment by 'moduses' matters of antiquarian knowledge. The value of the tithes commuted in 1836 to tithe rent-charge was at par value £4,053,985, 6s. 8½d. Of this sum £962,289, 15s. 7¼d. is payable to lay impropriators, leaving £3,091,695, 11s. 1¼d. for ecclesiastical owners. Of this latter sum £678,987, 1s. 1¾d. is payable to Ecclesiastical Commissioners. The remainder, £2,412,708, 9s. 11½d., is payable to parochial incumbents. At the present values this sum is worth about in round numbers £1,800,000. To this sum may be added about £8000 for *extra-*

ordinary tithe in Kent and Cornwall. In Ireland the settlement was effected by a general commutation of tithe into a money rent-charge, regulated by a valuation of the tithes (one-fourth being deducted for the cost of collection), and payable by the proprietors, who should receive it from the occupiers of the land. By the Irish Church Act, 1869, this rent-charge became vested in the commissioners of church temporalities, with power to sell such rent-charge to the owner of the land charged therewith at twenty-two and a half years' purchase. Power is also given to such purchaser to pay by instalments for fifty-two years, at the rate of 4½ per cent. on the purchase-money, deducting the estimated charge for poor-rate; the rent-charge being extinguished at the expiration of the fifty-two years. The Extraordinary Tithe Act, 1886, frees lands not at present cultivated as hop-ground, orchard, fruit plantation, or market-garden, from liability to the separate tithe which, under the Act of 1836, could be claimed as extraordinary. It also provides for the redemption of the extraordinary tithe in existence upon the land actually under cultivation. The Tithe Rent Charge Recovery Act of 1891 has not materially affected the principle of the Act of 1836. But instead of the old remedy of distress by the tithe-owner, it substitutes a process through the county court; instead of permitting the tenant to be the conduit-pipe of the landowner's payment, it makes the landowner alone liable; instead of the corn-averages absolutely determining the amount of tithe rent-charge which is payable, provision is made in certain cases for the reduction or the suspension of payment.

In 1891 a Royal Commission was appointed to consider the redemption of tithe rent-charges. The Commission has reported *inter alia* in favour of the compulsory redemption of tithes up to the value of 40s., of the abolition of the existing *minimum* of twenty-five years' purchase, of the principle of allowing the parties to make their own bargains subject to the approval of the Board of Agriculture. See TEINDS, ADVOWSON; and works on the history of tithes by Easterby, Jones, Clarke, Lord Selborne (1888), and on the tithe acts by Whalley (1838; new ed. 1883), Bolton (1886), Chambers (1891), Studd (1891), and Thring (1891).

Tithing. See HUNDRED. The tithing man in England was a kind of constable. In New England he was a town-officer, yearly elected to exercise a moral supervision, or to enforce attendance at public worship.

Tithonus, son of Laomedon, brother of Priam, and spouse of Eos, the goddess of Morn. The story is that Eos, in asking immortality for her spouse, forgot to ask at the same time eternal youth, so that in his old age he became completely shrunk and decrepit, whereby his 'cruel immortality' was rendered a burden to him.

Titian. The life of Titian is the longest in the biographies of artists, and it was also one of the most productive, as he worked quickly and energetically, enjoyed almost perfectly regular health, and produced regularly, except when his labours were occasionally interrupted by festivities or by travel. The consequence is that the biography of Titian is one of the most difficult to write laconically. If too much compressed, it would become a mere list of dates. In this brief notice there must be many omissions. It will be divided into three parts, treating separately of the artist's life, his patrons, and his works.

Copyright 1892 in U.S. by J. B. Lippincott Company.

The Anglicised form of the name is obtained by dropping the final *o* from Titiano, which was the artist's most common signature, though he sometimes wrote Tiziano, occasionally Ticiano, and rarely Tician. The English form, therefore, is nearer to the most frequent signature than the French *Titien*. The modern Italians have preferred Tiziano. The painter's contemporaries gave various forms to his name from uncertainty or carelessness, as for instance Tuciano.

Titiano Vecellio was descended from a respectable but not wealthy family. The surname Vecellio or Vecelli appears to have been originally a Christian name, Guccello, but at the time of the painter's birth it was fixed as a surname, and Tiziano afterwards became common in the family. The date of the painter's birth is not quite positively fixed, except that the year is indicated by his own statement on August 1, 1571, that he was then an old man of ninety-five, so he cannot have been born later than 1477. His birthplace was close to the castle of Cadore, in a very mountainous region, and his continued attachment to the country of his birth is proved by his frequent visits to it, and by his numerous sketches of its scenery. Titian's father, Gregorio Vecellio, was a brave officer who filled various important civil functions in his native place, and was greatly respected both for wisdom and valour, but he was a poor gentleman. Gregorio sent his little son to Venice at the age of ten, to the house of an uncle, who saw that he had a turn for art, and sent him to Zuccato, a mosaicist, and afterwards to Gentile Bellini. That painter disapproved of his pupil's rapidity, so the boy (who seems to have enjoyed a good deal of independence for his years) first went to Giovanni Bellini, and afterwards to Giorgione. This is evidence that as a quick and intelligent little boy and an observant youth Titian actually saw the transition from comparatively primitive to advanced art at the moment when it took place, and that he adopted without hesitation for himself what were then the most modern and advanced principles.

The rapidity with which Titian absorbed all that was known at Venice about the art of painting is proved by the simple fact that he produced a masterpiece at twenty-three, and very soon had plenty of employment, both in fresco on public edifices and in oil. In 1511 he was painting fresco at Padua, and in 1516 he made his first visit to Ferrara. There are no events in his life outside of his work till 1524, when he had a fever that prostrated him and threatened to become chronic. The date of Titian's marriage is unknown, but the birth of his eldest son, Pomponio, is believed to have occurred in 1525. All we know is that he had a wife whose name was Cecilia. He contrived, by influence, to obtain ecclesiastical preferment for Pomponio though a mere child, the work being done by a curate. Afterwards he had two other children, Orazio and Lavinia. Pomponio turned out badly; Orazio, a painter, survived Titian a few months; and Lavinia married. Titian's wife died in 1530, to his intense grief. In the year following he went to live in the fields to the north-east of Venice, where he had a large house with a fine garden, probably going down to the water's edge, and a view of the lagoon. The year 1532 is of importance, as Titian became acquainted with the Emperor Charles V., who made him a count palatine, with other titles, a rank which empowered him to appoint notaries and judges, and legitimise the illegitimate offspring of persons beneath baronial rank. He was also made a Knight of the Golden Spur, with insignia, and the *entrée* at court, and his children were all ennobled. In 1536 he went with the Duke of Mantua to greet Charles V. at Asti. In 1543 Titian met Pope Paul III. and Charles V. at Busseto, where he was the guest of Cardinal Farnese. Two years afterwards

he visited Rome, where he was welcomed by Paul III., and in 1546 he returned to Venice. His vigour at the age of seventy was proved by a winter journey across the Alps to Augsburg, where he joined the court of Charles V. He returned to the court at Augsburg in 1550, and probably followed it to Innsbruck in 1551. In 1554 the troubles with his son Pomponio reached a climax, and Titian asked to substitute a nephew for him in the sinecure canonry of Medole. An interesting example of the protection of copyright is a patent granted in 1566 by the Council of Ten, recognising Titian's copyright in prints from his own works. The later part of his life was chiefly occupied in working at Venice for Philip II. of Spain. He still retained energy for work, as is proved by his undertaking in 1576 a large picture for the Franciscans. In the same year he died of the plague, at the age of ninety-nine, and was buried with much public honour, and by daylight, in the chapel of the Crucified Saviour at Frari, a striking exception to the usual practice with regard to persons dead of the plague. Titian's son, Orazio, died of the same disease a few months later in a hospital.

Titian was extremely fortunate in his patrons. The Venetian government acted generously towards him, and on the whole with great indulgence, considering his negligence and delays. He had a great love of pensions, privileges, and sinecures, and was always trying to get them for himself or his relations. He was perpetually begging, and his access to great people gave him excellent opportunities. He was patronised by people of the highest rank, including Doges of Venice, reigning Dukes of Ferrara and Mantua, several cardinals, princes, kings, Pope Paul III., and the great Emperor Charles V. All these personages treated Titian with the greatest kindness and consideration, but although a gentleman in his manners, and a courtier in his correspondence, he sometimes, by negligence, tested their patience very severely. His friendship with Charles V. was intimate, and lasted, in spite of distance, until the emperor's death. Titian's character was not comparable in dignity to that of Michaelangelo; it was the nature of a polished self-seeking courtier; but he was an affectionate husband and father, an amiable and sociable companion, and a warm friend. There is no evidence that Titian had much learning—his art would not leave time for that; but he had derived a rare and valuable culture from his immense experience of the world.

Titian's works are so numerous that it is impossible to catalogue them here. He was much in request as portrait-painter, and painted most of the great people he knew, several of them repeatedly. His religious pictures are numerous and magnificent, some of them on a large scale, and like other artists of the Renaissance he frequently chose mythological subjects. Some of his finest works are poetical or allegorical. The supreme rank amongst painters is sometimes assigned to Raphael and sometimes to Titian. Raphael's claim to it is in the extreme grace and refinement of his mental conceptions and in the beauty of his style as a draughtsman; Titian's claim is founded more essentially on the pictorial qualities, and especially on the technical excellence of his painting, which combines in a most extraordinary degree the richest surface with the most magnificent colour. These technical qualities were accompanied by much grandeur of conception and nobility of style. The following is a chronological list of some of Titian's most important works.

'Sacred and Profane Love' (the title 'Artless and Sated Love' has been proposed by Messrs Crowe and Cavalcaselle), about 1500; the 'Pesaro Altarpiece,' at Antwerp, about 1503; 'Doge Marcello,' at the Vatican, 1508; 'Christ of the Tribute-money,' Dresden, 1508; 'The Three Ages,' Ellesmere Collection, 1518; 'Noli Me Tangere,' National Gallery, 1518; 'Bacchus and Ariadne,' National Gallery, 1520; 'Titian and his Mistress' (so called), 1513; 'Altarpiece of St Peter Martyr,' 1530, destroyed by fire at Venice in 1867; 'The Rest in Egypt,' Louvre, 1530; 'A Summer Storm,' Buckingham Palace, 1534; 'The Battle of Cadore,' for the council-chamber at Venice, 1537, destroyed by fire in 1577; 'The Farnese Family Picture,' 1545; 'The Danae of Naples,' 1545; 'The Farnese Venus and Adonis,' 1547; portraits of Philip of Spain, 1550; 'Venus and Adonis,' National Gallery, 1554; 'Martyrdom of St Lawrence,' Gesuiti, Venice, 1558; 'Jupiter and Antiope,' Louvre, 1561; a second 'Peter Martyr,' 1567.

Titian is well but not extensively represented in the National Gallery by five pictures, and in the Louvre by twenty-two. Other public collections are rich in Titians. At Dresden there are twelve, at Vienna thirty, and at Madrid forty in the Museum, with many others at the Escurial. His drawings are interesting, especially his numerous pen-sketches, executed in a bold and simple but very expressive style of his own. They afford strong evidence that his lines, which were intended to be vertical, inclined very much to the right. In all his finished works he corrected this tendency with the plummet.

Many biographies of Titian have been written, from that by Vasari to the French one by Charles Blanc; but although the materials were in reality abundant, they were scattered till Crowe and Cavalcaselle brought them together for their invaluable work, the *Life and Times of Titian* (London: Murray, 2d ed. 1881). Between Vasari and Crowe we have a biography by Ridolfi, condensed by Sir A. Hume in an English edition, published in 1829. The most important step towards a life of Titian was taken by Taddeo Jacobi early in the 19th century. As a descendant of the Vecelli family he was interested in his ancestors, and collected materials for their history, but not having a literary turn he transferred them to Stefano Ticozzi, who published his book in 1817. That of Northcote is founded upon it.

Titicaca. Lake. See Peru, Bolivia.

Titiens, or Tietjens, Teresa, one of the greatest of modern operatic singers. She was born at Hamburg, of Hungarian parents, 18th July 1831, and made her début at Altona in the character of Lucrezia Borgia in 1849, taking at once a very high position on the lyric stage; at Frankfort and Vienna she was even more warmly received; and her first appearance in London in 1858 was quite a triumph. Among her most famous impersonations were Norma, Semiramide, Fidelio, Margarita, and Ortrud (in *Lohengrin*). She visited America in 1875. The great volume and purity of her voice, and her energetic but dignified acting, combined to make her an unrivalled representative of strong dramatic parts. She was almost equally admirable in oratorio: Sir Julius Benedict wrote *St Cecilia* and other works specially for her. She sang for the last time in public in May 1877 in *Il Trovatore*, and died 3d October of the same year.

Titlark. See Pipit.

Title-deeds are the evidences of ownership of real property. Each owner is supposed to be in possession of his own, either by himself or his solicitors; and the ownership of the title-deeds passes along with that of the lands themselves. See Registration.

Titles, designations to which certain persons are legally entitled, in consequence of possessing particular dignities or offices; see Address (Forms of), Precedence, Majesty, Royal Family, Duke, Marquis, &c.; also Courtesy Titles.

Though most European countries have their dukes, marquises, counts, viscounts, and barons, these often differ considerably in rank from the seemingly corresponding titles in Britain, and the English rules and practices regarding title are not applicable abroad. The complicated system of titles by law, and still more by courtesy, which prevails in England is a source of endless perplexity to such foreigners as endeavour to make themselves acquainted with British usages. For a title to Orders, see Vol. VII. p. 630; and for the subject of titles generally, see Edward Solly's *Index of Hereditary Titles of Honour* (Index Soc. 1879).

Titmouse. See Tit.

Titular, one who enjoys the bare title of an office, without the actual possession of that office. Thus, the English kings styled themselves kings of France from the time of Henry IV. down to 1800. In English Ecclesiastical Law a titular is a person invested with a title in virtue of which he holds a benefice, whether he performs its duties or not. In Scotland the term was used by laymen invested at the Reformation with church lands; see Teinds. Leo XIII. altered to 'titular bishops' the old title of bishops *in partibus* (see Vol. VI. p. 149).

Titus, the Roman prænomen but the usual name for the eleventh of the twelve Cæsars, Titus Flavius Sabinus Vespasianus, the eldest son of Vespasian and Flavia Domitilla, born at Rome, 30th December 40 A.D. He was brought up at the court of Nero along with Britannicus, and early served with credit as tribune in Germany and Britain, and in Judæa under his father. On Vespasian's elevation to the throne Titus was left to prosecute the Jewish war, which he brought to a close by the capture of Jerusalem after a long siege (70). Both father and son enjoyed a joint triumph in 71. About this time Titus received the title of Cæsar, and took a share in the work of government. He gave himself up to pleasure, and his attachment to Berenice, the daughter of Herod Agrippa I., grievously offended the Romans. But no sooner had Titus assumed the weight of undivided power (79) than his whole character became changed. The very first act of his reign was to put a stop to all prosecutions for *læsa majestas*, and to decree heavy punishments against informers. He assumed the office of Pontifex Maximus in order to keep his hands free from blood. He completed the Colosseum and built the baths which bear his name, and lavished his beneficence upon the sufferers from the great eruption of Vesuvius, which overwhelmed Herculaneum and Pompeii (79), and the great three days' fire at Rome, followed by pestilence the year after. Titus was now the idol of his subjects, the 'love and delight of mankind.' He loved to give, and the characteristic story is told that one night he exclaimed 'I have lost a day' when he remembered that he had given nothing away that day. But unhappily he died suddenly at his patrimonial villa in the Sabine country (September 13, 81), not without the suspicion that he had been poisoned by his younger brother Domitian.

Titus, one of the companions of the apostle Paul, is (apart from the epistle with which his name is associated) mentioned only in 2 Cor. and Gal. He was a Greek, and remained uncircumcised after his conversion. He accompanied the apostle from Antioch to Jerusalem, where the latter took part in the church council held to discuss the Christian privileges of Gentiles. He was thrice sent to Corinth: on the first occasion, from Ephesus, as bearer of a no longer extant epistle (2 Cor. ii. 3, 4; vii. 8, 12); afterwards, from Macedonia, with the second canonical epistle; and a third time to promote the collection in Corinth for the poor Christians of Judæa. According to Tit. i. 5 he accompanied the apostle to Crete, and was left by him there. Ecclesiastical tradition makes Titus 'bishop' of Crete. For the canonical epistle to Titus, and works thereon, see Timothy (Epistles to).

Titusville, a city of Pennsylvania, on Oil Creek, 120 miles by rail SSW. of Buffalo. It contains oil wells and refineries, and, though it possesses also sawmills, ironworks, &c., its prosperity is mainly dependent on the oil-trade. In June 1892 it suffered much from a great flood. Pop. (1859) 300; (1880) 9046; (1890) 8073.

Tiumen, a town and important commercial centre of western Siberia, 90 miles SW. of Tobolsk, on the Tura, an affluent of the Tobol, and so of the Irtish and Obi. Connected by rail with Perm and the Russian system, it is on several important trade routes both by land and water; and large quantities of leather, carpets, soap, candles, and pottery are manufactured and exported throughout Siberia, the Ural countries, the Kirghiz Steppes, Khokand, Bokhara, and China. It has a large scientific and technical school, and there is a great fair in January. Tiumen contains an important exile forwarding prison (see books cited at Siberia). Pop. (1900) 25,500.

Tiverton, a municipal borough of Devonshire, 14½ miles N. by E. of Exeter, stands pleasantly on an eminence between the confluent Exe and Loman, and got the name *Twy-ford-ton* from two fords upon those two rivers. Little save the gateway remains of the castle of the Earls of Devon, built in 1106, and dismantled after its capture by Fairfax in 1645. St Peter's, a Perpendicular church of the 15th century, was mostly rebuilt in 1855; and other edifices are the town-hall (1864), late Venetian in style, with a tower 80 feet high, the market-house (1830), the infirmary (1852), the Greenway almshouses (1517), Waldron's almshouses (1579), and the grammar-school (1604), which was founded by Peter Blundell (1520–1601), and has an endowment of £1100 a year. Among its scholars have been Bishops Bull, Hayter, Conybeare, and Temple, A. Hayward, R. D. Blackmore, and his hero, John Ridd. New school buildings in the Tudor style were erected in 1880 at a cost of £20,000. Tiverton was a great seat of the woollen trade from 1353 till 1700 and afterwards, but lace-making is now its staple industry, the lace-factory, employing 1500 workpeople, having been established in 1816 by Mr John Heathcoat (1783–1861), inventor of the bobbin-net frame. Cosway, the painter, and Mrs Cowley, dramatist, were natives; whilst Lord Palmerston for thirty years (1835–65) represented Tiverton, which was chartered by James I., but lost its two members in 1885. Pop. (1851) 11,144; (1871) 10,025; (1891) 10,892. See works by M. Dunsford (1790), W. Harding (2 vols. 1844–47), and F. J. Snell (1893).

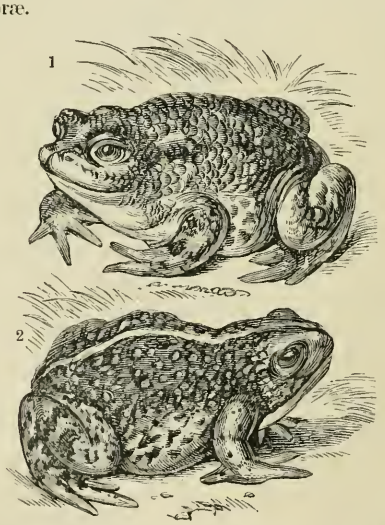
Tivoli, a town of Italy, 18 miles E. of Rome by rail and steam-tramway, on the slope of the Sabine hills and the river Teverone (ancient *Anio*, q.v.). Here works for the electric lighting of Rome were inaugurated in 1892. Under its ancient name of *Tibur*, it was the favourite summer-resort of the wealthy Romans; and it retains many monuments of antiquity. In a commanding position above the falls of the Anio rises the so-called Sibyl's temple, circular, and in good preservation; the church of San Giorgio is an ancient temple; there are extensive remains of the Emperor Hadrian's magnificent villa, the villa of Mæcenas, mausoleums, aqueducts, baths, &c. Near Tivoli is the famous Villa d'Este, dating from 1551. The name of Tivoli is often used elsewhere (as in Germany) as a synonym for places of entertain-

ment, beer-gardens, &c. Pop. 9370. Tibur was a town before the building of Rome, and belonged to the Latin confederation. At a later date Mæcenas, Scipio, Æmilianus, the famous Marius, Metellus Numidicus, and Munatius Plancus had their Tiburtine villas. Horace preferred Tibur to all other places of resort, and had a country-house in the neighbourhood.

Tlaxcala, the smallest state of Mexico, on the plateau of Anahuac, nearly surrounded by Puebla, and touching Mexico state on the west. In Aztec days Tlaxcala was the seat of an independent republic, which survived for a time under the protection of the Spaniards. Area, 1506 sq. m.; pop. (1890) 138,478. The capital, Tlaxcala, stands 7300 feet above the sea, and has some manufactures of woollens. Pop. 4300.

Tlemcen', a town of Algeria, 80 miles SW. of Oran, stands on a rock in an undulating country, with a delightful climate, and surrounded by olive-plantations and vineyards. Pop. (1891) 19,832, of whom 2572 are French by birth or naturalisation, and nearly 5000 Jews.

Toad (*Bufo*), a genus of amphibians, typical of the family Bufonidæ, represented in Britain by two species—the Common Toad (*Bufo vulgaris*) and the Natterjack (*Bufo calamita*). Toads are distinguished from frogs by the absence of teeth, by the roughness of the skin, by peculiarities in the breastbone, by the shorter hind-legs, and by the dilatation of the tranverse processes of the sacral vertebræ.



1. Common Toad (*Bufo vulgaris*); 2. Natterjack (*Bufo calamita*).

The common toad is a shy, nocturnal animal, hiding during the day in dark, damp places, crawling about at night in search of insects, grubs, slugs, worms, and the like. Its appearance is familiar—a dirty brownish-gray colour, a warty skin, a flat head, swollen parotid glands above the ears, bright jewel-like eyes with a transverse pupil, slightly webbed toes. They are heavier and clumsier than frogs, and cannot leap nearly so far. Hardy and tenacious of life, they often live for many (even forty) years, and can endure prolonged fastings. According to Buckland's experiments, a toad cannot live for two years without food and air; still, though tales of toads disentombed from blocks of rock must be discredited, there is no doubt that they can survive for a long time in very disadvantageous conditions. During winter they hibernate in the mud or in holes. In spring they pair, and the females lay in the water-pools their numerous ova in gelatinous strings 3 or 4 feet in length. The tadpoles are smaller and darker than those of frogs, and do not accomplish their transformation into terrestrial toads until autumn. Though toads cannot spit poison, the secretion of their skin glands contains a poisonous substance (phrynin), acrid enough to be felt on tongue or eyes, and probably conducive to the safety of the toads. Although regarded with disgust by the ignorant, the toad is an inoffensive and useful animal, and destroys injurious insects.

The Natterjacks or Rush Toads are rare in Britain, though Gilbert White found them more numerous than common toads in his garden. 'It is of a light yellowish-brown colour, clouded with a dull olive, and there is a bright yellow line running down the back. It is found in dry situations. It is less timid than the common toad, and its eyes are more prominent, its warts larger, its tadpoles smaller, their metamorphoses much shorter.' It has a strong repulsive smell. The gait is more like walking or running than the crawling of the common toad.

The genus Bufo includes over seventy species. These are widely distributed over most parts of the continents, but are most abundant in tropical regions. The largest, *B. marinus* of tropical America, measures 8 inches in length. Some, e.g. *B. typhonius*, have bony ridges on the head; some, e.g. *B. compactilis* of Mexico, have a shovel-like hand modified for digging. A really venomous toad is found in the Argentine Republic (see Hudson's *Naturalist in La Plata*, 1892). Among the other genera may be noted the burrowing Rhinophrynus of Mexico, the Australian Pseudophryne, the Cuban Peltaphryne, the Central American Cranopsis, which differ considerably as regards the degree of ossification in the skull. Among the amphibians which are more nearly related to toads than to frogs are the Horned Toad (Ceratophrys), the Tree-frogs (q.v.; Hylidæ), the Fire-bellied Toad (*Bombinator igneus*) common in Germany, and the 'midwife toad' (*Alytes obstetricans*) of western Europe. See Amphibia, Frog.

Toadflax (*Linaria*), a genus of plants of the natural order Scrophularineæ, very closely allied to Snapdragon (q.v.), from which genus it is distinguished chiefly by the spur at the base of the corolla, and the capsule opening by valves or teeth, not by pores. The species are herbaceous perennials or annuals, natives chiefly of the colder and temperate parts of the Old World, of which about 150 have been described. Some of them are natives of Britain, of which the most common is *L. vulgaris*, a species with erect stem 1 to 3 feet high, glaucous linear-lanceolate leaves which thickly cover the stem, and terminal spikes of yellow flowers. It grows in hedges, the borders of cornfields, &c. It possesses purgative and diuretic properties, and a decoction of it is used as a fly-poison; but it is regarded as a troublesome weed by farmers. It has found its way, probably along with grain or other grass seeds, into the United States. A very remarkable monstrosity is sometimes seen in this plant, to which the name *Peloria* has been given, the flower presenting five spurs and five usually imperfect stamens. *L. Cymbalaria*, the Ivy-leaved Toadflax, or the Mother of Thousands, a favourite window-plant with cottagers in many parts of Britain, is frequently to be seen clothing old garden-walls.

Toadstool, a name for almost any large umbrella-shaped Fungus (q.v.), but as a rule understood to refer to a poisonous form as distinguished from a Mushroom (q.v.).

Toast (Late Lat. *tosta*, 'a piece of toast,' from *tostus*, 'scorched' or 'parched') is the name given to bread dried and browned before the fire. So early as the 16th century toasted bread formed a favourite addition to English drinks. Sack was drunk with toast, and so was punch. The practice of drinking healths, particularly that of an entertainer, is one so natural, so likely to spring up spontaneously, that it is impossible to say when it began. Certain it is, however, that it received an artificial development owing to the prevalence of convivial habits in the 17th century. Then it became the fashion to drink not to the health of entertainers only, but to that of each guest, of absent friends, and more especially of the unmarried woman whose attractions were most generally acknowledged. It also became the custom to describe a woman whose health was so drunk as herself 'a toast'—a custom whimsically referred to one particular incident in the *Tatler*, No. 24 (1709). Whatever may be the origin of the use of the word 'toast' in this sense, we now apply it not only to any person, but to any sentiment mentioned with honour before drinking. Both French and Germans have adopted the word from us. See Chambers's *Book of Days;* Valpy's *History of Toasting* (1881); and six long lists of toasts and sentiments in *Notes and Queries* (1888).

Tobacco. The origin of the word is uncertain, but it is generally supposed to have been derived from *tabaco* or *tabae*, the West Indian or Carib name of the instrument in which the leaves were smoked by the natives. The plant belongs to the genus Nicotiana, of the order Solanaceæ. The various species are mostly herbaceous, rarely shrubby, generally with large broad leaves, and covered all over with small clammy hairs. There are said to be in all about fifty species of the plant, with many varieties belonging to each, but of these three stand out in importance apart from the rest. The first of them is the *Nicotiana tabacum*, or American tobacco, which furnishes the bulk of the tobacco of commerce. It is a handsome plant, standing sometimes 6 or 7 feet high, with large oblong leaves which embrace the stem at their base, and with a pink or rose-coloured flower. It is now grown in all parts of the world, and the commercial American tobacco is almost exclusively of this species, although the varieties differ so widely as sometimes to give rise to a doubt as to whether they are not of different species. It includes, amongst other kinds, the famous Virginian, Kentucky, Maryland, and Havana tobaccos.

Fig. 1.—American Tobacco (*Nicotiana tabacum*).

The *N. rustica* is a smaller plant, about 3 or 4 feet in height, with leaves of a more ovate form which are attached to the stem by stalks, and with a green flower. It is a native of America, but is now cultivated chiefly in Europe, Asia, and Africa, and furnishes the Turkish, Syrian, and probably the Latakia tobaccos of commerce. It is a hardy plant, and ripens earlier than *N. tabacum*. It is called green tobacco, because the leaves in drying do not entirely change to brown.

The *N. persica*, which furnishes the famous mild Shiraz tobacco, is a native of Persia, and has oblong stem-leaves and a white flower. The *N. finis*, popular in the private gardens of England, is often a long straggling plant with small leaves widely separated, but by continually nipping the stem it may be made to assume a bushy form. The flower is white and droops somewhat during the day, but towards sunset it opens out, becomes firm, and then emits for the remainder of the evening a powerful and delicious perfume, which is, of course, quite unlike that of prepared tobacco.

Fig. 2.—Syrian Tobacco (*Nicotiana rustica*).

History.—It is a matter of conjecture whether the use of tobacco as a narcotic was known in the East before the discovery of America. It is possible that the Chinese had long been accustomed to smoking it. The habit, however, did not spread to surrounding countries; whereas on the introduction of tobacco into Europe from America its use rapidly extended and soon became very prevalent in Oriental countries. The custom was in full force in America when that continent was first discovered by Columbus. The natives of the West Indies at that time made the tobacco into cylindrical rolls wrapped in maize-leaf.

Fra Romano Pane, whom Columbus had left behind in Hayti, in 1496 wrote Peter Martyr an account of tobacco; but an exact description of the plant was first given in 1525 by Gonzalo Hernandez de Oviedo, viceroy of San Domingo, who also introduced it into Europe, and cultivated it as an ornamental plant in Spain. Its medicinal properties caused its cultivation to spread to other European countries. Jean Nicot, French ambassador at Lisbon, purchased some seed there which had just been brought over from Florida, and sent some of it home. In 1561, upon his return, he presented some of the plants to Catharine de' Medici. Various names were given to the plant at this time, but finally it was designated *Nicotiana*, and this word, which has been retained by botanists, gives rise to Nicotine, the name of the characteristic alkaloid of the plant. The custom of smoking the dried leaves quickly succeeded the cultivation, to be followed soon after by the habit of snuffing—luxuries at first confined to the wealthy. Therewith commenced a literary warfare, not yet ended, in which the vituperators of the 'stinking habit' produced most of the writings. Popes Urban VIII. and Innocent XI. issued decrees. Sultans of Turkey made smoking a crime punishable by the offenders having their pipes thrust through their noses. In Russia the noses of smokers were cut off. Into England tobacco was

first brought by Sir John Hawkins in 1565. Probably Sir Walter Raleigh had much to do with its popularity by encouraging its growth in 1586, but he was not the introducer; we read in Lobel's *Stirpium Adversaria Nova* (Lond. 1571) that tobacco was at that time successfully cultivated in England and Scotland.

In 1602 appeared the first book against its use, *Work for Chimney Sweepers*. In the same year came *A Defence of Tobacco*; and in 1604 the famous *Counterblaste to Tobacco* of James I., in which that monarch expressed his disapproval of smoking in the following terms: 'A custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the black, stinking fume thereof nearest resembling the horrible Stygian smoke of the pit that is bottomless.' In 1614 the Star-chamber imposed a tax on tobacco, and at about this time stipulations began to appear in respect to responsible appointments, one of the necessary qualifications of a teacher being that he should be 'no puffer of tobacco.' All this proved of little or no avail, and plantations sprang up in all parts of the country. Under Charles I. denunciations continued to issue forth until it was discovered that by taxation a considerable addition to the revenue of the crown could be realised. It was Charles II. who forbade the cultivation in England, and placed a duty on the imported article. Shakespeare makes no reference to the use of tobacco. Ben Jonson, knowing the prejudice of James I., roundly abused the weed in his *Metamorphos'd Gypsies* (1621).

Consumption and Use.—The consumption of tobacco at the present time is greater than it ever was. Thus the annual consumption per head of population in England was 11·7 oz. in 1821, 16·3 oz. in 1851, 22·3 oz. in 1881, and close upon 26 oz. in 1891, the quantity consumed in the latter year being 60,929,915 lb. for a population of about 38 millions. The present average for the whole of Europe is calculated at 2¼ lb. for each inhabitant, which is of course 3 oz. per month. Taking the number of smokers as 30 per cent. of the whole population—a fair proportion, allowing for women, children, and non-smokers—it will be seen that throughout Europe each smoker on the average is responsible for 10 oz. of tobacco per month, or about 2½ oz. per week. In England the quantity is below this—1⅔ oz. per week. A careful German estimate thus states the annual consumption in the various European countries: Holland, a trifle over 7 lb. for each inhabitant; Austria, 3·8 lb.; Denmark, 3·7 lb.; Switzerland, 3·3 lb.; Belgium, 3·2 lb.; Germany, 3 lb.; Norway, 2·3 lb.; France, 2·1 lb.; Sweden, nearly 2 lb.; Spain, 1·7 lb.; Great Britain and Ireland, 1·34 lb.; Italy, 1·25 lb.; and Russia, 1·2 lb. In the United States the amount is 4½ lb. Therefore it follows that each smoker in Holland must consume close upon 8 oz. per week, and in the United States about 5 oz. In Turkey the pipe is omnipresent; in many Asiatic countries all classes and both sexes smoke. Until recently a large quantity of tobacco used to be disposed of as snuff, but the habit of snuffing has decreased very rapidly, and 'plugging' or stuffing the nostrils with quids of tobacco has died out altogether. Chewing is now practised by Englishmen chiefly as a consequence of restrictions placed upon smoking, as, for instance, by sailors at sea and by workmen during working hours; it is comparatively common in the United States. In the early days of smoking, when the price of tobacco was high, it was usual to expel the smoke through the nostrils, as is still the custom of some cigarette smokers.

Cultivation.—Although the tobacco-plant is essentially a tropical one, it readily acclimatises itself to temperate regions, and the hardier kinds can be easily cultivated in comparatively cold climates; but the produce is less valuable the farther north we go, and in some countries, as in Germany, tobacco deteriorates if continually grown from its own seed. Unquestionably the best varieties are those of the tropical countries. One of the most remarkable characteristics of the plant is its rapacious appetite for mineral constituents or what ultimately becomes the ash; and it very soon drains the soil of all its nourishing food. The plant is not over particular as to the quality of the mineral constituents, which, nevertheless, materially affect the quality of the leaf. For instance, if salt is employed as a fertiliser the plant will take up enormous quantities of its chlorine—an element with which it can do without almost entirely—and will be ruined by this as regards its burning properties. Then again, a lime soil will produce a large crop, but the general quality will be somewhat impaired by it. The size of the leaf or the fullness of the crop is no guarantee that that crop will produce a good tobacco. The best kind of soil is an alluvial or a light sandy one containing plenty of potash. In America it is found that on new land the plant has larger stems and fibres than on old, the leaves have a coarse texture, and the tobacco a strong acrid taste, although at the same time the yield is larger. Generally speaking, old soil is preferred, not only because it produces a sweeter tobacco, but because it is more easily prepared. The soil should be watched and deficiencies made good. Potash should be present in larger quantity than is necessary for ordinary agriculture, and when deficient should be added in the form of sulphate. In growing the small garden plant the ash of smoked tobacco may be advantageously used by throwing it on the adjacent mould.

The details of the cultivation vary of necessity according to the climate and the country in which it is carried on, but the following is a general description of what usually takes place. The seed-bed, which should be a light friable soil, is well broken up to a depth of 1½ foot some months before sowing. A drain is dug round it after the style of an asparagus-bed, and a brush heap is burned over the ground to kill weeds and supply potash. The seed, which is very small (one ounce containing about 100,000), is mixed with wood-ashes or sand to assist in its even distribution, and is sown in America between the middle of March and the early part of April. About half an ounce of seed is usually required to produce plants necessary for an acre. In cold climates the seeds are sown in hotbeds. When the seed has been sown the bed is covered first with a thin layer of manure, then with a sprinkling of ashes to keep off ants, and finally with cut straw and small branches of trees to protect the seedlings from cold. In India protection from sun and rain is necessary. The soil is kept moist but not wet, and the plants, which appear in about a week, require frequent but gentle watering. They are thinned out after two or three weeks, and in about seven or eight they are transplanted into the fields. The field is prepared by several ploughings, and by being ridged or raised into hillocks about 2 or 3 feet apart. These ridges or hillocks are flattened at the top and the seedlings planted in small hollows on them, one seedling to each hillock, or, in the case of the ridges, about 3 feet apart. If the weather is dry the plants should be watered night and morning. They rapidly shoot up, and are then watched carefully for insects—in some parts a flock of turkeys being kept for this purpose. When the flower begins to shoot it is nipped off, so that it shall not take away from the leaves any of the nutriment of the plant. This 'topping' is not done in Turkey and some eastern

countries where small leaves are required, and where leaves, buds, and flowers are all used. Generally the leaves are classified into three sorts—the strongest nearest the roots, the medium in the middle of the plant, and the mild at the top. The number and the quality of the leaves may be regulated by nipping off the stem at any desired stage of its growth. Thus a plant may be made to yield eight or ten leaves of a strong flavour, a few more than this of a medium strength, or a still larger number of a mild kind. After the plant has been nipped 'suckers' begin to appear, and must be removed as quickly and as completely as possible. This, together with the removal of worms, can only be adequately performed by a daily examination. Nothing else is now required to be done until the leaves are sufficiently ripe for the harvest, which generally takes place in August or the early part of September. In some places a uniform quality of leaves is aimed at by first cutting a few of them nearest the roots, then leaving the plant eight or ten days for the other leaves to strengthen, cutting a few more of the lower ones, and so on, until the stem is stripped. Another plan is to bring down the whole plant at once by cutting the stem close to the ground.

In India, Ceylon, and some other eastern countries the leaves are simply sun-dried and sent into the market, while in Europe artificial drying is resorted to in the shape of drying-houses heated generally to a temperature of about 70° to 90° F. In America both natural and artificial methods are adopted, nearly always conjointly. Sometimes the leaves are hung in sheds till the spring and then bulked, but more often they are dried in the drying-house, after perhaps being partly sun-dried, then placed in heaps, covered over, and left for a week or two to ferment, with occasional turning to prevent excessive fermentation and firing. The leaves are then sorted, tied into bundles of about a dozen, called 'hands,' and packed under pressure in barrels or hogsheads.

Manufacture.—Tobacco may be selected on account of its colour, its aroma, its body, or its drinking power—i.e. its power of absorbing and retaining water without becoming too wet, a very usefnl kind of tobacco to some manufacturers in past years. Again, it may be chosen as a fiery tobacco which is used to mix with other kinds difficult of burning, while a material like Chinese tobacco, which is of a very light yellow colour, without body and almost flavourless, is bought solely for producing variety of colour in mixtures. Leaves for cigar-making must be of a good colour and fair body, possess a pleasant aroma to begin with, emit an agreeable odour on burning, have a fairly fine texture, a certain amount of toughness, the ribs and veins must be small, and finally, they must answer the burning test, which is that the leaves should continue to smoulder after they have once been lighted.

Tobacco is imported always tightly compressed and apparently quite dry and crisp. Sometimes it is in the full leaf in bundles tied round by one of its own leaves; sometimes the midribs have been removed—when the material is then known as 'strips.' American varieties are exported in these conditions roughly and tightly packed in hogsheads. The more tender kinds, such as Turkish, Chinese, and Ceylon, are carefully packed leaf upon leaf. The names of some of the better known varieties in the market are those of Virginia, Kentucky, Maryland, Big Frederick, Western (leaf and strips), Indiana, &c. from America; Java, Japan, China, India, and Ceylon from the East; and Turkish and German from Europe. The dry-looking imported article contains from 10 to 20 per cent. of water, or on an average about 14 per cent.; but before manufacture it must be impregnated with more water and steamed, when the leaves rapidly become flaccid and easily open out.

In the manufacture of cigars the leaves, after being thus treated, are stripped of their midribs, smoothed and sorted, the perfect half-leaves being put on one side to be used as wrappers. One of these strips is cut into the shape of a balloon gore, and fragments of imperfect leaves and cuttings, known as the 'fillers,' being placed at one end, the strip is wrapped round them. Over this is then wound spirally a long narrow rectangular slip called the 'wrapper,' commencing at the lighting end and finishing at the pointed or mouth end. The cigars are then gauged and cut to length, dried and packed. Cheroots differ from cigars only in the matter of shape, being open at both ends, generally with one of them much broader than the other. Good cigars should consist of the same tobacco throughout, but very often the seductive wrapper conceals an inferior and even bad material. Cigars are rarely adulterated; the interior is at worst nearly always tobacco of a cheap kind. The best Havana cigars all come from Cuba; but it is a common practice to place home-made cigars in imitation foreign boxes. Cheroots come chiefly from the Philippine Islands. Mexican tobacco has met with much favour of recent years for cigar-making. The high import duty for cigars has fostered the practice of importing the leaves, on which less duty is paid, and manufacturing them in England. The difference between the foreign and British made articles is easily detected, and, as a rule, the latter are more glossy, better made, and more uniform in their appearance than the former. In the United States cigar-making is an important industry, and the best brands of 'domestics' bring a good price. Cigar-smoking in northern Europe is of recent origin. The first cigar-shop in Germany was opened in Hamburg in 1788. French soldiers brought the habit of smoking from Spain early in the 19th century.

The greater portion of the imported leaves, however, is manufactured into pipe tobacco, of which there are two classes—the *cut* and the *cake* or *twist*. As a rule, for the former class the leaves are stripped of the midrib, damped, allowed to ferment a little, and are then placed in a square iron box and pressed into a large cake. The dark-coloured liquor which is squeezed out is used as 'sauce' for a stronger product. The cake is then cut in a cutting machine into shreds of the desired fineness. The cuttings are gently steamed, pulled, well mixed, and scented if desired. *Shag* is prepared in this way from a rather strong variety of leaf. In the case of *Bird's-eye* the midribs are not removed. *Returns* is so called from being prepared from broken and rejected pieces and siftings.

In the second class there are also many kinds, such as *Cavendish*, *Negrohead*, *Pigtail*, *Bogie*, &c. The strongest kinds of leaf are employed in their preparation, and generally plenty of sauce is mixed in. For *Cavendish* the leaves are stripped, sauced, fermented, and are then laid one upon another and pressed into cakes of the desired size. They are sometimes made into sticks about 9 inches long and 1 inch thick, which are then laid across each other equally and pressed together: this kind is called *Negrohead*. In the case of twist tobacco the stripped fermented leaves are twisted either by hand or by a spinning-wheel after the style of making string. The rope so obtained, if thin, is known as *Pigtail*, and if thick, generally as *Bogie*. It is wound into balls or reels. All these kinds are oiled with sweet-oil, which prevents them from sticking together and from becoming too dry. In America mild cakes are impregnated with molasses

or liquorice to give them a sweet flavour in chewing, but in England the sale of such tobacco is illegal. Cigarettes are usually made of the Syrian species, such as fine-cut Turkish, Salonica, &c.; but American tobacco has of late years been rather extensively used.

When the British duty on tobacco was reduced in 1887 there was a limit placed on the amount of water to be allowed in the manufactured article. The maximum amount permitted is 35 per cent., whereas in cake and twist 45 to 50 per cent. used to be of frequent occurrence. The adulterants of tobacco are legion. All kinds of vegetable substances, gums, saccharin, and mineral matters have at different times been detected. Manufacturers in Britain are prohibited, under a penalty of £200, not only from using but from having in their possession sugar, honey, molasses, treacle, leaves, herbs, or plants, powdered wood, weeds, ground or unground, roasted grain, chicory, lime, sand, umber, ochre, or anything capable of being used to increase the weight of tobacco and snuff. Any water over and above 35 per cent., of course, is now an adulterant; the excise penalty in this case being £50 and the forfeiture of the tobacco.

Snuff used to be made from tobacco leaves, but now it is prepared almost entirely from the stalks and ribs which are not used by the tobacco-manufacturer. The dry snuffs include the well-known Welsh, Scotch, and Irish varieties, and are prepared by finely grinding the stalks in a mortar after they have been allowed to ferment. The characteristic odour of the Irish and Welsh kinds is obtained by gently roasting the stalks previous to grinding. The moist snuffs include most of the preparations with fanciful names. These are generally made by grinding the stalks wet, allowing the fermentation to take place after grinding, mixing with various salts sanctioned by the excise, scenting and moistening to the desired degree. Snuff has been, and is sometimes now, adulterated to an enormous extent. It is no uncommon thing at the present day for the tobacco-manufacturer to add the sweepings of his whole factory to the parcel of scrap pieces intended for the snuff-maker. Besides this, many adulterants are purposely added, including many kinds of vegetable matter, salts, red-lead, chromate of lead, and oxide of iron.

Constituents.—The green leaf, and even the bulk of the dry imported leaf, contains a large ratio of complex organic bodies which retard combustion, and which, on forcing the burning, give off very objectionable odours. It is the processes of curing, fermenting, and manufacturing which get rid of or modify these objectionable bodies, and so render the material fit for use. Excessive fermentation has to be avoided, especially with cigar tobacco, because it blackens the leaves and produces ammonia compounds. Some leaves, especially those grown in tropical climates, do not require fermentation. The mineral constituents remain the same throughout, except in their combination with the organic substances, and on burning they constitute the incombustible residue or ash. The ash should be white or grayish white in colour, and not excessive in quantity—generally between 12 and 20 per cent. of the dry leaf; redness denotes iron in the soil, and blackness is due to carbon, the result of imperfect combustion. The characteristic constituent, however, of all tobacco is the alkaloid *nicotine*, which varies in quantity from about 1 to 9 per cent. The best flavoured kinds, such as Havana and Manilla, contain only about 2 to 3 per cent., while some of the commoner varieties of French and German run up to 9 per cent. American Virginia and Kentucky average about 4 or 5 per cent. It is believed by many that the spotted appearance is a good indication. The origin of these spots has given rise to many opinions; but it is now understood that the pale spots are formed by the sun's heat being concentrated by transparent globules on to the leaf and locally burning.

Commerce.—The revenue of Great Britain from the import duty on tobacco is close upon 10 millions sterling, and in 1891 constituted for the first time more than half the whole revenue of the customs department. This is, of course, because it is taxed so enormously out of proportion to its own value, and so much more heavily than the other articles. The duty, which was raised in 1878 from 3s. 2d. to 3s. 6d., was lowered again, with a restriction as to the ultimate moisture, in 1887, and the present rates are as follows: Unmanufactured, containing 10 per cent. or more moisture, 3s. 2d. per lb.; unmanufactured, containing less than 10 per cent. moisture, 3s. 6d. per lb.; cigars, 5s. per lb.; cavendish, 4s. 6d. per lb.; other manufactured tobacco, 4s. per lb. As the price of unmanufactured tobacco in bond varies roughly between 4d. and 1s. per lb., it will be seen that the amount paid as duty is nearly ten times the actual value of the material in the case of the poorer qualities, and more than three times in that of the better kinds. This disproportionate tax naturally offers a strong temptation for surreptitious trading or Smuggling (q.v.). The authorities keep up a rigorous supervision to prevent it, and are assisted in their work by the stringency of the law, which stipulates that no packet be allowed to be imported of less weight than 80 lb. (except samples), and this must not arrive in any vessel of less than 120 tons burden. Furthermore, the imports are not allowed to enter the United Kingdom except through specified ports duly approved by the commissioners. Passengers entering the United Kingdom from abroad may carry 8 oz. of cigars or manufactured tobacco free of duty, but persons from the Channel Islands are allowed only 4 oz. Duty can be paid on amounts not exceeding 3 lb. by passengers from the Continent (unless they are frequent visitors), and on any quantity up to 7 lb. if from the West Indies and other more distant parts. Of unmanufactured tobacco the traveller may pay duty on any quantity not exceeding 9 lb. If these conditions are evaded the goods are always confiscated, and usually double or treble duty is charged.

The actual revenue receipts for tobacco for 1897 were £11,018,000, an increase of £1,484,000 over 1890, the total revenue from the customs for 1897 being £21,266,000. The imports in 1897 were 80,728,432 lb. of unmanufactured tobacco and 4,615,123 lb. of manufactured and snuff, together worth £4,066,581; in 1891, respectively, 59,996,176 lb. and 63,493,554 lb., worth £3,423,971. The annual exports are about 7,000,000 lb. of unmanufactured and 2,000,000 lb. of manufactured, worth over £500,000.

More than two-thirds of the unmanufactured tobacco comes from the United States, a considerable amount from Germany, and smaller quantities from Japan, India, China, and other countries. Cigars are chiefly brought from the West Indies, Philippine Islands, Germany, and of recent years Mexico. The country which derives the greatest revenue from tobacco is France, where the home-grown crops are purchased by the government. Then follow in the order named the United Kingdom, Austria-Hungary, Spain, and Italy.

Physiological Effects.—Tobacco acts in various ways on the system, depending, first, on the individual, and secondly, on the time and circumstances of its being consumed. It acts most frequently as a sedative or a narcotic. In some instances it will rouse the sluggish mind into

activity, while in others it will moderate excessive mental excitement. It will often correct the disagreeable effects of nervousness; while, on the other hand, it will likewise act as a laxative. The most noticeable characteristics perhaps are the effects of smoking on the nervous system in such cases as those in which it is upset by mental distress or anxiety. At the same time it must not be forgotten that there are persons whose nerves are disarranged and quite upset by smoking. By such people the habit should be tabooed altogether. Others again are only inconvenienced after an excess, while there are those who can stand any amount. Consequently, if the use of tobacco is ever to be governed by a single law, it will be by that of common sense. The amount to be consumed must be regulated by the individual who consumes it. Although even excess has never been known to originate a specific disease, still it reduces the system to a low condition, and unfits it to fight against ailments brought on by other causes. Until the system is near maturity, tobacco should be only lightly indulged in, or avoided *in toto*, as it acts prejudicially, even in small doses, in early life, and if used in excess is liable to have a permanent ill effect. The immediate effects of tobacco poisoning are very transitory, and they soon work off.

The usual effects of an overdose of tobacco are faintness, nausea, giddiness, general relaxation of the muscular system, loss of power of the limbs, cold perspiration, and vomiting. In some cases there is purging, and in others a sense of sinking or depression in the region of the heart. Attendant on these symptoms are a dilation of the pupils, dimness of sight, weak pulse, and difficulty of breathing. In mild cases a little stimulant and fresh air are the best remedies. Some of these disturbances of the functions are occasionally felt by the inveterate smoker, who also is liable to suffer from what is known as 'smoker's sore throat.' This makes itself evident by an irritable state of the mucous membrane at the back of the throat, with dryness, producing a tendency to cough and an enlarged, soft, sore condition of the tonsils, which renders it painful to swallow. It may exist without detection for a long time; but if a damp, cold, foggy state of the air arises, the throat becomes troublesome and painful, enlargement of the tonsils is detected, and the symptoms become much aggravated by any attempt to smoke. When smoking is altogether suspended it soon disappears, but it is incurable while the habit is persisted in, although the more troublesome symptoms may be temporarily alleviated.

The combustion of tobacco in smoking is never a complete one. While there are large quantities of carbonic acid and water—the ultimate products of complete organic combustion—produced, there are also many organic substances which are formed or become released by the heat, and which distil over with the gaseous bodies. It is the condensation of these volatile substances in very minute particles, in a similar manner to the condensation of steam at the kettle spout, which gives rise to the appearance of smoke. The colour of the smoke is dependent on the quantity of these substances present, and the rapidity with which they are condensed. The burning of tobacco should be free, with a clean ash, but not too rapid. If it is retarded from any cause, such as the improper fermentation of the leaf, or by containing the wrong mineral constituents, then objectionable products are obtained which possess both a disagreeable taste and odour. Moreover, carbonic oxide—a distinctly poisonous gas—is produced in considerable amount. All these substances tend to create the unpleasantness so often experienced with a badly burning cigar. A large proportion of the nicotine is consumed or destroyed in the burning, the ratio depending on the freeness or completeness of the combustion. The bulk of it, therefore, is not absorbed into the system, as some would make out. Indeed, it is impossible for it to be so, as one ordinary cigar contains enough nicotine to poison two men. A tenth of a grain will kill a medium-sized dog, so that a quarter of an ounce of mild tobacco would contain sufficient to poison twenty or thirty of these animals. The other principal products of the burning are ammonia and its compounds, an empyreumatic oil, and a dark, bitter, resinous substance. The first named is very objectionable both to taste and smell if in undue proportion. The last two are very evident, the former in the odour of stale tobacco, and the other in the bitter taste of the oil in the stem of a foul pipe, and both largely impregnate the smoke. These organic substances begin to be deposited directly they are formed, so that some remains in the mouth, and if the smoke is swallowed or passed through the nostrils much more will be retained and absorbed into the system—certainly an undesirable result.

It will be quite evident that the least harmful method of smoking is the use of a long pipe made of an absorbing material, such as clay or meerschaum. After this a short pipe, then the cigar and cigarette. In the progress of smoking a cigar the oils, &c. partly become condensed in it, and at the same time driven farther along until the end becomes nearly saturated with them. This end piece is often consumed with great eagerness and relish, but it is the most harmful part, and is liable to produce dyspepsia, especially with an empty stomach. The specifically deleterious effects sometimes due to cigarette-smoking may depend on poisonous substances used in preparing the cigarette-papers. The best time for smoking is unquestionably after a meal, and it should not be indulged in immediately before one. The habit of snuff-taking is perhaps the least harmful of the varied uses of tobacco, as the amount consumed must be within reasonable limit. Chewing, on the other hand, is doubtless the most deleterious. Owing to the rapid growth of cigarette-smoking, laws had been passed, up to 1891, in about three-fourths of the United States prohibiting smoking by youths.

Although on its introduction into Europe the cultivation of the plant was advocated on account of its medicinal virtues, it is now very little used for them. It has been found effective in spasmodic cases, but at the present time there is only one preparation in the British Pharmacopœia—an infusion of the leaf in water—and this is rarely used. Nicotine is an antidote in poisoning by strychnine, and *vice versâ* strychnine will act as an antidote to nicotine. An infusion of tobacco is an excellent insect destroyer, and the spraying of the leaves of a plant with water containing it is very effectual. The juice or 'sauce' squeezed out of the leaves in their preparation for tobacco is occasionally sold and used as a sheep-wash.

English-grown Tobacco.—In consequence of the depressed state of agriculture in England, the idea of the home-cultivation of tobacco was started, and in 1886 the necessary permission from the Inland Revenue authorities was obtained, and a fair number of trials were made. The results were so encouraging that permission with less severe restrictions was obtained again for 1887, in which year, with an early start, a thoroughly fair trial was made. Every grower reported favourably on the results of his experiments, and the ability to grow the plant in Britain was fully established. But when the authorities were approached with a view to enable the cultivation to be commenced

in earnest, and as a source of profit to the grower, there was not the slightest hope held out that any facilities would be granted; any scheme likely to interfere with the machinery responsible for the annual collection of £9,000,000 could hardly be viewed with favour by the officials concerned.

Had this been foreseen it would hardly have been necessary to try experiments to show that tobacco could be cultivated in England, since history fully demonstrates the fact. From the time of its introduction down to nearly the end of the 18th century, when it was finally banished, the successful cultivation had always more or less been carried on. James I. and Charles I., of course, prohibited it, but without effect. Charles II., when he commenced to derive revenue from the imported leaves, imposed so heavy a tax on the home-grown article as it was hoped would stop its cultivation. The surreptitious growth was continued, in spite of all laws to the contrary, right down to the reign of George III., when it was finally stopped by an act passed in 1782. The plantations in Yorkshire were then destroyed, and the planters imprisoned and heavily fined—the large sum for those days of £30,000 being exacted as penalties. In Ireland the treatment was less severe, and the culture was not finally stopped until about the year 1831, when it was found to be making too much progress. In those days the profit would be more certain and the competition from foreign markets not so great as now, but against these might be weighed the greater technical knowledge of the modern farmer; and the collecting of duty should be easier now than it was then. The recent experiments may be held to have proved that in many parts of England tobacco might be expected to produce a crop worth £50 an acre, and that there is time in the English summers to ripen a fair quality of leaf. What was grown never had a fair trial in regard to curing. English soil is not all equally suited for tobacco-culture; and the statement that tobacco poisons the land merely means that it drains it of certain constituents which can be supplied again by proper treatment with manures, &c.

The total quantity of tobacco grown in the United States in 1880 was 472,661,159 lb. (of which 171,120,784 lb. were grown in Kentucky); and in 1881–90 the average crop was nearly 490,000,000 lb. The value of a year's crop in 1880–90 varied from $30,000,000 to $45,000,000. The Inland Revenue receipts alone reach some $34,000,000. The exports of unmanufactured tobacco from the United States in 1890 amounted, with stems and trimmings, to 255,647,026 lb., valued at $21,479,556; and of manufactured tobacco, including cigars and cigarettes, the value in the same year was $3,876,045. The total exports in 1897–98 had a value of $26,990,000; the imports in the same year of $9,092,000. Prior to 1890 the import duties ranged from 40 cents to $2·50+25 per cent. *ad valorem*, but under the McKinley tariff they range from 35 cents to $4·50+25 per cent. *ad valorem* per lb.

See works on tobacco and tobacco-growing by Billings and by Lock (1886); on its history and associations by Fairholt (1859; new ed. 1876) and Taylor (1886); Reports and other papers published by the American government; German works on tobacco-growing and manufacturing by Tiedemann (1854), Wagner (5th ed. 1888), and Becker (2d ed. 1883); Bragge's *Bibliotheca Nicotiana* (1880); on English and European tobacco-culture, see a work by Beale (1887), and papers in the *Journal* of the Royal Agricultural Society, vols. xxii. and xxiii.; and on the hygienic question, see Hare, *The Physiological and Pathological Effects of Tobacco* (Phila. and Lond. 1886), and Jolly, *Études Médicales sur le Tabac* (1865).

TOBACCO-PIPES. The oldest tobacco-pipes known are those which have been found in the ancient grave-mounds of the Mississippi Valley. These are in various kinds of stone, some being carved

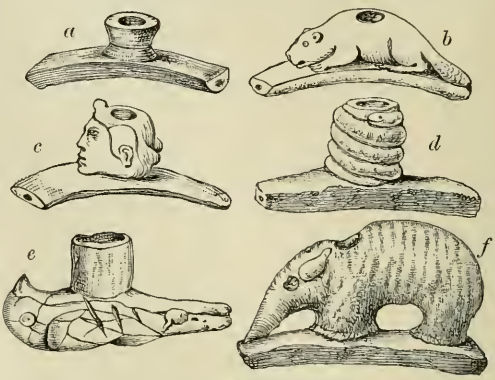

Fig. 3.—Mound Pipes:
a, 'monitor' pipe; *b*, beaver pipe; *c*, pipe carved in the form of a human head; *d*, serpent pipe; *e*, bird pipe; *f*, elephant pipe. (From *American Naturalist*, April 1882.)

into the form of human heads and others into the shape of various animals, but the most common kind have a plain, more or less conical bowl. All have a short, broad, slightly-curved, perforated stem, forming a sort of base for the bowl. Among the animals represented are the beaver, the bear, the seal, the frog, and various kinds of birds. But the most interesting of all are what are called 'elephant-pipes' (fig. 3, *f*), of which only two appear to have been found. These unmistakably represent an animal like the elephant, only the tusks are wanting. As the remains of the Mastodon (q.v.), which, however, had tusks, are found in America, the curious question arises, has this animal become extinct on that continent since the time of the people who carved these pipes? This matter has given rise to an animated controversy among archæologists in the United States, some of whom, apparently without much reason, maintain that the two pipes found are of doubtful authenticity.

Of modern or comparatively modern American pipes, the most interesting are the Calumet (q.v.)

Fig. 4.—Indian Calumet.

or pipe of peace, the tomahawk-pipe (see TOMAHAWK) or war-pipe, and the elaborately and grotesquely carved stone-pipes made by the Indians of the North Pacific coast, which at first glance do not look like tobacco-pipes at all. The pipes of wood and whale's bone made by the Stickeen Indians, in the form of boats bearing houses, are also very curious.

Except what were made in earlier times in America there are, of course, no tobacco-pipes of a date prior to the end of the 16th century. The first common clay-pipes manufactured in Europe were perhaps those of England and Holland. Some of them, of small size, are known as Elfin Celtic, or fairy pipes. Pipes of baked clay show great diversity of shape and ornament. The finest kinds of these were made during the later half of the 18th century at Sèvres, Chelsea, Dresden, Vienna, and other famous European porcelain

works, many clever artists having been employed in decorating them. Porcelain pipes, but mostly of a plain kind, are still largely made in Germany. Modern French clay-pipes often display skilful modelling. Meerschaum-pipes, many of which are exquisitely carved, are made in large numbers in Austria, and artificial meerschaums in much greater quantities. 'Briar-root' pipes are cut out of the wood of the tree heath (*Erica arborea*; Fr. *bruyère*), which grows in southern France and Italy, and are manufactured at Nuremberg and at St Claude in the east of France.

A great variety of other materials are or have been used for tobacco-pipes. Among these may be mentioned silver, brass, and other metals, glass, ivory, horn, cane, bamboo, and various kinds of stone. Equally numerous have been the ways of decorating their stems and bowls, such as by enamelling, chasing, engraving, carving, and inlaying. The same thing may be said of pipe-cases and tobacco-boxes. In some parts of the world tobacco-pouches are beautifully embroidered. The Hookah (q.v.) or narghileh bowls of India and Persia are often most elaborately ornamented. Pipes made by the Kookies (Manipur) have reservoirs for collecting the tobacco-juice, which is afterwards put into the mouth. The pipes used by the Kirghiz, or at least some of them, have three bowls. Some singular forms of tobacco-pipes are found in uncivilised countries. In New Guinea they consist of capacious hollow cylinders of bamboo, the large volume of smoke which these contain being drawn into the mouth by an aperture at the end. In the Zambesi district of East Africa the stems are formed of an antelope's entire horn, from the middle of which a vertical piece of wood rises, carrying the bowl. The western Eskimo uses pipes with remarkably small metal bowls, and such pipes, though different in form, occur also in China and Japan. The largest collection (7000) of tobacco-pipes ever formed was that made by William Bragge of Birmingham (1823–84), of which he printed a catalogue, *Bibliotheca Nicotiana* (1880). This collection, now dispersed, included almost every known kind of pipe, as well as varieties of tobacco and snuff boxes.

Tobago, the most southerly of the Windward Islands belonging to Britain, lies 75 miles SE. of Grenada and 18½ miles NE. of Trinidad, is 32 miles long, from 6 to 7½ broad, and has an area of 114 sq. m. The island was discovered by Columbus in 1498, and named by him Assumption; the name of Tobago is supposed to have arisen from the free use of tobacco by the Caribs when first visited by Europeans. It has been frequently contested between Dutch, Spaniards, and French, but came into British possession in 1763. The island is volcanic, its surface being irregular and picturesque, and abounding in conical hills and spurs, all connected by a ridge running through the interior, the greatest elevation of which is 1800 feet above the level of the sea. From the high ridge descend deep and narrow ravines, which terminate in small alluvial plains. Scarborough is its chief town, pleasantly situated on the south side, and at the base of a conical hill rising 425 feet in altitude, crowned by Fort King George, now without garrison. The chief exports are rum, molasses, cocoa-nuts, and live-stock to the amount of from £20,000 to £40,000. The imports run from £20,000 to £30,000. Pop. (1880) 19,324; (1890) 20,727. The island was united with the colony of Trinidad in 1889, and has a commissioner appointed by the governor.

Tobermory. See Mull.

Tobit, The Book of, one of the most curious and interesting of the Old Testament apocrypha, tells of Tobit, and Tobias his son. Tobit was a pious, upright, and God-fearing Israelite of the tribe of Naphtali, who had been carried captive to Nineveh by 'Enemassar' (Shalmaneser). Among his many good works was the practice of defying the prohibition of the Assyrian kings by secretly burying the bodies of his slain fellow-countrymen. He was at last discovered, and deprived of all his goods in consequence. To add to his misfortune, through an accident that befell him as he slept in the open air one night, he became blind. In his poverty and distress he resolves to send his son Tobias to Rhagæ (Rai) in Media to recover an old debt from a friend. Tobias finds a companion for the long journey in an unknown youth (really the archangel Raphael) who on the journey gives him much valuable information and advice. Acting on this, he catches a great 'fish' in the Tigris, and secures its heart, liver, and gall. By means of the first two he is able to deliver from the power of the evil spirit Asmodeus his lovely cousin Sara, daughter of Raguel, at Ecbatana, whom he marries and, after recovering the debt for which he had been sent, leads back to his father's house. Arrived at home, he is able with the gall of the fish to cure his father's blindness. The book closes with Tobit's psalm of thanksgiving, and relates how he enjoyed a hundred years' happiness after these events, Tobias also living to see the age of 127. The Book of Tobit exists in Greek, Latin, Syriac, Aramaic, and Hebrew. There is little doubt that the Greek is the original. Of this there are two recensions, a shorter and a longer, the shorter being the one generally current, and probably the earlier. The longer occurs in the Codex Sinaiticus, and has been published by Reusch (1870). It is represented by the Latin, Aramaic, Hebrew, and partly also by the Syriac version. The Hebrew version was published by Münster as early as 1542; the Aramaic was first edited by Neubauer in 1878. If the Greek is the original, the book can hardly have been written before the 2d century B.C., and it can perhaps be most appropriately assigned to the period of the Jewish struggles for independence, when, for example, it was the complaint of the faithful that their oppressor had cast out many unburied (2 Macc. v. 10). Again, if originally written in Greek, it probably had its origin in Egypt. In fact it has never been widely known in the Syrian Church; its author's acquaintance with the eastern localities he names is superficial and not always accurate; and it has been pointed out that the 'fish' caught in the Tigris is most probably in reality the Egyptian crocodile, of which we know from ancient medical writers that the smoke of its liver used to be regarded as a cure for epilepsy, and its gall for leucoma. But those who trace the story to a Persian origin are also so far justified by certain facts. Asmodeus is manifestly the Persian evil spirit Aeshmâ Daevâ, and Raphael has the attributes of the protecting spirit Çraosha. The presence of the dog, too, who goes out and returns with Tobias and Raphael denotes rather a Persian than a pure Hebrew source, the Jews regarding that animal as unclean, while with the Iranians it is sacred, and the companion of Çraosha.

The nature of the additions to Tobit in the larger versions can be seen by the English reader in Churton's *Uncanonical and Apocryphal Scriptures.* The book has been commented on by Fritzsche (1853), Reusch (1857), Sengelmann (1857), and Gutberlet (1877). See Schürer, *Gesch. d. Jüd. Volkes,* vol. ii. (Eng. trans.); and A. Neubauer, *The Book of Tobit: a Chaldee Text* (1877).

Tobogganing. See Sleighs.

Tobolsk, a town of western Siberia, capital of a government, stands at the confluence of the Irtish and the Tobol, nearly 2000 miles east of St

Petersburg. It is well built, with timber houses and wide and regular streets, and its position on the two great rivers is picturesque; but its situation, considerably north of the great commercial highway between Russia and Siberia, and at a distance from the more productive regions of the country, is unfavourable for the development of commerce. Pop. 25,130.—For the *government*, see Russia; also Siberia.

Tobo'so, El, a small town (pop. 1904) in the Spanish district of La Mancha, 60 miles SE. of Toledo, the home of Don Quixote's peerless Dulcinea del Toboso.

Tocantins, an important river of Brazil, rises in the state of Goyaz, flows north through the state of Pará, and finally, after a course of 1500 miles, widens into the Pará (q.v.), 138 miles from the Atlantic. Its principal affluent is the Araguay (1600 miles), which joins it at the northern extremity of Goyaz, and bears along a greater volume of water than the stream to which it is tributary. The Tocantins is traversed by steamers to 400 miles from the sea; and above the line of falls and rapids 400 miles more is navigable.

Toccata. See Music, Vol. VII. p. 358.

Tocqueville, Alexis Charles Henri Chérel de, was born at Verneuil, in the department of Seine-et-Oise, 29th July 1805. His father, the head of the ancient family of Tocqueville in Normandy, whose wife was a granddaughter of Malesherbes, narrowly escaped the guillotine, but did not emigrate, and, having preserved his property, reassumed in 1815 the title of Count. Young Tocqueville was called to the bar at Paris in 1825, and after a short tour in Italy became an assistant magistrate at Versailles. In 1831 he accepted a government mission to America, to report on the working of the penitentiary system, but the chief fruit of which was his great work, *De la Démocratie en Amérique* (1835; 15th ed. 1868; Eng. trans. 1835). *Democracy*, which was the first carefully thought out book written in Europe on the subject, made at once a great sensation. The accuracy of the statements, the skill with which the matter had been digested, and the beauty of the style were loudly praised by critics. The author was described as the continuator of Montesquieu, and the greatest political writer of his time. He became successively a member of the Academy of Moral Sciences and of the French Academy. The work is a fair and lucid statement from a moderate point of view; but his knowledge was hardly sufficient to bear the whole deductive structure of system which he built on it. In 1835 De Tocqueville visited England, where his work had made him known, and where he received an enthusiastic welcome from the leaders of the Whig party. In the same year he married Miss Mottley, an Englishwoman. He shortly afterwards, by a family arrangement, entered into possession of Tocqueville. He stood in 1837 as candidate for the Chamber of Deputies, and was defeated; but two years later was returned by his neighbours, the Norman farmers, by an overwhelming majority. As a speaker De Tocqueville did not succeed, but he exercised great influence on the legislature. Immediately after the revolution of 1848 he was the most formidable opponent of the Socialists and extreme Republicans, and as strenuously opposed Louis Napoleon. He became, however, in 1849 vice-president of the Assembly, and from June to October in the same year was minister of Foreign Affairs. At this time he vindicated the policy of the expedition to Rome, on the ground that it would secure liberal institutions to the States of the Church. After the *coup d'état* he returned to Tocqueville, where he devoted himself to agricultural pursuits. He there wrote *L'ancien Régime et la Révolution* (1856; Eng. trans. same year), a work now regarded as defective, not merely in width and depth of knowledge, but in being too favourable to the Revolution. He had also written a work on the reign of Louis XV. (1846–50). In June 1858 he broke a blood-vessel, and took up his abode at Cannes, where he died, 16th April 1859. Tocqueville's *Œuvres et Correspondance Inédites* were published in 2 vols. (1860), by his friend M. de Beaumont, with a biographical notice (trans. as *Memoirs, Letters, and Remains*, 1861). A collected edition of his works appeared at Paris in 9 vols. in 1860–65. See his *Souvenirs* (trans. 1896); a monograph by Jaques (Vienna, 1876); and his *Conversations and Correspondence with Nassau Senior* (2 vols. 1872).

Todas. See Neilgherry.

Toddy, the name given in the East Indies to the fermented juice of various palms from which Arrack (q.v.) is distilled. It is applied in Britain to a mixture of whisky, sugar, and hot water, which forms a popular drink in Scotland.

Todhunter, Isaac, mathematician, was born at Rye in 1820, studied at University College, London, served some time as a tutor, and so was enabled to enter St John's College, Cambridge, where in 1848 he graduated senior wrangler and Smith's prizeman. Elected to a fellowship in his college, he became eventually its principal mathematical lecturer, and ere long his handbooks of Algebra, Geometry, Conic Sections, Trigonometry, Mensuration, and Mechanics made his name known, if not always honoured, in every schoolroom in England. For more advanced students his indefatigable energy and rare faculty of exposition provided also manuals on the Differential and the Integral Calculus, Analytical Statics, Plane Co-ordinate Geometry, and Analytical Geometry. He died 1st March 1884.

Todleben, Eduard Ivanovitch, Russian general, was born of German descent at Mitau in Courland, 20th May 1818. After studying at Riga and St Petersburg, he distinguished himself as a lieutenant of engineers in the Caucasus, and was with the engineer corps when the Russian army entered the Danubian Principalities in 1853. His genius as a military engineer was discovered before the Russian army crossed the Pruth, on its retreat from the Principalities; and when the French and English undertook the siege of Sebastopol, Colonel Todleben was sent to assist in its defence. He arrived in the middle of April, and the fortifications were soon placed under his direction. The prodigious activity displayed by the Russians in making good the damage sustained by the heavy fire of the enemy filled the allies with astonishment. Everywhere massive ramparts of earthworks, mounted with formidable batteries, rose up as if by magic at each threatened point within the line of defence. During the latter part of the siege he was wounded in the leg. For services in the siege he was created a general, decorated, and made director of the engineer department in the war office. In 1865 he visited England, and was cordially received. He held no very important post till disasters began to befall the Russian army during the Turkish war. Todleben was remembered, and was called to undertake the siege of Plevna (q.v.), which, after a brilliant defence, he took. He was subsequently made commander-in-chief in Bulgaria, and at the time of his death, 1st July 1884, was governor of Odessa.

He wrote an admirable account of the defence of Sebastopol (French ed. 1864). There are Lives by Brialmont (Brussels, 1884) and Krähmer (Berlin, 1888). See Kinglake's and Hamley's histories of the Crimean War.

Todmorden, a market-town on the border of Yorkshire and Lancashire, prettily situated among hills on the Calder, 9 miles N. by E. of Rochdale, 18½ NNE. of Manchester, and 13 W. of Halifax. The classical town-hall was erected in 1875, and in front of it is a bronze statue by Foley of John Fielden, M.P. (1784–1849), the founder here of an enormous cotton-mill. Coal abounds in the vicinity. Pop. (1871) 21,764; (1891) 24,725.

Tofana. See POISON.

Toga (from Lat. *tego*, 'I cover'), the principal outer garment of the Romans, was a thick woollen cloth, originally worn over a loin-cloth or apron. When the tunic was adopted the toga became more bulky and was worn in a looser manner. It was probably of Etruscan origin, and yet it came to be considered the distinctive badge of the Roman citizen, whence the Roman people are called *togati* or *gens togata*. Scholars are divided as to its shape, some making it elliptical with pointed ends, while others declare that the most usual form was a crescent, the back of which was an elliptical curve with a circular segment of cloth sewn on to its concave side. The toga of ordinary life was white in colour. The *toga prætexta* had a broad purple border, and was worn by children and by the curule magistrates and censors. When the young Roman was declared to be legally of age he assumed the ordinary toga, on this account called the *toga virilis*. Persons in mourning (*sordidati*) and persons under impeachment wore the *toga pulla*, a garment of a dark colour; while those who were seeking office were wont to dress themselves out in garments which had been made artificially bright by the help of chalk—hence their name of *candidati*. Under the emperors the toga as an article of common wear fell into disuse; but it continued to be worn by magistrates and people on all official occasions.

Togo, in Togoland, since 1884 a German protectorate on the Slave Coast, east of the British Gold Coast, between 0°30′ E. long. and 1°41′ E., the boundary towards the interior being somewhat indefinite. The area is estimated at 16,000 sq. m., and the pop. at 500,000. Togo, the largest native town (pop. 8000), is on Lake Togo; Little Popo is the capital, and Lome the chief port.

Toise, an old French linear measure, containing 6 French feet; it was equivalent to 1·949 French mètres, or to 6·395 English feet.

Tokat, a town of Sivas province, Asia Minor, 70 miles inland from the Black Sea. Pop. 10,000.

Tokay, a small Hungarian town on the Theiss, 130 miles NE. of Pesth by rail, with a pop. of 4479. It was destroyed by fire in 1890. In the neighbourhood several battles took place during the troubles of 1849; but the place is known solely for its famous wine, grown on the Hegyalja Mountains. Great care is bestowed on the proper assortment of the grapes (which are never gathered till fully ripe), and also on the preparation of the wine—of which some thirty-four sorts are reckoned; but all of these may be grouped into the two classes of sweet and dry. The wine is brownish yellow while new, changing to a greenish hue as it grows older. The average annual produce of the Tokay vineyards is over 2,000,000 gallons. Tokay wine enjoys an immense reputation. The *Ausbruch* is one of the finest kinds, but is surpassed by the *Essence*, regarded by many as the noblest of all wines, made from the juice that exudes from the grapes by the pressure of their own weight. Genuine Tokay is obtainable by wine-merchants only in small quantity (this is especially the case with the more valuable sort, the sweet or imperial Tokay), and is largely mixed with inferior wines to increase the amount. Large quantities of 'imitation' Tokay are made by French and German chemists, and sent to all parts of Europe, not excepting Hungary itself.

Token. For token money, see MONEY, Vol. VII. p. 270. In Scotland it was usual both in the Established Church and in seceding churches for the minister and elders to furnish communicants with tokens or small vouchers of brass or pewter, serving as passes permitting them to take their places at the communion table, whereupon the tokens were returned to the officiating elders. This system of metal tokens has now been generally superseded by cards.

Tōkyō, or TŌKEI ('Eastern Capital'), is the chief city of the Japanese empire. Until 1868, when the emperor removed his court thither from Kyōtō, it was known as Yedo ('Estuary Gate'). Originally the site of a small castle, it was chosen by Tokugawa Iyeyasu in 1590 as the seat of his power, and 80,000 of his warriors settled here. The *daimyos* (territorial lords) were also compelled to spend six months of the year in Yedo. By reason of its position at the mouth of the rivers which drain Musashi, the largest of the plains of Japan, it is well fitted to be a national centre. From it Japan was reduced to unity under the Tokugawa *Shôguns*, and the emperors, in resuming direct power on the fall of the Shôgunate in 1868, sought to carry on the traditions of centralisation by establishing the restoration government in Yedo. The city has gradually been enlarging seaward, as it takes possession of the growing delta of the river Sumida, on whose south bank it is situated. The lower portion of the city, which is flat and intersected by canals, stretches between the two parks of Ueno (north) and Shiba (south), famous for their shrines and as alternate burial-places of the Tokugawa Shôguns. Midway rises the castle, the central buildings of which were burned in the restoration troubles, now the site of the palace (1889), a fine structure in Japanese style, furnished *à l'Européenne*, and lit with electricity. Its double ring of high walls and broad moats is finely picturesque. In spring-time the city is gay with plum and cherry blossoms, the river-side avenue of Mukojima, 5 miles long, presenting a unique spectacle. The immense inclosures (*yashiki*) formerly inhabited by the nobles and their retainers are gradually disappearing, and handsome modern buildings in brick for the use of the various government departments are taking their place. Of the fifteen city divisions (*ku*) the northern, Hongo and Kanda, are mostly educational, and contain the buildings of the Imperial University, First Higher Middle School, Higher Normal School, Law School, &c. The student population is astonishingly large, and is an element of danger, as the lads are almost wholly without proper parental or other control. The seaward districts of Nihonbashi, Kyobashi, and Asakusa are industrial and commercial, while the government offices are located in Kojimachi *ku*. The plain but nicely finished buildings in which the first Japanese parliament met in 1890 were consumed by fire in 1891, but have since been rebuilt. There is an anchorage at Shinagawa, the southernmost suburb of the city, but Yokohama is the port of entry (17 miles off). The climate of Tōkyō is moist and unhealthy in summer, but is generally fine and healthy from September to the beginning of June. The winter nights are cold, and the keen winds of spring sweep the dust violently through the streets. The city is subject to disastrous fires; that of April 1892 burned 4000 houses in one morning. Tōkyō has two railway termini 5 miles apart—Shimbashi, connecting it with Yokohama and the south; Ueno, connecting

it with Nikko and the north. A suburban railway unites the two systems. *Jinrikishas*, small two-wheeled carriages drawn by men, are the chief means of conveyance; but tramcars and buses crowd the principal thoroughfares and connect the scattered districts. There is a foreign concession at Tsukiji, on the south bank of the Sumida, mostly inhabited by missionaries. The foreign population of Tōkyō is about 800, foreign employees and missionaries. Tōkyō resembles Paris in the overshadowing importance of its place in the national life; it is alive with new schemes and undertakings, and almost every phase of modern industrial civilisation is to be found within its vast area. Pop. (1890) 1,376,280; (1899) 1,440,121. See JAPAN.

Toland, JOHN, deistical writer, was born of Catholic parents near the village of Redcastle, County Londonderry, November 30, 1669. He entered the university of Glasgow in 1687, but removed to Edinburgh, where he abandoned the Roman Catholic faith and took his M.A. in 1690. At Leyden, where he spent two years, he studied theology under Spanheim. He resided for some time at Oxford, and in the Bodleian collected the materials of more than one of his later publications. In *Christianity not Mysterious* (1696) he expressly claimed to accept all the essentials of Christianity, but maintained that the value of religion could not lie in any unintelligible element, and that no part of the truth could be contrary to reason. He chose his title with evident reference to Locke's *Reasonableness of Christianity* (1695), and professed to have at heart the defence of revelation against deists and atheists. But the tendency of the work was obvious; it created a great sensation in the theological world, and led to several replies (by Payne and Stillingfleet amongst others). Prosecuted in Middlesex, Toland returned to Ireland, where his book was burned publicly by the common hangman, and Toland fled to London. In *Amyntor* (1699) and other works he fairly raised the question as to the comparative evidence for the canonical and apocryphal scriptures, with professed candour but unmistakably mischievous intent. A pamphlet entitled *Anglia Libera*, on the succession of the House of Brunswick, led to his being received with favour by the Princess Sophia when he was secretary to the ambassador at the court of Hanover; and from 1707 to 1710 he lived in various continental towns. His after life was that of a literary adventurer, and forms one of the most painful chapters in D'Israeli's *Calamities of Authors*. In *Nazarenus* (1720) he insisted, somewhat on the lines developed by Semler and the Tübingen school, that there were two distinctly opposed parties in the early Christian church—one Judaistic (which he identified with the Ebionites) and one Pauline or liberal. His *Pantheisticon* was an offensive parody of the Anglican liturgy. He resided from the year 1718 at Putney, where he died, March 11, 1722.

Besides the works named, and various defences, apologies, and pamphlets, he wrote a life of Milton (1698); an *Account of Prussia and Hanover* (1705); *Adeisidæmon* (1709); *Origines Judaicæ* (1709). See the books cited under the heading DEISM in this work; and for Toland's partial anticipation of Semler and Baur, see an article in the *Theological Review*, 1877. There is a life by Des Maizeaux prefixed to two vols. of Toland's posthumous works (1747, including a *History of the Druids*), and a monograph by Berthold, *John Toland und der Monismus der Gegenwart* (Heidelb. 1876).

Toledo, a famous city of Spain, capital of a province, and long the capital of the whole country, stands on the north bank of the Tagus, by which it is encompassed on three sides, 40 miles SSW. of Madrid by rail. It is situated on a number of hills, 2400 feet above sea-level; and the climate, excessively hot in summer, is bitterly cold in winter. The Tagus, surrounding the city on the east, south, and west, and flowing between high and rocky banks, leaves only one approach on the land side, which is defended by an inner and an outer wall, the former built by the Gothic king Wamba in the 7th century, the latter by Alfonso VI. in 1109, and both remarkable for the number and beauty of their towers and gates. Seen from a distance the city has a most imposing appearance; within it is gloomy, silent, inert, and its narrow streets are irregular, ill-paved, and steep. In the middle of the city rises the lofty, massive cathedral, surrounded by numerous churches and convents, mostly deserted. The cathedral, built in 1227–1493, on the site of a former mosque (consecrated to Christian uses in 1086, but pulled down to make way for the new church), is a large oblong edifice with semicircular apse, and belongs to the simplest, noblest style of Spanish-Gothic, with a few touches of the florid Gothic, classical, and Saracenic styles. The interior is more impressive than the exterior, which is blocked by other buildings on all sides save one. It was ransacked and plundered in 1621 and 1808, but it still contains some admirable stained glass, and the choir is a perfect museum of sculpture. The cathedral is 404 feet long and 204 feet wide, and has five naves; the tower is 329 feet high. Connected with the cathedral are an extraordinary number of chapels, of great interest, alike from their architectural beauty, their decorations, and their historical associations. The great square or Zocodover, thoroughly Moorish in its architectural character, is a fashionable promenade, and was long the site on which heretics were burned and bull-fights took place. Moorish architecture is conspicuous in some churches, and in two gateways. The Alcazar or old palace, the fortress commanded by the Cid, rebuilt as a palace in the time of Charles V. and subsequently, occupied the highest part of the city, but was burned down in 1887. The buildings of the town include a theological seminary, one or two old palaces, hospitals, what was once a great monastery, town-hall, &c. There are manufactures of church ornaments and vestments in gold, silver, and silk, and confections. The best Spanish is said to be spoken here. Toledan sword-blades, famous since old Roman times, are still made, but outside the city. Pop. (1887) 20,837.

Toledo, the *Toletum* of the Romans, is of very early origin. It was the capital of the Goths during their dominion; in 714 it fell into the possession of the Moors, who retained it till 1085, when it was permanently annexed to the crown of Castile as capital. In the days of its highest prosperity it is said to have contained 200,000 inhabitants. It was the headquarters of the Inquisition. The university, founded in 1498, is long since extinct. The whole place has now a dilapidated and broken-down appearance. For the area and pop. of the province, see SPAIN, Vol. IX. p. 598.

Toledo, capital of Lucas county, Ohio, on the Maumee River, 8 miles from the western extremity of Lake Erie (to which a channel 17 feet deep has been dredged), and 92 by rail W. of Cleveland. It has a fine harbour, is on the Miami and Erie Canal, and is connected with all parts of the country by thirteen railways. Besides an immense union depôt, it has grain elevators holding 5,000,000 bushels, and a great trade is done in flour and grain, as well as lumber, live-stock, hides, wool, iron, cotton, and tobacco. There are great wagon-works, foundries, manufactories of boilers, pumps, engines, farming implements, and furniture, and boat-yards and bridge-works. Toledo was settled in 1832, and incorporated in 1836. Pop. (1880) 50,137; (1890) 81,434.

Toledoth Jeshu (Heb., 'the generations of Jesus'), an apocryphal work in Hebrew purporting to be a history of Jesus; really a mediæval series of clumsy, fragmentary, ribald fictions and burlesques. There are two recensions, of one of which Wagenseil published a Latin translation in 1681. This one may probably contain an ancient element; the other, which Huldrich translated into Latin in 1705, is not older than the 14th or 15th century.

See Baring-Gould, *The Lost and Hostile Gospels* (1874); *Notes and Queries*, 6th series, vol. xi. (1885) p. 212.

Tolentino, an episcopal city of Central Italy, 10 miles SW. of Macerata. Pop. 4888.

Toleration is the liberty conceded, especially where a particular form of religion is established by law, to those of other religious beliefs to publicly teach and defend their theological and ecclesiastical opinions, and to worship whom and how they please, or not at all. But no permission is thereby given to violate the rights of others, or to infringe laws designed for the protection of decency, morality, and good order, or for the security of the governing power. In Britain there are still in force certain statutes imposing penalties on opinions and practices, once regarded as criminal because of their offensiveness to God, such as Blasphemy (q.v.); but these laws are seldom executed now, the opinion having become prevalent that, except when the religious feelings of the public are so wantonly outraged as to make the perpetrator a nuisance, theological error is best opposed by refuting it, and that when those accused of Heresy (q.v.) are men of piety and earnest conviction any degree of severity short of extirpation tends rather to diffuse than to suppress their tenets. The right of private judgment in matters of faith and worship is now more generally recognised in practice than it used to be, though even yet many resent the exercise by their neighbours who differ from them of the freedom which they claim for themselves. In a church claiming infallibility, and believing that salvation is unattainable beyond her pale, it is not only consistent, but to her more earnest members must seem a duty, to prevent by force the spread of what is accounted a fatal heresy; and, in fact, toleration has never been either professed or practised by the Church of Rome. The Reformers, as a whole, while claiming freedom for themselves, by no means accepted the principle of tolerating what they regarded as pernicious doctrines: a notable case to the contrary is Calvin's treatment of Servetus (q.v.). The peace of Westphalia (1648), which closed the fearful Thirty Years' War, secured a religious and civil freedom in Germany for Catholics, Lutherans, and Calvinists, but for no others. Even the English Puritans, though long oppressed themselves, were so blind to the right of others to differ from them that in their own brief day of power they eagerly repudiated, by word and deed, as a monstrous and impious error, the principle of a universal toleration. In the Westminster Assembly of Divines (1643–46) the Presbyterian members fought successfully against the proposal of the Independents that all sects should alike be tolerated. 'We hope,' wrote Baillie to his Presbyterian friends in Scotland, 'that God will assist us to demonstrate the wickedness of such a toleration.' George Gillespie's view was similar. We accordingly find in the 23d chapter of the *Westminster Confession* an assertion of the duty of the magistrate to promote the true religion, and to restrain and punish heterodoxy—a principle which, soon after the Restoration, was found to work very inconveniently for the Presbyterians themselves, the magistrate being then one who differed from them as to what the true religion was. The Independents, on the other hand, had learned the lesson of toleration in Holland—that nursery of liberty in modern Europe—whither they had fled from oppression in the reign of James I. It is, however, a mistake to suppose that they were the first to understand and practise the principles of religious freedom, for in the 16th century Zwingli and some of the Hungarian reformers disclaimed, by word and action alike, the notion that any man is entitled to assume, in his dealings with others, that his own interpretations of Scripture are true, and those of other men, if different, false and culpable.

The English sectaries who founded the American colonies, fleeing from religious intolerance, brought with them no larger toleration for others. In most New England states dissent was punished as heresy, though Roger Williams insisted that 'to punish a man for any matter of his conscience is persecution.' In Pennsylvania no man could hold office who did not acknowledge the deity of Christ; and in Maryland Quakers were fined and variously punished from 1659 onwards. To the keen discussions in Holland and England during the century which followed the Restoration; to the moderation or indifference which characterised the Protestant churches a hundred years ago; to the ever-increasing number and power of dissenters; to the enormous impulse given to the notion of personal rights by the French Revolution; and to that wider mental culture which enables men to see that diversity of mental gifts and acquirements naturally leads to diversity of opinion, it is that we must ascribe the tolerant spirit now generally diffused, especially in England and the United States. Not only is the *right* of free thought and discussion now generally recognised, but its *necessity* to the well-being of mankind is asserted by eminent thinkers. And in most civilised countries, though churches may be limited in their privileges, private freedom is accorded to all religious belief: Russia is of great Christian nations the most intolerant.

See Jeremy Taylor's *Liberty of Prophesying;* Milton's *Areopagitica*, his *Treatise of Civil Power in Ecclesiastical Causes*, and his treatise *Of True Religion, Heresy, Schism, Toleration, &c.;* John Owen's *Indulgence and Toleration Considered;* Barclay's *Apology for the Quakers;* Locke's *Letters concerning Toleration;* Paley's *Moral Philosophy;* Sydney Smith's *Letter to the Electors on the Catholic Question;* Martineau's *Rationale of Religious Enquiry;* Guizot's *History of Civilisation in Europe;* Buckle's *History of Civilisation;* Mill *On Liberty;* Lecky, *Rise of Rationalism* and *History of European Morals;* Bancroft, *History of the United States;* the church histories; and in this work the articles Catholic Emancipation, Jews, Persecution, works cited at Friends, &c.; also Sidney (Algernon).

The Act of Toleration was an act passed after the English Revolution of 1689, with the hearty support of William III. It repealed the persecuting acts of Charles II.'s reign against conventicles, &c., and practically gave religious toleration to Protestant dissenters and Quakers, but expressly excluded Roman Catholics or anti-Trinitarians.

Toll, an old English word used for tax or tribute ('to whom tol tol;' Wyclif's Bible, Rom. xiii. 7), especially for long (like the German *Zoll*) applied to customs duties, but ultimately almost wholly restricted to money paid for the maintenance of roads by persons using them, and collected from travellers by collectors at toll-gates or toll-bars. Road-tolls were granted by Edward III., and the turnpike soon spread itself over all England, superseding 'statute-labour' in Scotland in 1750. The Rebecca Riots (q.v.) of 1843 were but one instance of the unpopularity of the impost; but in 1871 there were in most parts of the country toll-houses

every six or eight miles, and about 5000 persons employed as toll-collectors (not including their families). A board affixed to the toll-house indicated the varying rates of dues exacted for an ass, a score of sheep, a riding horse, a cart, a one-horse gig, a carriage drawn by two horses, &c. Ireland first threw off this form of the burden, an act of 1857 abolishing the last in the island. In England twenty-seven toll-bars near London were abolished, and eighty-one on the north side of London in 1864, sixty-one on the south side in 1865. Others followed (in Scotland, in 1883, under the Roads and Bridges Act, 1878), but it was not till 1889 that the system in Great Britain was finally superseded by the mode of management now in force, for which see ROADS. Bridge-tolls were all abolished in London in 1878–79, but they still survive in some places, and pier-tolls are common.

Tollens, HENDRIK, a Dutch poet. See HOLLAND, Vol. V. p. 745.

Tolosa, a town in the northern Spanish province of Guipuzcoa, 15 miles S. of the seaport of San Sebastian by rail. Pop. 7239.—*Tolosa* is also the ancient name of Toulouse.

Tolstoi, or TOLSTOY, a noble Russian family, several of whose members have become eminent in diplomacy, war, and literature. Count Peter (1645–1729) was long a trusted agent of Peter the Great; Count Peter Alexandrovitch (1761–1844), one of Suvorof's generals, was under Nicholas I. head of a government department; Count Alexei Constantinovitch (1818–75) was one of the foremost of modern Russian dramatists, a lyrical poet and novelist (his historical novel, *Prince Serebrenni*, was translated into English in 1874); Count Dmitry Andreievitch (1823–89), reactionary minister of Education, was a champion of Russian orthodoxy and the Russifier of the Poles, whose *Romanism in Russia* was translated in 1874. But far better known outside of Russia is

COUNT LEO NIKOLAIEVITCH, poet, novelist, social reformer, and religious mystic, born 28th August (o.s.) 1828, at Yásnaya Poliána in the government of Tula. He was educated privately at Moscow, and on the family estate till 1843–46, when he studied at Kazan University; in 1851 he joined the army of the Caucasus on the Terek, was attached to the staff of Prince Gortschakoff in Turkey in the first stage of the Crimean war, and was at the storming of Sebastopol by the allies in 1855. He now retired from the army, and, already famous as a poet and novelist, spent a short time in the most brilliant literary and social circles of St Petersburg. He then travelled in Germany and Italy; in 1862 he married, and since then has lived on his estates near Moscow amongst the peasantry.

It was during his residence in the Caucasus that he wrote *Childhood, Boyhood, and Youth*, *Memoirs of Prince Nekludoff*, and *The Cossacks*. After the Crimean war he wrote three sketches of Sebastopol; during his foreign sojourn, *The Snow Storm*, and the *Two Hussars;* next came *Family Happiness*, *The Three Deaths*, and *Polikushka*. The first of his two great works, *War and Peace* (1865–68), gives a marvellously vivid picture of the Napoleonic campaigns against Russia and the national defence; like many Russian novels, it is devoid of a regular novelistic plot, and is a kind of chronicle of two families and their friends, showing how their fates and characters were moulded by the events of that terrible time. The other great work, *Anna Karenina* (1875–78), is a melancholy tale of an ill-fated marriage, in which the inability to recognise the prosaic responsibilities of life leads to the suicide of the unhappy wife. It is, as Mr Arnold said, less a work of art than a piece of life; but what it loses in art it gains in reality. 'There is an abundant and admirable exhibition of knowledge of human nature, penetrating insight, fearless sincerity, wit, sarcasm, eloquence, style.'

Soon after this he intimated to the consternation of his friends that he had finally resolved to renounce the career of poet and artist to devote himself to studying the pressing problems of life, remedying its grievances, and becoming the 'friend of the unfriended poor.' Since that time he has not ceased to write, nor even to write novels, but all his work is written with directly didactic aim. *Ivan Ilyitch*, *What People Live by*, *Where Love is there God is also*, *Two Pilgrims*, *The Dominion of Darkness*, *The Christianity of Christ*, *What I Believe*, and *Life*—all insist on a mode of thought and ideal of life in which revolutionary discontent and religious confidence, Puritanism and Quietism, hyper-Christian self-devotion and an almost Buddhist resignation, deep insight and morbid asceticism are strangely combined and commended by the author's literary power, transparent sincerity, and self-denying tenderness for all the weary, heavy-laden, and oppressed. True religion (not dogmatic orthodoxy) is for him the most valuable element in life, and, though rare in the cultivated, is common if not ineradicable in the working poor, in the people. His conception of Christ's Christianity is summed up in six canons: Do not war; do not judge; do not commit fornication; do not swear; do not give way to anger; do not oppose with force the evil-doer—this last carried to the point of not interfering by force to prevent a murder. The *Kreutzer Sonata* (1890) finds the trail of the serpent—carnal passion and baseness—not merely in most existing social conditions, but in art as now practised, and even in what for others are the sanctities of family life. Turgenief and Tolstoi, with many points of sympathy, never could agree, and had more than once a bitter quarrel; but on his deathbed Turgenief sent a loving message to 'Leo Nikolaievitch' beseeching him to return to literature. Tolstoi would have wholly dispossessed himself of his property to live as a peasant; but his wife refused to see her children exposed to hardship, and Tolstoi made over his estates to her and them. Of his family, only two daughters (out of eight children) sympathise with him. He lives as poorly as a peasant, labours at mowing or sawing wood for any neighbour who asks him, and in his wife's house lives as a guest. In time of famine he is indefatigably self-denying in ministering to the sufferers. Recent works are *The Kingdom of God is Within You* (1893), *Master and Man* (1894), *Patriotism and Christianity* (1896), *Henry George's System* (1897), *What is Art?* (1898), and *The Christian Teaching* (1899)—the latter published simultaneously in Russian, German, French, and English newspapers. The keynote of his revolutionary doctrine of art is, that only that art is good which moves the masses, and to good ends; what is written for the select can only be bad art.

See Matthew Arnold, *Essays in Criticism* (2d series, 1888); De Vogüé, *Le Roman Russe* (1888); C. E. Turner, *Count Tolstoi* (1888); Loewenfeld, *Leo Tolstoi* (Berlin, 1892); C. A. Behrs, *Recollections of Tolstoy* (trans. 1893); G. H. Perris, *Leo Tolstoi, the Grand Mujik* (1898).

Toltecs. See MEXICO.

Tolu. See BALSAM.

Toluol, or TOLUENE, another name for Methyl Benzene (see AROMATIC SERIES, BENZENE), a colourless liquid with the odour of benzene, which dissolves sulphur, iodine, and many resins. It is obtained from the dry distillation of tolu or other resin, by the action of potash on benzylic alcohol, by heating toluic acid with lime, and as a coal-tar product. From it Saccharin (q.v.) may be obtained. Toluidin is a derivative of Toluol.

Tomahawk, a light war-hatchet of the North American Indians. The early ones were made of stone or of deer-horn put through a handle of wood, or fastened to the handle by sinews or cords of skin; European traders supplied hatchets of steel. The blunt side of the head was sometimes made hollow, for a tobacco-pipe, a handle of ash, with the pith removed, being the stem. Tomahawks might be either used in close combat or thrown so that the edge would strike the object aimed at. The usage of the Indians supplies the phrases to bury the hatchet and to dig it up, as equivalents for to make peace or to declare war.

Tomato, or LOVE-APPLE (*Lycopersicum esculentum*), a plant of the natural order Solanaceæ, so named by Tournefort, but subsequently combined by Linnæus with the genus Solanum, now, however, recognised as a distinct genus under the name of the earlier botanist. It is distinguished from Solanum by the stamens having the anthers connected by a thin membrane, and by their cells opening in longitudinal slits on the sides, not in pores at the apex as in that genus. The fruit is fleshy, usually red or yellow, divided into two, three, or more cells containing numerous seeds imbedded in pulp. The tomato is one of a genus of several species, all natives of South America, chiefly on the Peruvian side. It is the only species in cultivation in Europe, into which it was brought by the Spaniards in 1583. In the warmer countries of Europe, the United States, and other countries in which the summer is warm and prolonged, it has long been cultivated for the excellent qualities of the fruit as an article of diet. Although belonging to a natural order of plants usually regarded with suspicion on account of the powerfully poisonous

Large Early Red Tomato:
a, fruit of do.; *b*, fruit of common tomato.

properties of many of the species comprised in it, it is now recognised as one of the most important and valuable of vegetables grown for human food. Though it was introduced into Britain as early as 1596, the consumption of its fruit there is still small as compared with some other European countries and America, but it has increased immensely since 1880. The annual supply produced in Britain is quite inadequate to meet the demand, which is yearly increasing as the agreeable qualities of the fruit become more widely known; consequently enormous quantities of it are imported, packed dry and in tins, the latter being chiefly used in making soups and sauces. The imported fruit, having to be packed in an imperfectly ripe state in order to reach its destination in safety, is inferior to that grown in Britain in colour, flavour, and texture; the latter, therefore, commands the highest price in the market. On this account the culture of the tomato has of late years developed into a distinct horticultural industry, like grape-growing and mushroom-growing. Very extensive establishments in glass have been erected at Worthing in Sussex and at other places in England and in Scotland exclusively for its culture, which proves a remunerative enterprise. The plant is annual in duration, and too tender to be grown successfully in the open air in Britain, except it is reared in heat and grown in pots to the flowering stage under glass before the beginning of June, the earliest period at which it may be safely turned out of doors. Even then it must be planted against a wall with a warm exposure and well sheltered. The seeds are sown in February and March in a temperature of 55° to 65°. An open friable soil is essential, and the use of potash as a manure is hardly less so. The details of management cannot be entered into here. Like its near relative the potato, the tomato is subject to attacks of phytophthora—the potato-disease fungus, and the fruit is liable to a disease also of fungus origin, which causes considerable loss to inexperienced growers, but rarely attack the plants of those who understand their treatment under glass.

The fruit is cooked in a great variety of ways: broiled or fried by itself, or with meat or other accompaniments; made into soups and sauces; sliced raw, it is an excellent ingredient in salads, and eaten with vinegar and pepper and salt uncooked it is perhaps as wholesome and refreshing as in any other way. Its use in any way as food is considered beneficial in affections of the liver, indigestion, and diarrhœa. The word tomato is derived from the Spanish American name *tamate*, and the English name Love-apple has arisen from its supposed aphrodisiac properties.

Tomb (Gr. *tymbos*), a monument erected over a grave, in order to mark the resting-place, and preserve the memory, of the deceased. In early ages, and among eastern nations, it sometimes became the practice to place the remains of the dead in excavated sepulchres, whose interior was often decorated with painting or otherwise. Where the usage was to burn the dead their bones and ashes were placed in urns in these receptacles. Some of the most remarkable rock-tombs were those of Egypt. The rock-tombs of Persia and Lycia have imposing architectural façades. See also CATACOMBS, ETRURIA, PETRA.

Tombs in more modern times have generally been mounds or masses of building raised over the remains of the dead. In the Homeric poems heaps or cairns of stones are placed as honorary memorials above the graves of departed heroes. The tumulus of rude ages (see BARROW, CAIRN) is found over the greater part of northern Europe, and is probably older than the subterranean tomb. The Pyramids (q.v.) were the sepulchres of the Egyptian monarchs from the 4th to the 12th dynasty. The tombs of Greece, and still more those of the Greek colonies in Asia Minor, were sometimes pillars, or upright stone tablets, sometimes small buildings in the form of temples; the most celebrated was the Mausoleum (q.v.). The Roman tombs were not unfrequently important architectural structures, varying in form, but oftenest consisting of a circular tower resting on a square basement; familiar examples being the tomb of Cæcilia Metella (see ROMAN ARCHITECTURE), and the yet larger and more solid tomb of Hadrian, on the banks of the Tiber, best known as the castle of S. Angelo, which is about 220 feet in height, and of immense solidity. The tombs were generally erected outside the towns, and along the principal roads leading into the country, as in the Via Appia at Rome, and the Street of Tombs at Pompeii. A form of excavated tomb, without external architec

ture, called Columbarium (q.v.), was also in use in Rome, whose walls were pierced with cells to receive cinerary urns. The prevalent circular tomb became in the later period of the Roman empire polygonal. In many parts of Italy, and in such Spanish-American towns as Lima and Quito, the cemeteries contain rows of niches rising above one another in terraces, honeycomb-like, and each holding a coffin, which rests there so long as the heirs pay the rent.

In the earlier centuries of Christianity the burial of the dead in churches was prohibited. The first step which led to its adoption was the custom of erecting churches over the graves of martyrs; then followed the permission to kings and emperors to be buried in the church porch. The most important tombs of the middle ages are generally within churches or cloisters. The earlier examples consist of a simple stone coffin, or sarcophagus, often with a low gabled lid and a sculptured cross. An altar-tomb, or tomb in the form of a table, followed; and in the 13th century a species of tomb was introduced, consisting of a sarcophagus, on which rests a recumbent figure of the deceased, the whole being surmounted by a canopy, often of exquisite symmetry and richness (see illustration at CANOPY). The tombs of the Scaligers at Verona, with their beautiful wrought-iron railing, are famous. In the renaissance period of art the tombs became more and more complex. The sarcophagus was disguised, or made the least important part of the monument; the representation of the deceased was confined to a medallion likeness, and the most prominent part of the tomb was composed of sculptured upholstery, and groups of symbolical and eventually mythological figures. In some of the 16th-century examples, as Michaelangelo's tombs of Giuliano and Lorenzo di Medici, at Florence, the inappropriateness of the design is partly redeemed by the beauty of the figures; but in the succeeding centuries the vicious taste of these monuments rapidly increased, till it culminated in some of the hideous tombs that disfigure Westminster Abbey and St Paul's. See also the articles BURIAL, CEMETERY, NECROPOLIS, and others cited at MONUMENTS.

Tombac, a name given to an alloy of copper and zinc like Prince's Metal (q.v.), or to an alloy of copper and arsenic.

Tombigbee. See ALABAMA.

Tomi. See OVID.

Tompkins, DANIEL D. (1774–1825), was vice-president of the United States from 1817 to 1824, but is most noteworthy for his energetic organisation of the militia of New York state—of which he was governor from 1807 to 1817—during the war with Great Britain.

Tomsk, a town of western Siberia, on the Tom, a tributary of the Obi, 2809 miles E. of St Petersburg. Situated on the great trade-route from Tiumen to Irkutsk, and near the main line of the Siberian railway, it has long been the seat of an important transit trade. Leather and carriages are manufactured; and a university was established in 1888 (see SIBERIA, p. 429). Great part of the town was burned in 1890. Pop. 45,000.—The *government* of Tomsk, extending to the Chinese frontier, has an area of 331,159 sq. m.—more than 2½ times the size of Great Britain and Ireland. Pop. (1895) 1,432,000.

Tom-tit. See TIT.

Ton, the same word as Tun (q.v.), denotes a weight of 20 hundred-weight (*cwt.*). In Britain the hundred-weight contains 112 lb., so that the ton contains 2240 lb. In the United States the hundred-weight is usually reckoned at 100 lb., and the ton (the 'short' ton) at 2000 lb. Ton is also a measure of capacity, varying with the substance measured—timber, wheat, gravel, lime, coke, &c. For the ton used in measuring ships, see TONNAGE.

Tonalite, an igneous rock having a granitic structure, and composed essentially of plagioclase, biolite, and quartzite. Hence it is simply a quartz-mica-diorite.

Tonawanda, a town of New York, on the Niagara River and Erie Canal, 8 miles N. of Buffalo by rail. It contains several mills and other manufactories. Pop. (1890) 7145.

Tonbridge. See TUNBRIDGE.

Tone, in Music. See INTERVAL. For the Gregorian Tones, see PLAIN-SONG.

Tone, THEOBALD WOLFE, Irish patriot, was born the son of a coach-maker in Dublin, 20th June 1763. He had his education at Trinity College, Dublin, entered the Middle Temple, and was called to the bar early in 1789. But he soon plunged into political intrigues, acted some time as secretary of the Catholic Committee, and had a large share in the organisation of the United Irishmen. His active mind was impatient of constitutional methods, and from an early period of his career he dreamt of foreign invasion as the remedy. Naturally he found it necessary to take refuge, first in America, next in France. He laboured incessantly to induce the Republican government to take up the scheme of an invasion of Ireland, and held a command in the unlucky expedition under Hoche. In 1798 he again embarked in a small French squadron, which after a fierce fight was captured. Tone was taken to Dublin, tried, and condemned to be hanged as a traitor. He cut his throat in prison, 19th November 1798. His autobiography, edited by his son, an officer in Napoleon's army, and afterwards in the United States service, appeared at Washington in 1826. It is an interesting revelation of a mind of remarkable activity, and a character ruined by inordinate self-esteem and reckless unscrupulousness.

See his *Autobiography* (new ed. by Barry O'Brien, 1892); the Life in Dr Madden's *United Irishmen* (3d series, vol. i. 1846); and, as an antidote, two papers by the Duke of Argyll in the *Nineteenth Century* for May and June 1890.

Tonga. See FRIENDLY ISLANDS.—Tonga Bay is a small inlet on the east coast of Africa, bounded on the N. by Cape Delgado.—Tongaland is a British district on the east coast of South Africa, north of Zululand. Area, 1170 sq. m.; pop. 100,000.

Tongariro. See NEW ZEALAND, p. 486.

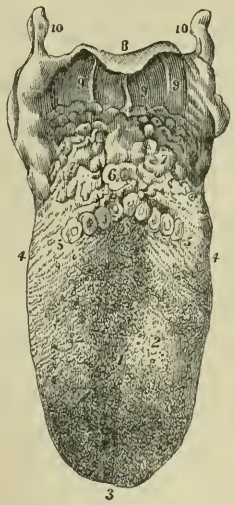
Tongking, TONQUIN, or TONKIN, since 1884 a French possession, is the north-east portion of the Indo-Chinese peninsula (see map at BURMA), bordering on China. The name has been used for various areas in this region. The various usages of the word, its physical geography, ethnography, and history are described at ANNAM, of which country it is naturally part. As is there mentioned, the main feature of the country is the Song-coi or Red River (variously spelt Song-koi, Sang-koi, &c.), coming from Yunnan, and traversing the whole of Tonquin lengthwise. The area is 34,700 sq. m.; the pop. was estimated in 1891 at 9,000,000. The capital is Hanoi (q.v.). The chief produce is rice, silk, sugar, pepper, oil, cotton, tobacco, and fruits, with some copper and iron; and companies are now working coal and antimony mines at one or two places on the coast, especially near the chief port of Haiphong. The imports in 1890–98 had an annual value of 30,000,000 francs (one-third only from France), the exports of 14,000,000 francs (only a small fraction to France). The French scheme of tapping the resources of Yunnan by means of the Song-coi has proved impracticable, the navigation of the upper course being very difficult

and at times impossible. The unpopularity of the Tongking expedition, and the tediousness of the war it led to, brought about the fall of Jules Ferry (q.v.), nicknamed 'le Tonkinais.'

See C. R. Norman, *Tonkin; or, France in the Far East* (1884); J. G. Scott, *France and Tongking* (1885).

Tongres, a very ancient episcopal city of Belgium, in the province of Limburg, 12 miles NW. of Liége. The church of Notre Dame was built in 1240, but its cloister dates from the 10th century. There is a mineral spring in the vicinity, mentioned by Pliny. Pop. 8763.

Tongue, a symmetrical, muscular organ, extending from the hyoid bone upwards and forwards to the lips in front, and occupying the buccal cavity. The superior surface, borders, and anterior third of the inferior surface are free; elsewhere it is attached to adjacent parts by the investing mucous membrane and subjacent structures. At certain points this membrane forms distinct folds, containing fibrous or muscular tissue, which act to a certain extent as ligaments to the tongue. The most considerable of these folds is termed the *frænum* (or bridle) of the tongue, and connects its anterior free extremity with the lower jaw. It acts as a strong ligament, and limits the backward movement of the tip of the tongue. In very rare cases this ligament extends abnormally to the tip, so as to interfere with speech and mastication, and the child is said to be 'tongue-tied;' recourse must be then had to division of the frænum, popularly known as 'cutting the tongue.' Other folds of mucous membrane pass from the base of the tongue to the epiglottis; while from the sides of the base, passing to the soft palate, are seen two folds on either side, the 'pillars of the fauces' (see PALATE). The superior surface of the tongue is divided into two symmetrical lateral parts by a median longitudinal furrow, commencing at the tip, and extending back about two-thirds of the tongue's length. The various kinds of papillæ on their surface are described in the article TASTE. At the back of the surface, just behind the circumvallate papillæ, are large mucous glands, extending into long and capacious canals, and helping to secrete the fluid that moistens the tongue. On the inferior surface the longitudinal furrow, which extends from the tip to the frænum, is deeper than on the upper surface; on each side of it veins are seen running forwards; and immediately beneath the tip is a cluster of mucous glands, known as the glands of Nuck (their discoverer in 1690). The posterior extremity, or base, is flattened and extended laterally before it is inserted into the hyoid bone (known also as the lingual or tongue bone), which, with certain ligaments, must be regarded as the basis or framework of the tongue. The muscles of the tongue are usually divided into two groups—viz. the extrinsic muscles, which attach the tongue to certain fixed points external to it, and move it on them; and the intrinsic muscles, which pass from one part of the tongue to another, constitute its chief bulk, and move it on itself. These intrinsic muscular fibres run vertically, transversely, and longitudinally, and are so interlaced as mutually to support one another, and to act with the greatest advantage. By the action of the various muscles, the upper surface of the tongue may be made concave or convex, or may be pressed against the roof of the mouth; the tip may be protruded straight out or laterally, upwards and downwards, and into any recess. The organ is freely supplied with blood, mainly by the lingual artery, which is given off by the external carotid. With regard to the nerves, the glosso-pharyngeal and certain branches of the third division of the fifth nerve are concerned in the special sense of taste; other branches of the fifth nerve are concerned in ordinary sensation, while the hypoglossal nerve on each side is the motor nerve of the tongue.



Upper Surface of Tongue: 1, mesial line; 2, 2, lateral parts; 3, tip; 4, 4, sides or edges; 5, 5, V-shaped mass of circumvallate papillæ; 6, foramen cœcum; 7, mucous glands; 8, epiglottis; 9,9,9, fræna epiglottidis; 10, 10, greater horns of hyoid bone. (From Sœmmering.)

The tongue in mammals does not differ very materially from that of man; but in general there is a close coincidence both in size and form between this organ and the lower jaw. In the rodents the tongue has a wedge-like shape. In the giraffe and the ant-eater the tongue is much prolonged, being an important prehensile organ in the former, while in the latter it is driven into ant-hills, and the victims are secured by its viscid secretion. In the feline races the conical papillæ are converted into recurved spines of great size and strength, which the animal uses in scraping bones and in combing its fur. Except in mammals, the tongue is probably not an organ of taste. The Gasteropoda are provided with a very singular apparatus known as the tongue, and consisting generally of a thin membrane, long and narrow, and rolled, except at its anterior extremity, into a tube; this membrane is covered on its upper surface with transverse rows of minute teeth, or more commonly with plates having tooth-like siliceous projections. The Articulata do not present anything like a true tongue, although in insects a certain oval appendage is described as a *lingua*.

The functions of the tongue are gustation, prehension (in man and monkeys this function is supplied by the hand), mastication, insalivation, deglutition, and speech; to which may be added spitting and whistling, and in the case of the Gasteropoda the trituration of the food.

In its medical relations the tongue is of great importance as an index to the condition of the system, and particularly of the digestive organs; its appearance, whether firm or flabby, moist or dry, clean, furred, or unduly red and bare, is a valuable guide both as to the diagnosis and treatment of disease.

Amongst the diseases of the tongue may be mentioned *Inflammation* or *Glossitis*. The most marked characteristics of this affection are great swelling, tenderness, and difficulty in speaking and swallowing. It rarely occurs as an idiopathic or spontaneous affection, but often used to accompany severe salivation. It must be treated by purgatives and low diet, and by gargling, as in ordinary salivation (see SALIVA). Incisions are sometimes useful, both to relieve tension, and by the depletion that ensues. Abscess in the tongue is also occasionally met with.

Hypertrophy, or persistent enlargement of the tongue, sometimes seems to result from an imperfectly cured inflammation, but is probably in most cases congenital, although perhaps not noticed for a year or two. It sometimes attains an enormous size, but can generally be relieved by operation, at least in its earlier stages. A good deal of attention has been given during recent years to a condition called

leucoplakia, consisting in whitish spots or patches on the surface of the tongue, very chronic in their course, often traceable to some irritation, particularly smoking, and especially important because they not infrequently become the seat of cancer. One of the most common forms of disease of the tongue is *ulceration*, which may arise (1) from the irritation of a decayed tooth with a sharp jagged edge; or (2) from constitutional syphilis; or (3) from a disordered condition of the digestive organs. In the first case the tooth or its edge must be removed; in the second iodide of potassium with sarsaparilla should be tried; and in the third the complaint generally yields to regulation of the diet and of the digestive organs. *Cancer* is by far the most common tumour met with in the tongue, and is nearly always of the epithelial variety. It is frequently connected with some cause of irritation—e.g. from a broken tooth, or from excessive smoking—and is very much more common in men than in women. It is in general a rapidly fatal form of cancer; and operations for its removal, always serious, are less often followed by immunity than in some other organs. See Butlin, *Diseases of the Tongue* (1885).

Tonic, in Music. See KEY.

Tonics are medicines which, in cases of want of *tone* in the system, are employed to restore its strength and vigour. Tonics, to a certain degree, are stimulants; but while the latter produce a rapid but transitory excitement, the former slowly induce a certain degree of excitement, and the effect is permanent. Most tonics, in which category we must place the shower-bath, cold sea-bathing, open-air exercise, friction, &c., as well as drugs, act primarily through the nervous system, and secondarily produce their effects upon the system at large. It is of course of the greatest importance to ascertain to what defect in the system the loss of tone is due; whether to poorness of blood, to weakness of the heart, to defective digestion or excretion, or to enfeeblement of the nervous system generally. Otherwise the measures employed, while suitable in one of these conditions, may be very harmful if used in another. Amongst the chief medicines of this class are the dilute hydrochloric, nitric, nitro-hydrochloric, and phosphoric acids, various salts of iron, silver, and zinc, the various kinds of cinchona bark, with their alkaloids and their salts, cusparia, calumba, cascarilla, chiretta, gentian, quassia, and taraxacum, and generally most vegetable bitters. Although nux vomica and its alkaloid strychnine are placed by writers on Materia Medica amongst the 'special stimulants,' when given in very small doses they have a well-marked tonic action; and there is probably no tonic medicine of more general utility than the *Syrup of Phosphates of Iron, Quinine, and Strychnine* (Easton's Syrup), a non-officinal but widely-used preparation, of which every drachm (the ordinary dose) contains $\frac{1}{32}$ of a grain of strychnine.

Tonic Sol-fa. See SOL-FA SYSTEM.

Tonka Bean, the seed of *Dipteryx odorata*, a large tree, of the natural order Leguminosæ, suborder Papilionaceæ, a native of Guiana, having pinnated leaves and axillary racemes of purplish flowers. The fruit is an oblong, dry, fibrous pod, containing a single seed, which has a strong, agreeable odour, owing to the Coumarin (q.v.) which it contains, and which is sometimes found crystallised between the cotyledons. Tonka beans are used for flavouring snuff, and are put amongst clothes to preserve them from insects, and to communicate an agreeable odour. They are also, by a natural confusion, often called Tonquin Beans.

Tonkin. See TONGKING.

Tonnage, in regard to ships, is a measure both of cubical capacity and of dead-weight carrying capability. The term, used by itself, may have reference severally to 'builders' old measurement' tonnage (B.O.M.), 'register' tonnage, 'displacement' tonnage, 'freight' tonnage, &c., each of which expressions is more or less current in shipping circles. From very early times in the history of shipping a scale of one sort or other must have been employed to determine the relative capacity or carrying power of different vessels, and in point of fact the term 'tonnage' in this connection can be traced back for at least 500 years. In Britain the first act of parliament dealing with the subject was passed in 1422, a second was introduced in 1694, and a third in 1720, but the application of these was limited to particular classes of ships, or those employed in particular trades.

The first legal system of measurement having general application to all classes of merchant-ships was introduced in 1773, and is known as 'builders' old measurement.' Long before its legal enforcement, however, it, or a similar rule, had become the established practice of British shipbuilders, although not applied in an exactly uniform manner by different builders. Shortly stated, the rule was to multiply the length (minus three-fifths of the breadth) by the breadth, the product by half the breadth, and to divide by 94, the quotient expressing the tonnage. During the long period prior to the 19th century, when naval architecture made little progress, and types of ships and methods of construction were almost stereotyped, this system seems to have quite answered its original purpose—i.e. that of roughly expressing the 'dead-weight' carrying power of ships. But with the growth of shipping, and with the legal assessment of dues according to the tonnage as computed by this system, various methods of evasion were resorted to, the effects of which were most hurtful to true progress in ship architecture. The rule only concerned itself with length and breadth, and took no account of actual form or of depth, but assumed the depth to be equal to half the breadth. Builders had simply to increase the depth, leaving the length and breadth unchanged, or to make the form 'fuller,' in order to increase the carrying power without in any way increasing the legal and taxable tonnage. Ships were in consequence built with little beam and of such excessive depth as to render them unsafe and unseaworthy. The inadequacy and perniciousness of this system of measurement were only slowly recognised, and it remained in force until 1836, when a 'new measurement' law was substituted. For purposes of convenience, however, it continued to be used by builders in estimates as to cost and comparison of shipping, and even yet it is sometimes to be met with in builders' statements.

The 'new measurement' gave place in 1854 to 'register' tonnage, a system resembling it in principle, but much more perfect in its details, and which, with minor modifications, is still in force as the legal basis of measurement upon which dock, harbour, light, and other dues are assessed. It determines, in an accurate and easy manner, the entire internal capacity in cubic feet of a ship below the 'tonnage deck.' At suitably placed and equi-distant stations throughout the length of ship measurements are taken of the vertical transverse area of the hold, and these areas are used, in conjunction with the length of ship, in obtaining the volume of hold space. If a vessel's hull is continued unbroken to support a deck above the tonnage-deck, the volume of the space between the deck is separately estimated, and all closed-in spaces above the upper deck, such as poop, forecastle,

deck-houses, &c., intended for accommodation or stowage, are also calculated. The sum of all these volumes in cubic feet, divided by 100, gives the 'gross register' tonnage. A 'register' ton, therefore, is simply 100 cubic feet of space, and has only very indirect relation to a 'dead-weight' ton of 20 cwt. avoirdupois. What is known as 'nett register' tonnage—and actually forms the tonnage inscribed in the register of British shipping—is the figure remaining after certain deductions are made from the gross. It is intended to represent the space actually available in a ship for remunerative service, such as the stowage of cargo or the accommodation of passengers. In sailing-vessels the deduction is very small indeed, representing the space occupied by the crew, and usually only from 4 to 5 per cent. of the gross. In steamers the case is very different, for not only the crew-space, but that occupied by the engines, boilers, coals, &c. is deducted. Details as to the method of computing these deductions cannot be given here, but it may be stated generally that for the majority of ocean-going steamers the nett tonnage is reduced from the gross by as much as about 35 per cent. The question of deductions has all along presented many difficulties and anomalies, and in some cases the original law has had to be amended to obviate these. On the whole, however, the principle on which the present system of tonnage measurement is based has served the purpose admirably—certainly in a way much superior to any previous system—and during the years it has been in vogue comparatively few changes have had to be made, while, on the other hand, it has been adopted by all the principal maritime nations and by various international commissions. Alternative systems of tonnage measurement have been advocated from time to time when existing inequalities have been found to press specially hard, but none have found entire favour. One is the substitution of a dead-weight basis of measurement, on the grounds that internal capacity in the present conditions of the shipping trade is not the fair measure of the possible earnings of ships under most circumstances, while dead-weight capability is, and that such a mode of measurement would obviate all disputes and difficulties as to deductions and allowances. Both this proposal and a somewhat similar one, based on a vessel's 'displacement'—i.e. the total weight of a ship in tons when immersed to her maximum draught or load-line—have the great disadvantage of necessitating the fixing of an equitable maximum load-line for the various classes of vessels, and for the vessels of the several maritime nations. The fixing of a universal load-line in the case of cargo-vessels is a problem fraught with almost insuperable difficulty, although a partial solution has been attained in connection with certain types of British merchant-ships.

'Displacement' tonnage is by general consent regarded as the fairest measure for the tonnage of naval ships, since they are designed to carry certain maximum weights and to float at certain load-lines which are fixed with reference to the character of service. It has for many years been the official tonnage for the warships of France and other European nations, and since 1872—prior to which date the B.O.M. rule was the only one employed—the tonnage of British naval ships has been based on the displacement principle. The United States navy has also adopted displacement tonnage; in fact, it is all but universally employed.

'Freight' tonnage, a system of measurement commonly employed in connection with stowage by merchants and shipowners, although it has no legal authority, is simply a measure of cubical capacity. A freight ton, or 'unit of measurement cargo,' simply means 40 cubic feet of space available for cargo, and is therefore two-fifths of a register ton. It is a purely arbitrary measure, based on the assumption that 40 cubic feet are required to stow a ton weight, but for some kinds of cargo of a lighter nature 45 and even 50 cubic feet form the unit of measurement.

In connection with yachts tonnage is measured by special rules for the purpose of regulating time allowances in racing. These rules are numerous and varied almost as the yacht clubs and associations employing them, but the rule which has hitherto been most generally adopted in Britain is known as the 'Thames Rule,' and is simply a slight modification from the B.O.M. tonnage.

Tonnage and Poundage, certain duties on wine and other merchandise, which began to be levied in England in the reign of Edward II. They were at first granted to the crown by the vote of parliament for a limited number of years, and renewed on their expiry. The object of these imposts was said to be that the king might have ready money in case of a sudden emergency demanding it for the defence of the realm and the guarding of the sea. Originally fluctuating in amount, tonnage (more correctly *tunnage*) and poundage came to be fixed at 3s. on every tun of wine, and 5 per cent. on all goods imported. In the reign of Henry V. they were first conferred on the king for life; and the same course being followed with his successors, the sovereign began gradually to consider them as his proper right and inheritance, and the vote of parliament as but a formality expressive of the popular recognition of his prerogative. Though these duties were not voted to Henry VIII. until the 6th year of his reign, he, notwithstanding, levied them from the date of his accession. It was, in fact, usual to levy these duties during the period intervening between a sovereign's accession and his first parliament, and this was done by Charles I., as by his predecessors. The Commons, however, in Charles's first parliament accorded these imposts not for life, but for a year only; and the House of Lords objecting to this departure from previous usages, and rejecting the bill, it was attempted to levy tonnage and poundage by the royal authority alone, a proceeding which repeatedly roused the opposition of the Commons. Charles was in 1641 induced to renounce the power of levying these or any other imposts without parliamentary sanction. Charles II. and James II. obtained grants of tonnage and poundage for life, but William III. only for limited periods; and by three statutes of Anne and George I. these imposts were made perpetual, and mortgaged for the public debt. The Customs Consolidation Act in 1787 swept away tonnage and poundage, and similar charges, and substituted a new and single duty on each article. See CUSTOMS DUTIES.

Tonquin. See TONGKING.

Tönsberg, one of the oldest of Norwegian cities and seaports, 71 miles SW. of Christiania by rail, has a large mercantile marine—some 140 ships, including whalers, and a pop. of 4913.

Tonsils. See PALATE.—Tonsilitis (or *Tonsillitis*) is inflammation of the tonsils, a form of sore throat varying much in intensity; see THROAT.

Tonson, a family of London booksellers in the first half of the 18th century. Its founder, Jacob Tonson, the son of a barber-surgeon, was born in 1656, apprenticed in 1670, and commenced business early in 1678 with a capital of £100. Before 1679 he published some plays of Otway and Tate, and as early as 1681 he had secured the patronage of Dryden. In 1700 he published Dryden's *Fables*,

and soon after bought a country-house near the village of Barnes, where as secretary he entertained for many years the members of the famous Kit-Cat Club (q.v.). Tonson was also the first to open Shakespeare to the reading public by producing Rowe's octavo edition in 1709. After 1706 he published some of Pope's works. Tonson had his brother in partnership, and afterwards his nephew, and on his death at Ledbury, April 2, 1736, was succeeded by his grand-nephew, Jacob Tonson the third, who died in 1767. See Charles Knight's *Shadows of the Old Booksellers* (1865).

Tonsure (Lat. *tonsura*), a religious observance of the Roman Catholic and Oriental churches, which consists in shaving or cutting part of the hair of the head as a sign of the dedication of the person to the special service of God, and commonly to the public ministry of religion. By some writers it is represented as of apostolic origin (cf. Acts, xxi. 24); but that it did not prevail in the early ages is sufficiently plain. It would appear that the usage first arose in reference to the monastic rather than the clerical life. Paulinus of Nola, in the end of the 4th or beginning of the 5th century, alludes to it as then in use among the western monks; and it speedily passed from them to the clergy, the crown-like figure being regarded partly as a symbol of our Lord's crown of thorns, partly as an emblem of the 'Royal Priesthood' of the Christian dispensation. The form of the tonsure was different in different churches, and the varieties of it are of some historical interest. That of the Roman Church, called 'the tonsure of Peter,' consisted in shaving the crown as well as the back of the head, so that there remained a circular ring or 'crown' of hair. This was the form in use in Italy, Gaul, and Spain. In the 'Scottish (or Irish) tonsure,' which was in use in Ireland, in North Britain, and in those parts of Germany in which the Irish missionaries had preached, the entire front of the head was shaved, leaving the front bare as far back as the line from ear to ear. This tonsure was called 'the tonsure of James,' and by its enemies that of 'Simon the Magician.' The Greeks and other Orientals shaved *the entire head*. The supposed derivation of the Irish form of tonsure from the apostolic times led to its being held both in Ireland and in Britain, as well as other churches of Irish foundation, to be of the most vital importance. It was in use in the parts of England converted by Scottish missionaries, and was the subject of a violent controversy decided at Whitby in 664 in favour of the Roman usage (which triumphed also in regard to Easter and other peculiarities of the Celtic Church). The tonsure of some monastic orders and friars still leaves but a circle of hair: but the tonsure of secular clergy is quite small. The right to tonsure is with bishops, mitred abbots, cardinal priests, and certain priests with special privilege. Originally the tonsure was merely a part of the ceremonial of initiation in orders, and was only performed in the act of administering the higher order; but about the 7th century it came to be used as a distinct and independent ceremonial; tonsure is not an 'order,' but only a 'preparation for orders.'

Tontine, a term derived from the name of Lorenzo Tonti, a Neapolitan, who settled in Paris in Cardinal Mazarin's time, and proposed in 1653 to raise a fund of twenty-five million livres for the relief of the national exchequer by means of a financial association, of which the great prize should ultimately accrue to the longest liver. There were to be shares of 300 livres. The subscribers were to be divided into ten classes according to age; and for each class a fixed sum was annually to be divided equally amongst the members of the class. In this way, while each member should get fair interest from the first on his capital, the profit falling to survivors would increase as years went on, and the last survivor would receive the whole of the interest due to the class he belonged to. Mazarin and Tonti were both Italians, and regarded in Paris with suspicion, and, in spite of the cardinal's support, the scheme fell through. Tonti for a time received a pension, and was an active promoter of companies; but was ultimately committed to the Bastille, whence he for some years corresponded with his friends. There he seems to have died. But in 1689–92 Louis XIV., sorely in need of money, reverted to the plan of the Italian adventurer, and raised a sum of fourteen million livres by a tontine of forty years' duration. The sole survivor was in 1726 drawing an annuity of 73,500 livres on his original share of 300 livres. The tontine is a lottery of annuities—or compound of lottery and annuity—and was frequently had recourse to in France in the 18th century, with government sanction. Generally, in an association on what is called the tontine principle, a payment is made by each member of the association, and with the capital so formed an annuity, payable at the same rate until all the lives forming the association are extinct, is bought from some company or individual. This annuity is divided among the members according to age and premium paid by each; and on the decease of any member the surplus thence arising is divided among the survivors, and on the death of the last member of the association the total annuity reverts to the source from which it has hitherto emanated. There are various kinds of tontines; and the designation of tontine may, with propriety, be applied to any financial scheme by which it is proposed that gain shall accrue to survivorship.

In Britain tontines have been less popular than in France, but both in England and Ireland these were often established. Three Irish tontines in 1773–77 had 3500 members. The last public one in England was in 1789. In Great Britain they were chiefly set on foot not for purposes of public finance, but to enable a number of small capitalists to build hotels and the like, requiring sums beyond what any one of them singly could raise. Such a tontine was founded at Peebles in 1807; 144 members subscribed £25 each, and risked his share not on his own life, but on any life he chose to name—usually a healthy young child. The persons so named had diminished from 144 to 53 by 1864, and to 11 in 1880; in 1887 the shareholders, reduced by death to two, sold their shares for £2130. In 1871 it was proposed to organise a tontine to take over the Alexandra Park and Palace, but the scheme came to nothing. The United States has had its tontines also: the New York Tontine Association, founded in 1790, was wound up in the years 1870–78. See articles in *All the Year Round* (February 1873) and *Chambers's Journal* (March 1880).

We occasionally hear of Tontine Clubs where the original members have the advantage that the last 100 survivors of their number become proprietors of the Club. The system is a feature of many American insurance societies (see INSURANCE).

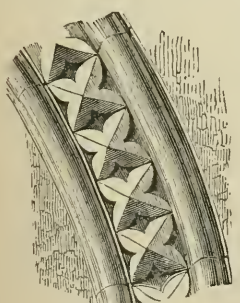
Tooke, JOHN HORNE, was born 25th June 1736, in Newport Street, Westminster, the third son of John Horne, a well-to-do poulterer. He was educated chiefly at Westminster and Eton (where a schoolfellow's pen-knife destroyed the sight of one eye), and then at St John's College, Cambridge. Taking his B.A. in 1758, he entered at the Middle Temple, and for a time was an usher at Blackheath, but in 1760, to please his father, accepted the living of New Brentford. He had neither liking nor reverence for the clerical

profession, and dropped it during two travelling tutorships (1763–65); at Paris he met John Wilkes, and conceived the strongest admiration for him. When in 1768 Wilkes stood for Middlesex 'Parson Horne' pledged his credit for his expenses, and vowed that 'in a cause so just and holy he could dye his black coat red;' but ere long they fell out, and in 1771 had a rasping epistolary controversy. Horne, however, who in 1770 had composed the famous (unspoken) speech of Lord Mayor Beckford to the king, still continued to meddle in politics, and even encountered, not without success, the formidable 'Junius.' In 1773 he resigned his living, and resumed the study of law. About this time his spirited opposition to an enclosure bill procured him the favour (*plus* £8000) of the rich Mr Tooke of Purley in Surrey; and to this were due both his assumption in 1782 of the surname Tooke and the sub-title of his *Epea Pteroenta, or the Diversions of Purley* (2 parts, 1786–1805), that witty medley of etymology, grammar, metaphysics, and politics, which he commenced during an imprisonment in the King's Bench for promoting a subscription for the Americans 'barbarously murdered at Lexington by the king's soldiers in 1775.' In 1779 he found himself debarred from the bar by his orders; in 1790, and again in 1797, stood unsuccessfully for Westminster; in 1794 was tried for high-treason, but acquitted; and in 1801 obtained a seat for the rotten borough of Old Sarum, only, however, to be excluded by a special act from the next parliament (see CLERGY). He died at Wimbledon, his home for the last twenty years, on 18th March 1812, bequeathing his property to his natural children.

See the Life by A. Stephens (2 vols. 1813), and Thorold Rogers' *Historical Gleanings* (2d series, 1870).

Toole, JOHN LAWRENCE, the most popular low-comedian of his day, was born in London on 12th March 1832. Originally intended for city life, he soon gave up the desk and became an actor. He first played at Ipswich, then served an apprenticeship in the provinces, making a great reputation for himself in Edinburgh, Glasgow, and Dublin. He made his first appearance in London at the St James's Theatre in 1854, and played afterwards at the Lyceum with Charles Dillon, at the Adelphi under the management of Benjamin Webster, and at the ill-fated Queen's Theatre in Long Acre. In 1874–75 he played in the United States, and in 1890 in Australia. In 1879 he became lessee of the Folly Theatre, which he enlarged, changing the name to 'Toole's Theatre.' See his *Reminiscences*, chronicled by Joseph Hatton (1888).

Tooley Street, a street in Southwark, at the foot of London Bridge, derives its name from a corruption of St Olave, a church here, and is famous through Canning's story of its three tailors who began their petition to parliament with 'We, the people of England.'



Tooth-ornament.

Toombudra (correctly, TUNGABHADRA), an important tributary of the Kistnah or Krishna, rises in the south-west of Mysore, and after a north-east course of 400 miles joins the Kistnah 16 miles below Karnul.

Toothache. See TEETH, DENTISTRY.

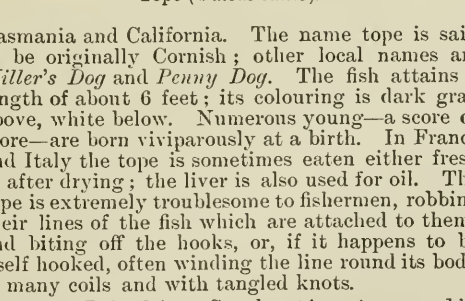
Tooth-ornament, a form of sculptured enrichment much used in the Early English style.

Topaz, a mineral, ranked by mineralogists amongst Gems (q.v.), and the finer varieties of which are much valued both for their lustre and the beauty of their colours. It is composed chiefly of alumina and silica, the former, in general, more than 30 per cent. of the whole, with fluoric acid, and usually a little oxide of iron. It is found generally in primitive rocks, and in many parts of the world—Russia, Siberia, Saxony, Australia, the United States, Cornwall, Aberdeenshire, the Mourne Mountains in Ireland—but those most prized by jewellers are generally from Brazil. Topaz may be colourless, light blue or green, rose-pink, orange, or straw yellow, in great variety of shades. Its crystals are rhombic prisms, generally terminated by four-sided pyramids, but often variously bevelled and acuminated. The prisms are finely striated. The specific gravity is about 3·5. Topaz is translucent or almost transparent on the edges, and is harder than quartz. It is rendered very electric by heat or friction, and by this property a topaz may at once be distinguished from a diamond or ruby, for which otherwise, when cut and set, it might readily be mistaken. A coarse variety of topaz called *Pyrophysalite* occurs near Fahlun in Sweden, which is not crystallised; when reduced to powder it can be used as emery for grinding and polishing. The so-called 'oriental topaz' is a yellow corundum; the 'false topaz' is a yellow variety of vitreous quartz. Topaz derives its name from the *Topazion* of the ancients, which, however, seems to have been a totally different mineral, probably chrysolite.

Tooth Powder. See TEETH, p. 98.

Toothwort, a name for *Lathræa squamaria*, one of the Insectivorous Plants (q.v.); as well as for *Dentaria bulbifera*, one of the Cruciferæ (q.v.) common in England, also known as 'coral-wort' and 'tooth-violet.'

Tope (*Galeus canis*), a small species of shark abundant on the southern coasts of Britain, more rare towards the north. Its range extends to



Tope (*Galeus canis*).

Tasmania and California. The name tope is said to be originally Cornish; other local names are *Miller's Dog* and *Penny Dog*. The fish attains a length of about 6 feet; its colouring is dark gray above, white below. Numerous young—a score or more—are born viviparously at a birth. In France and Italy the tope is sometimes eaten either fresh or after drying; the liver is also used for oil. The tope is extremely troublesome to fishermen, robbing their lines of the fish which are attached to them, and biting off the hooks, or, if it happens to be itself hooked, often winding the line round its body in many coils and with tangled knots.

Tope (Pali *thûpo;* Sansk. *stûpa*, 'a mound'), a Buddhist tumulus for the preservation of relics, of more or less solid masonry, in which the relics were deposited. The oldest topes are spherical; others have polygonal bases; and they were originally crowned with an umbrella-shaped finial, and surrounded by a carved stone railing with elaborately carved gateway. The chief one of a great group at Sanchi near Bhilsa (q.v.), in Central

India, is 42 feet high and 106 feet in diameter. In Ceylon they are called dagobas ; there is an illustration of one in the article CEYLON. Some topes are rock-cut. See also INDIA, Vol. VI. p. 108.

Topee. See TANTIA TOPEE.

Tope'ka, the capital of Kansas, is on both banks of the Kansas River, 67 miles W. of Kansas City by four great railways. It is well built, with wide, shady streets, and possesses a handsome capitol building, a Congregational college, a Roman Catholic seminary, and an Episcopal ladies' college ; while close by are the state asylum for the insane and the reform school. Topeka is the seat of an Episcopal bishop. It has nearly a dozen flour-mills, large railway-shops, several foundries and packing-houses, and manufactories of carriages, pottery, bricks, biscuits, starch, vinegar, tents, windmills, &c. Founded in 1854, it became the state capital in 1861. Pop. (1880) 15,452 ; (1890) 31,007.

Topelius, ZACHRIS (1818–98), Swedish-Finnish poet. See SWEDEN, p. 10.

Töpffer, RODOLPHE, artist and novelist, was born the son of a painter at Geneva, January 31, 1799, and himself studied art, but was obliged by the weakness of his eyes to become a teacher. He founded a boarding-school in 1825, and conducted it till his death, was named in 1832 professor of Rhetoric at the Geneva Academy, and died 8th June 1846. His name is widely known from the delightful *Nouvelles Genévoises* (1841), and from the exquisite little masterpiece of sentiment and fancy, *La Bibliothèque de mon Oncle* (1832). Other novels are *Le Presbytère* (1833) and his last and unfinished work, *Rosa et Gertrude* (1846). Töpffer had a genius for humorous caricature, and the drawings in his two series of *Voyages en Zig-zag* (1843–53) are almost better than the text.

See the Lives by Relave (1886), and Blondel and Mirabaud (1887); also Rambert, *Écrivains nationaux Suisses* (vol. i. Geneva, 1874). See Sainte-Beuve, *Portraits Littéraires*, vol. iii., and *Portr. Contemporains*, vol. iii.

Tophané, a suburb of Constantinople (q.v.).

Tophet. See GEHENNA.

Topknot, the popular name of some small fishes of the same genus as the Turbot (q.v.) and brill. A typical representative is *Rhombus punctatus*, a fish about 6 inches in length and 4 in breadth. It occurs on British and other northern European coasts, living among rocks and seaweed, with which the brown colour spotted with black harmonises well.

Toplady, AUGUSTUS MONTAGUE, hymn-writer, was born at Farnham in Surrey, November 4, 1740, and had his education at Westminster and Trinity College, Dublin. He had been awakened at fifteen in an Irish barn, but it was three years more before he had 'a full and clear view of the doctrines of grace.' He took orders in 1762, and became vicar of Broad Hembury, Devonshire, in 1768. During the last three years of his life he preached in a chapel near Leicester Fields in London ; and here he died, August 11, 1778. A strenuous defender of Calvinism, he was a bitter controversialist, and is not sparing in terms of abuse, even of Wesley himself. His work, *The Church of England vindicated from the Charge of Arminianism* (2 vols. 1774), is safely forgotten, as it deserves to be ; but his name survives secure of immortality in a hymn like 'Rock of Ages.' As early as 1759 he had published at Dublin *Poems on Sacred Subjects ;* his *Psalms and Hymns* (1776) was a collection, with but few of his own. The best edition of his whole verse is that by D. Sedgwick (1860) ; of his entire works collections were published in six vols. in 1794 and in 1825. See Bishop Ryle's *Christian Leaders of a Hundred Years Ago* (1869).

Töplitz. See TEPLITZ.

Top-shell. See TROCHIDÆ.

Torbanehill. See BOGHEAD COAL.

Torfæus. See ICELAND (LITERATURE).

Torgau, a town of Prussia, and a fortress of the second rank, stands on the left bank of the Elbe, 70 miles SSW. of Berlin by rail. The river is here crossed by an old bridge and a railway bridge. Among the public buildings are the castle, now used as barracks, and containing a church consecrated by Luther in 1544 ; a town-church, with pictures by Cranach, and the grave of Luther's wife ; and an old town-hall. Here on 3d November 1760 Frederick the Great defeated the Austrians. Pop. 10,988.

Tormentil (*Potentilla*), a genus of plants of the natural order Rosaceæ, sub-order Potentilleæ, differing from other species of Potentilla (q.v.) only in the four-parted calyx and corolla. The Common Tormentil (*Tormentilla officinalis*, or *P. tormentilla*) is a very common plant in moorish and heathy places in Britain and throughout great

Tormentil (*Potentilla tormentilla*).

part of Europe. It has a large woody root, which has long been officinal, being an agreeable and efficacious astringent, useful in diarrhœa and other complaints, and which contains tannin, gum, and a red colouring matter.

Tornado. See STORMS, WHIRLWIND.

Tornea, a town in the Finnish government of Uleåborg, at the mouth of the Tornea River, which, rising in the Tornea lake, forms during great part of its course of 250 miles the boundary between Sweden and Finland. Pop. 1015 ; across the river is the Swedish town of Haparanda.

Toro, a town of Spain, on the right bank of the Douro, 20 m. E. of Zamora by rail. Pop. 8722.

Torontál, the Hungarian county on the Maros and Theiss, with Becskerek (q.v.) for capital.

Toronto, second in importance among the cities of Canada. As Montreal is the metropolis of the east and of so much of the west as its great railway facilities enable it to control for business purposes, so Toronto aims to be the metropolis of the west, including the newly-opened regions of the North-west.

The name is derived from the Huron word signifying 'place of meeting.' In 1749 the French established a chain of posts or forts through all the west and down the Mississippi Valley, and two forts, one at Kingston, Fort Frontenac, and one at Toronto, called Fort Rouillé. In 1756 this fort, on the west side of the present city, was destroyed to prevent its falling into the hands of the English. In 1793 Governor Simcoe finding Niagara or Newark too close to the

American side—indeed, right under the guns of an American fort—for the seat of government, crossed Lake Ontario and established his headquarters in a tent on a site to the east of the present city. In this tent he passed a whole winter before a government house could be erected for his use. In 1812 Toronto, called York by Governor Simcoe, was captured and burned and looted twice in the same year by the American army and navy. In 1834 it was incorporated as a city with its present name Toronto. In 1837 it was the scene of a brief and ineffectual rebellion under Lyon Mackenzie (q.v.). Since that time its history has been purely civic, without other interest than that attaching to prosperous growth. The growth of population has been rapid. In 1793, when Governor Simcoe landed, there were only two Indian families. In 1834 the population was less than 10,000. In 1861 it had increased to 44,821, in 1871 to 56,092, and in 1881 to 86,415. In 1891, including some annexed suburbs, it amounted to 181,220.

The city is the capital of the province, and all the departments of the provincial government are centred in Toronto. The lieutenant-governor resides there, and the official residence is a handsome building. The local legislature meets annually in the building prepared for the earlier legislature of a united Canada (before 1840). The Dominion government has also great establishments in Toronto in the custom-house, post-office, internal revenue offices, and a meteorological observatory. The law-courts are centred in Osgoode Hall, a very stately and roomy building.

The principal ecclesiastical buildings are the cathedral of St James (Anglican), the Metropolitan Methodist Church, and St Michael's Cathedral (Catholic). In educational institutions Toronto is very rich. The university of Toronto, which was burned to the ground in 1890, was a very imposing structure, and, restored on the old plan, is well worthy of its noble site and splendid grounds. The professorial staff numbers about 21, and the number of students in attendance averages 400. There are also Trinity College (Anglican), Wycliff College (Protestant), Knox College (Presbyterian), Macmaster Hall (Baptist), St Michael's College (Catholic), besides the Normal School, Collegiate Institute, endless public schools and separate (Catholic) schools and convents; and there are schools of pharmacy, dentistry, and veterinary science. Toronto has a Public Library (1884) which now contains about 40,000 volumes; the University Library, destroyed in the fire of 1890, but gradually gathering up again; the Law Library (20,000 volumes); the library of the Canadian Institute; and the Legislature Library, which has about 30,000 volumes. Each of the colleges has a select library for its own purposes.

The commerce of Toronto has grown with the growth of the city. Between 1870 and 1890 the imports increased from little over $7,000,000 to over $20,000,000 per annum, and the development has gone on since; the exports grew from $1,000,000 or so to over $3,000,000. The lake commerce in lumber, fruit, grain, coal, and cattle is large. The shipping on the lakes is laid up in winter. The manufactories comprise iron-foundries, engineer-shops, railway works, rolling-mills, breweries and a distillery, cabinet works and carriage factories, tanneries, soap-works, bootmaking establishments, sash and door factories, and pork-packing houses. Banking is largely represented in the city; and there are numerous newspapers and periodicals published here.

Toronto became the adopted home of Sir Daniel Wilson and of Professor Goldwin Smith, and was for a time the residence of Mrs Jameson the art critic.

See the article ONTARIO; also CANADA and works there cited.

Torpedo, a genus of cartilaginous fishes of the family Torpedinidæ, related to the skates and rays. They are most remarkable for their electric organs, which lie on each side of the head (see ELECTRIC FISHES, with illustrations). The electric shock is powerful enough to kill small animals, and specimens 2 or 3 feet wide can by a single discharge disable a full-grown man. The genus, which includes about six species, is widely distributed over the Atlantic and Indian Oceans; *T. marmorata* and two others are common in the Mediterranean, and *T. hebetans* reaches the south coasts of Britain.

Torpedo. The term torpedo is now used to denote a submarine weapon of offence, carrying a charge of gun-cotton or other explosive, and possessing powers of locomotion, in distinction to a submarine mine (see MINES), which is stationary and used for defensive purposes. Torpedoes may be divided into two classes: (1) *Uncontrollable*, being those which carry within themselves their own motive power, and which after being once started are no longer under the control of the operator; and (2) *Controllable*—i.e. those whose motive power is under the control of the operator, who can by electricity or other means direct the movements of the torpedo during its run. Of the first the best-known examples are the Whitehead and the Howell; and of the second the Brennan, Sims-Edison, and Lay. Of these the most important is the Whitehead, which dates from about 1867.

The general arrangement of this weapon is shown in the figure: it is cigar-shaped, made of steel or bronze, and varying from 12 to 18 inches in diameter, and from 10 to 16 feet 6 inches in length, the most common size being 14 inches in diameter and 14 feet 6 inches long. The head A is conical and contains the charge of gun-cotton, which in the 14-inch torpedo varies from 32 lb. in the earlier patterns to 70 lb. in the later ones. The pistol, P,

on coming in contact with the enemy's ship is driven back on to a small charge of fulminate of mercury which detonates the gun-cotton. B is the air-chamber which contains the compressed air for driving the engines. The air is forced into this chamber by means of air-pumps to a pressure of ninety atmospheres. C is the balance chamber, and contains the mechanism by which the depth of the torpedo below the surface is regulated during its run. The depth of the torpedo can be adjusted before starting to any required amount between 5 and 20 feet. In D are the engines worked by the compressed air. E is the buoyancy chamber. F is the tail, consisting of two screws placed one in front of the other for propelling the torpedo, two small vertical rudders which are adjusted by experiment to keep the torpedo running in a straight line, the horizontal rudders which are controlled by the mechanism in the balance chamber and which keep the torpedo at the depth for which it has been set, and four fins, two horizontal and two vertical, to prevent rolling.

The torpedo is discharged from a tube either above water or below the water-line. In the latter case special arrangements are made. In above-water tubes the torpedo fits the tube like a projectile in a gun, and is ejected either by a small charge of powder or by compressed air. As the torpedo leaves the tube the valve controlling the supply of air to the engines is opened, and the torpedo on entering the water is propelled by its

own engines. A safety arrangement on the pistol prevents the latter exploding the charge by accident until the torpedo is clear of the ship. The speed of the later patterns of 14-inch torpedoes is 26 knots for 600 yards. In action it can be adjusted to sink at the end of its run in the event of its missing its object, and when used for exercise it is adjusted to float, and can then be picked up and used again. For various reasons it is considered that the effective range of a Whitehead torpedo is not more than 400 yards, and although the torpedo is capable of going much farther, it is desirable, in order to ensure a fair measure of success, not to discharge the torpedo until within that distance of the enemy.

The position which the Whitehead torpedo is destined eventually to take in naval warfare is to a great extent a matter of speculation. There have been instances in recent wars where it has been used with success even with the inferior weapons and apparatus then in use. On the other hand, torpedoes occasionally take most erratic courses, and no one can predict with certainty what direction one will take. Moreover, in consequence of the slow speed of a torpedo as compared with a projectile, and also on account of the deflection it receives on entering the water, it is necessary in discharging it to take into consideration the speed of one's own ship and also the speed and course of the enemy; and as the two latter must necessarily be more or less guess-work, an additional element of error is introduced. Another objection, the importance of which can only be determined in war time, is that during the time the torpedo is waiting to be discharged the charge is liable to be detonated by an enemy's shot, the results of such an accident being obviously of a most disastrous character. The torpedo is, however, at present recognised as a most important element in naval warfare, and its use must of necessity be continued until war has decided definitely in its favour or otherwise. A very much more powerful type of Whitehead is 18 inches in diameter, carrying a charge of about 200 lb. of gun-cotton, and having a speed of about 30 knots for 800 yards. Torpedoes are now usually discharged below, not above, water.

The *Howell torpedo* may be described as in shape similar to the Whitehead, and is propelled by screws to which motion is imparted by means of a heavy flywheel in the interior of the torpedo which is spun up to 10,000 revolutions a minute, before discharging, by means of suitable machinery. This wheel, in addition to providing the requisite energy, also acts as a gyroscope, the result of which is that the torpedo continues to run in the direction of the line of fire, and cannot be deflected from its course. The application of the gyroscopic principle to torpedoes is new and ingenious, and its development will be watched with interest. The charge is exploded on contact.

The *Brennan torpedo* carries inside it two drums on which are wound piano wire which, passing out of the rear of the torpedo, is connected with powerful engines on shore. On these being started the wire is reeled off the drums in the torpedo, the motion of the drums being imparted to the screws. The faster the wire is reeled up on shore, the faster will the torpedo go ahead. Steering is effected by checking one or other of the wires which actuate vertical rudders on the torpedo. The charge is exploded on contact, and the range is a mile or more.

The *Sims-Edison torpedo* consists of a 'float' to which is suspended the torpedo so that it is about 6 feet below the surface. The motive power is supplied by an electric motor in the torpedo worked from a generator at the base through an electric cable which is paid out as the torpedo advances. The *Lay torpedo* is propelled by carbonic acid gas contained in the torpedo under pressure, the engines being controlled by the operator through an electric cable. The charge in both these torpedoes is exploded by electricity at will, and the speed in each is about 10 or 11 knots for one mile.

The three last torpedoes are connected to the base from which they start, by means of wires, and it would be a matter of very great difficulty to control these torpedoes, and to direct their course so as to strike any particular object, if they were used from a moving base. Hence any proposals to use them on board ship have not so far met with much favour, and it is unlikely that this class of torpedo will ever be used except from forts or fixed stations on shore.

The *Outrigger torpedo* is used from steam pinnaces, and consists of a charge of gun-cotton placed at the end of a pole about 40 feet long, which projects over the bows of the boat, the charge being about 10 feet below the surface when in position. The boat in making an attack has to bring the charge in contact with the bottom of the enemy's ship, and it is then exploded by electricity. A notable instance of the success of this method of attack occurred during the American civil war; but under present conditions an attack on a modern ship with the outrigged torpedo must be regarded as impracticable except under very exceptional circumstances.

Torpedo Boats.—If a large ship is to be attacked by a comparatively small boat, the latter, in order to have any chance of success, must be as nearly invisible as possible, and must possess a high speed. Torpedo boats designed to fulfil these requirements vary considerably in size, but may be broadly divided into two classes—those which can be carried on board large ships, and which are therefore limited in size and possess small sea-going powers; and those which can take the sea and act independently. The two classes are similar in construction, being built of the lightest steel, low in the water, and with most of the available space occupied by the engines and apparatus connected with the torpedoes. The former class are about 60 feet in length, 15 knots speed, and carry a crew of eight men. The latter range from 100 to 150 feet in length, have a nominal speed of from 19 to 22 knots, which in practice rarely exceeds 17 to 20 knots, and carry a crew of from sixteen to sixty men, with three to five torpedoes, and also a small gun armament.

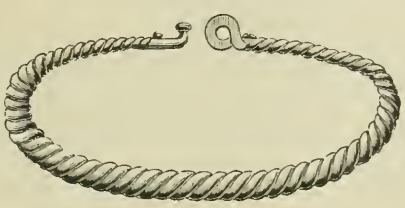
There is also an intermediate class of vessel, known as torpedo-boat destroyers, carrying an armament of machine guns and torpedoes. These vessels are of high speed, and their superior size and sea-going qualities enable them to maintain their speed in the open sea far better than a torpedo boat, whilst their powerful armament would render them formidable opponents even to large ships.

For torpedo-nets, see NAVY, Vol. VII. p. 421. For part of the history of submarine warfare, see SUBMARINE NAVIGATION. See also Sleeman's *Torpedoes and Torpedo Warfare* (1880; 2d ed. 1889).

Torquay, a watering-place of South Devon, occupying a cove on the north side of Tor Bay, 23 miles S. of Exeter and 220 WSW. of London. Tor Abbey was founded here for Premonstratensian monks in 1196; and Tor Bay is famous in history as the place where in 1688 William of Orange landed at Brixham (q.v.), and during the war with France was often used as a naval rendezvous. But till the beginning of the 19th century Torquay itself was little more than an assemblage of fishermen's huts. About that time the advantages of its climate—which are a peculiarly sheltered position, an equable temperature (mean 44° in winter, 55° in summer), and freedom from fogs—caused it

to be resorted to by consumptive patients, and it soon acquired a European celebrity, which still is almost unrivalled. The romantic hills and valleys of Torquay and its environs have been overspread with terraces, villas, and gardens, the luxuriance of its foliage being a delightful feature of this 'queen of English watering-places.' The scenery is as varied as it is beautiful, the geology of the district most interesting; and Kent's Cavern (q.v.) is only a mile distant. The remains of the abbey include some crypts and the 13th-century 'Spanish barn' (so called from its having housed some survivors from the Armada); and St Michael's Chapel, on a hill-top, is thought to have been connected with the abbey. St John's Church, by Street, is a striking Early English edifice; and other buildings are the town-hall (1852), museum (1875), and theatre (1880). Torquay is a great yachting station; its chief industries are the working up of Devonshire marbles and the manufacture of terra-cotta. Pop. (1851) 7903; (1881) 24,767; (1891) 25,534. See J. T. White's *History of Torquay* (1878).

Torque (Lat. *torqueo*, 'I twist'), a species of gold ornament, worn round the neck or arm, which was much in use in ancient times, both among Asiatic and north European nations. It consisted of a spirally-twisted bar of gold, bent



Torque.

round nearly into a circle, with the ends free, and terminating in hooks, or sometimes in serpents. These ornaments seem to have formed an important part of the wealth of those who wore them, and of the plunder obtained by the Roman conquerors from a Celtic or oriental army. Numerous examples have been dug up in Great Britain and Ireland, as well as in France.

Torquemada, Thomas de, the first inquisitor-general of Spain, was born at Valladolid in 1420, and died at Avila, 16th September 1498. He became prior of a Dominican monastery at Segovia, and succeeded in persuading Ferdinand and Isabella to crave from the pope the appointment of the 'Holy Office' of the Inquisition (q.v.). Torquemada was appointed its head, and began in 1483 that infamous work which has left his name a by-word for pitiless cruelty. He has given a subject to Longfellow and to Hugo.

Torre dell' Annunziata, a thriving town of Southern Italy, stands on the south base of Mount Vesuvius, 13 miles SE. of Naples by rail. A fishery and a coasting trade are carried on. Pop. 20,060.—Torre del Greco, another town at the base of Vesuvius, is only 7 miles from Naples by rail, and has been repeatedly destroyed by eruptions. Fishing is a great source of occupation, and coral is worked. Pop. 21,588.

Torrens, Lake, sometimes a brackish lake, at others merely a vast salt-marsh, in South Australia. It lies 90 miles N. of Spencer's Gulf. Usual length, about 130 miles by 20 miles broad. It is named after Sir R. R. Torrens (1814–84), who between 1841 and 1874 held many important offices in the colony, and is best known for his Land Titles Registration Act.

Torre Pellice (Fr. *La Tour*), a Piedmontese village of 2900 inhabitants, 34 miles SW. of Turin by rail. It is the headquarters of the Waldenses (q.v.), with a college, and some manufactures of cotton-cloth and silk.

Torres Strait lies between the northernmost part of Australia and New Guinea. The channel is from 80 to 90 miles in width; and its navigation, though practicable, is rendered dangerous and difficult by the innumerable shoals, reefs, and islands with which it is strewn. It was discovered in 1606 by Luis Vaez de Torres, a Spanish navigator sent out by the viceroy of Peru. See map at New Guinea, and *Nature*, October 1890, p. 637.

Torres-Vedras, a town of the Portuguese province of Estremadura, 26 miles N. of Lisbon by rail. It is known from those famous lines of defence within which Wellington defended himself the winter of 1810–11 against Masséna. There were three such lines of fortification; and the area within the lines was about 500 sq. m. Hence Wellington issued on that career of slow and hard-won victory which ended in the expulsion of the French from the Peninsula. Pop. 4926.

Torricelli, Evangelista, mathematician and philosopher, was born at Piancaldoli in the Romagna, 15th October 1608. He was brought up by an uncle who resided at Faenza, and who put him under the tuition of the Jesuits. When twenty years old he was sent to Rome, and there devoted himself to mathematical studies. Galileo's theories on force and motion engaged his attention, and led to his writing a *Trattato del Moto* (about 1641), and to his being invited by Galileo (1641) to visit him; on the old philosopher's death, three months afterwards, he was appointed mathematician to the grand-duke, and professor to the Florentine Academy. Here he resided till his death, 25th October 1647. His great discovery was the interpretation of the previously known fact that water will rise in a suction-pump only to the height of about 32 feet—the idea that the column of fluid is sustained by the pressure of the atmosphere on the open surface of fluid (see Barometer). The vacuum in the barometer is the Torricellian vacuum; and the barometer is sometimes called the Torricellian tube. Torricelli also effected the quadrature of the cycloid—in this he was anticipated by Roberval—and made other mathematical discoveries. To him is due the fundamental principles of Hydromechanics (q.v., Vol. VI. p. 32); and he made and greatly improved both telescopes and microscopes.

Torrigiano, Pietro (1470–1522), the Florentine sculptor who, according to Cellini, broke Michelangelo's nose in a quarrel, served as a mercenary soldier, and came to England in 1509 to erect the tomb of Henry VII. and his queen, still in Westminster. He executed other works which were destroyed at the Reformation; and settling in Spain, died in the prisons of the Inquisition.

Torrington, a market-town of North Devon, on an eminence sloping to the Torridge, 10 miles (by rail 14) SSW. of Barnstaple. A castle (1340) has disappeared; and the church, of which Wolsey and John Howe were incumbents, was rebuilt in 1651, its predecessor having been accidentally blown up with 200 prisoners, after Hopton's defeat here by Fairfax, February 16, 1646. Torrington, which was made a municipal borough by Queen Mary, gave the title of earl to Monk (q.v.) and in 1689 to Admiral Arthur Herbert (1647–1716), of viscount to Admiral George Byng (q.v.). Gloves are manufactured. Pop. (1851) 3308; (1891) 3436.

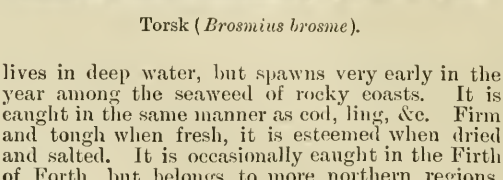
Torshok, an ancient town of Russia, in the government of Tver, 310 miles SE. of St Petersburg by rail. Pop. 14,574.

Torsion is the kind of strain produced in a bar or wire when one end is kept fixed and the other is rotated about the axis. The axis itself is in no way changed, but every other line originally parallel thereto takes the form of a helix or screw. The torsion is measured by the inclination of the diameter of any section to the diameter originally parallel to it of the section at unit distance. The moment of the forces which produce the torsion is called the torsional stress or *torque;* and the coefficient of torsion is the ratio of the stress to the strain. The coefficient of torsion depends on the Rigidity (q.v.) of the material and upon the size and form of the bar. For wires and bars of circular section the coefficient of torsion varies as the fourth power of the radius. That is, to produce the same torsion in two wires whose diameters are as 2 to 1, we must apply, in the case of the thicker wire, a torsional stress 16 times greater than that needed for the thinner wire. By the manufacture of excessively thin quartz fibres Professor Boys has obtained torsional coefficients of very minute magnitude.

Torsion-balance is a form of apparatus in which the torsion of a wire is used for the measurement of various kinds of forces. In this way Coulomb discovered the fundamental laws of electric and magnetic attraction (see ELECTRICITY) and Cavendish measured the density of the Earth (q.v.). By means of his quartz fibres Professor Boys has been able to reduce into a very small compass the whole apparatus for making the Cavendish experiment.

Torsion, in Surgery, is a method of common application for the purpose of checking arterial hæmorrhage in certain cases. The wounded vessel is drawn out and fixed by a pair of forceps a quarter of an inch from the end; the end of the artery is then twisted round till it will not untwist itself. It is especially useful when there are many small arteries wounded in an operation, as, for example, in the extirpation of a large tumour.

Torsk, or, by corruption, TUSK or CUSK (*Brosmius brosme*), a valuable fish of the cod family (Gadidæ), abundant in the northern parts of the Atlantic. It measures from 18 inches to 3 feet in length. The head is small, with one barbule under the chin; the single dorsal fin is long; the tail is rounded. The head is dusky, the back and sides yellow, passing into white on the belly. The torsk



Torsk (*Brosmius brosme*).

lives in deep water, but spawns very early in the year among the seaweed of rocky coasts. It is caught in the same manner as cod, ling, &c. Firm and tough when fresh, it is esteemed when dried and salted. It is occasionally caught in the Firth of Forth, but belongs to more northern regions, and is very abundant in the Shetland Isles, the Faroes, on some parts of the coast of Norway, and on the south and west coasts of Iceland. Another species (*B. flavescens*), with two barbules, occurs on the Newfoundland banks.

Torso (Ital.), strictly, signifies a trunk—e.g. the trunk of a tree—but is specially applied to a statue of which only the body remains.

Torstensson, LENNARD, Count of Ortala, a Swedish general, was born at Torstena on 17th August 1603. He accompanied Gustavus Adolphus to Germany in 1630, distinguished himself in the battles of his great master, and after his death fought under Bernhard of Saxe-Weimar and Banér, and in 1641 he was appointed to the supreme command of the Swedish army in Germany. He invaded Silesia, and, when driven back by the imperialists, turned and crushingly defeated them at Breitenfeld (2d November 1641). The next winter he hastened north, and in six weeks swept the Danes out of Holstein, and then drove the Austrians, who had thought to assail him in the rear, ignominiously back all the way to Bohemia. In 1645 he advanced to the walls of Vienna. He died at Stockholm on 7th April 1651.

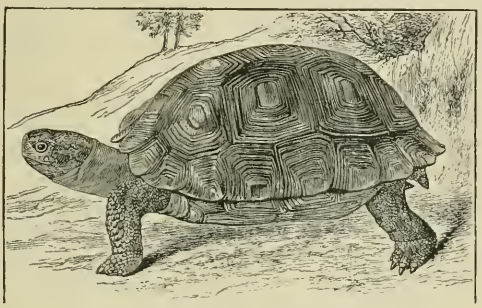
Tort (Lat. *tortus*), in the law of England, includes all those wrongs, not arising out of contract, for which a remedy by compensation or damages is given in a court of law. Such are assault, false imprisonment (i.e. arrest or detention without legal justification), unlawful detention or conversion to one's own use of the goods of another, &c. Deceit also is a tort, if a person suffer damage by acting on an untrue statement made with the intention that he should act on it. The general rule of law was that the right of action for a tort died with the person who committed it; but this defect has been cured by statute to a certain extent. If the wrong was done within six months preceding the wrong-doer's death, an action may be brought against his executors within six months after they have assumed office. So if the injured party lived he could always bring an action of damages; but if he died his executors or relatives could not do so until Lord Campbell's Act enabled the wife, husband, parent, or child of such deceased injured party to sue for damages; and in such case the jury may apportion the damages between the widow and children who sue. The right to bring an action for a tort is limited to two, four, or six years respectively, according to the nature of the wrong. In Scotland there is no time limited for bringing the action. The law of the United States is founded on that of England.

See treatises on torts by Addison (1857; new ed. 1887), E. W. Ball (1884), M. M. Bigelow (3d ed. Boston, 1886), T. M. Cooley (2d ed. 1888), A. Underhill (5th ed. 1889), Clerk and Lindsell (1889), Sir F. Pollock (4th ed. 1895), and L. C. Innes (1891).

Tortoise-plant, a South African name for Elephant's Foot (q.v.).

Tortoises and **Turtles** (*Chelonia*) form a well-defined order of Reptiles, distinguished especially by the dorsal and ventral shields which protect the body. Although terrestrial Chelonians are often called tortoises, and aquatic Chelonians turtles, the distinction cannot be sustained. The dorsal shield or carapace, within shelter of which the head, limbs, and tail can be more or less completely sheltered, is formed (*a*) along the middle line by the vertebræ whose neural spines are flattened, (*b*) by expansions of the parts which in other animals form well-defined ribs, and (*c*) along the edge by marginal plates ossified in the under skin or dermis. The dorsal vertebræ and ribs are thus rigidly involved in the carapace; the neck and the tail are the only flexible parts. The ventral shield or plastron consists of nine bony pieces, one anterior and four on each side. They arise as membrane bones in the dermis. Overlapping, but not corresponding to the bones of the shields, are horny epidermic plates of 'tortoise-shell,' which although hard are not without sensitiveness, numerous nerves ending upon them. The bones of the skull are immovably united together; there

are no teeth, although in an embryonic turtle (Trionyx) traces of them have been detected. The limbs are very typical, and the girdles, which are over-arched by the ribs in the course of development, are well developed. There is no breastbone, and, according to most authorities, there are no clavicles. The brain of the adult Chelonian shows a slight curvature, and, as in all higher vertebrates except snakes, there are twelve cranial nerves, two more than occur in amphibians and fishes. The heart, as in other reptiles except crocodiles, is anatomically three-chambered, but the presence of an incomplete partition in the ventricle makes it work almost as if it had four chambers. The food-canal, ureters, and genital ducts open into a common cloaca, to the wall of which in the males a penis is attached. The large lungs are fixed along the dorsal wall of the thorax. As the body is boxed in by shields which are often quite rigid, the contraction and expansion of the lungs in respiration must be due partly to their own elasticity, partly to the movements of the viscera with which they are closely connected, and partly to the changes which result when the animal retracts or extends its head and limbs. At the



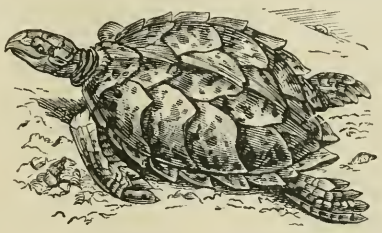
Tortoise (*Testudo elephantopus*).

best the respiration is sluggish; and, as this will affect the whole pitch of the animal's life, the sluggishness may be regarded as the price paid for the very strong armature.

Tortoises excel most animals in their tenacity of life. They can live for a long time without food; they are very difficult to kill, and even after the brain has been destroyed life lingers long in the body. It is said that a headless tortoise has been observed to walk 200 yards twenty-four hours after decapitation; and it is well known that the heart removed from the body will, if carefully suspended in a moist chamber, continue capable of beating for two or three days. All Chelonians are oviparous. The eggs have a firm shell, which is in most cases rigidly calcareous. They are usually laid in the sand or mud, and left to be hatched by the warmth of the sun.

There are two sub-orders of Chelonians—(*a*) Athecata, in which the carapace is flexible; and (*b*) Testudinata, in which it is rigid. The Athecata are represented by one living species, the Trunk-back or Leather Turtle (*Sphargis coriacea*), the largest modern Chelonian, sometimes measuring six feet in length, and sometimes weighing over a thousand pounds. It is widely but very sparsely distributed in tropical and temperate seas—in the Atlantic, Pacific, and Indian oceans, and in the Mediterranean. It is said to be herbivorous.

The Testudinata include four families—Chelonidæ, Testudinidæ, Chelydidæ, and Trionychidæ. The Chelonidæ are strong marine turtles, with flipper-like feet, and broad, partially ossified shields. A well-known representative is the Green Turtle (*Chelone mydas* or *viridis*), which occurs along the Atlantic coast from southern Brazil to Cape Hatteras. It feeds on the roots of the sea-grass (Zostera), and attains a very large size (sometimes weighing 850 pounds), and is the most important of the edible turtles. Both the flesh and the eggs are much esteemed. Notable, also, is the Hawk's-bill Turtle (*Caretta* or *Eretmochelys imbricata*), a ferocious carnivorous form occurring



Hawk's-bill Turtle (*Caretta imbricata*).

along the coasts of the United States, and supplying most of the commercial 'tortoise-shell.' The flesh is slightly esteemed, but the eggs are palatable. The same is true of the Loggerhead (*Thalassochelys caouana* or *Caouana caretta*), a large Atlantic turtle, also carnivorous in habit. The Testudinidæ are terrestrial Chelonians, such as the Greek Tortoise (*Testudo græca*) often brought from Mediterranean countries to Britain, where it usually leads a miserable existence as a pet. Notable are the gigantic forms (*Testudo elephantopus*, &c.), which were once abundant in the Galapagos Islands and in some islands of the Indian Ocean, but are now in process of rapid extermination. The Chelydidæ are Chelonians with long necks which are not retractile within the carapace. The strangest of these is the bearded Turtle (*Chelys matamata*), a carnivorous form once abundant in fresh-water pools in tropical South America. The Trionychidæ or soft-shelled turtles, are fresh-water forms with depressed bodies, covered with soft skin, and webbed yet partly clawed feet. A typical representative is *Aspidonectes ferox*, which lives in the rivers flowing into the Gulf of Mexico, and is famous for its activity, voracity, and fierceness. They usually measure rather over a foot in length. Their flesh is very palatable. See also TERRAPIN.

According to another classification, the Testudinata are divisible into two groups, distinguished by the manner in which the head is retracted. In one set—the Cryptodirans, or hidden-necked Chelonians—'the head is drawn directly within the margin of the shell by the bending of the neck in an S-like manner in a vertical plane.' In the other—the Pleurodirans, or side-necked Chelonians—'the neck is bent sideways, so that the head, when retracted, lies on one side of the front aperture of the shell near one of the legs.'

TORTOISE-SHELL, the large scales of the carapace or shield of a species of sea-turtle, the *Caretta imbricata* (see above). Tortoise-shell is so called because formerly the order of animals to which it belongs was little known, and all were confounded under the general name of Tortoises. A remarkable peculiarity in this species is the arrangement of the thirteen plates forming the carapace, which, instead of being joined together by their edges so as to make apparently one piece, are thinned off at their edges, and overlap each other like the tiles of a roof. They vary in size according to the part of the shield they occupy. The larger are sometimes from a foot to 18 inches long, by 6 inches broad; the thickness rarely exceeds the eighth of an inch. The beautiful mottled colour and semi-transparent characters of this material are well known. A remarkable quality

is possessed by tortoise-shell which very greatly increases its usefulness for the ornamental purposes to which it is generally applied—i.e. the property of being easily softened by a heat equal to boiling water, and of retaining any form when cold which has been given to it when heated. Pieces can also be welded together by the pressure of hot irons properly applied. In Britain the chief use of tortoise-shell is making combs for the hair; but it is also used for inlaying ornamental furniture and various other fancy objects. By the French cabinet-maker Boule (see BUHL) it was used most effectively in combination with brass as a veneer for rich furniture, and all boule or 'buhl' work consists of such a veneering combination. In India, China, and Japan many articles are made of it, showing great skill and taste.

Tortola. See VIRGIN ISLANDS.

Tortona, a town of Northern Italy, on a small tributary of the Po, by rail 13 miles E. of Alessandria. Pop. 7147.

Tortosa, an old town of Spain, 40 miles SW. of Tarragona by rail, on an eminence overlooking the Ebro, 20 miles from its month, with some trade and manufactures. Pop. 26,400.

Tortugas (Sp., 'turtles'), DRY, a group of ten islets or keys belonging to Florida, at the entrance of the Gulf of Mexico, 120 miles WSW. of Cape Sable. They are very low, and partly covered with mangrove bushes; on Garden Key there is a lighthouse, and also a fort.

Torture has been largely used in many countries as a judicial instrument for extracting evidence from unwilling witnesses, or confessions from accused persons, and in the despotisms of the East is still so used; the callousness of torturers and tortured being almost equally remarkable. In ancient Athens slaves were regularly examined by torture. Under the Roman Republic only slaves could be tortured; under the Empire torture, besides being much used in examining slaves, was occasionally inflicted even on freemen, to extract evidence of the crime of *læsa majestas.* Cicero and other enlightened Romans wholly condemned its use. Until the 13th century torture seems to have been unknown to the canon law; about that period the Roman treason-law began to be adapted to heresy, the notions on which the Ordeal (q.v.) was based contributing to promote its use. At a later period torture came to be largely employed by the Inquisition, and it was only in 1816 that it was prohibited by a papal bull. Its use was universal in the witchcraft trials, and accounts for the strange uniformity in confessions.

From the civil law torture became a part of the legal system of most European countries. It was adopted early, and to a large extent, by the Italian municipalities. In Germany elaborate apparatus for its infliction existed, not merely in the dungeons of the feudal castles, but in the vaults beneath the town-halls of Nuremberg and Ratisbon. 'Horrible tortures were constantly inflicted in the 16th and 17th centuries; the 'second degree' included crushing the thumbs, feet, or head in iron apparatus, and the 'third degree' burning the sides, arms, and finger-nails with fire or red-hot irons and pincers. Torture continued to be practised in many of the prisons of Germany when they were visited by Howard in 1770; but in Prussia it was abolished in 1740–54, and the example of Frederick the Great contributed greatly to its final suppression. In Hanover it was not formally abolished till 1840. The torturing of prisoners was carried to a great height in the Low Countries under Philip II. Savonarola and Galileo are amongst famous men who suffered torture. In France it was part of the judicial system till 1789, and in Scotland it was still in frequent use after the Restoration, and was only abolished in 1708. Torture in its most pitiless form was a characteristic feature of the atrocious Templar trials in France. Amongst enlightened men who denounced the worthlessness of confessions secured by torture Bayle, Thomasius, Voltaire, and Beccaria deserve mention. In Naples torture was in use in 1860.

The use of torture seems always to have been repugnant to the genius of the law of England: though occasionally used by an exercise of prerogative, it may be doubted whether it was ever recognised as lawful in the ordinary course of the administration of justice. It was employed by royal warrant in the Templar trials (1310), and we are told that till that time it was unknown in England. During the Tudor period the Council assumed the power of directing torture-warrants to the lieutenant of the Tower, and other officers, against state prisoners, and occasionally also against persons accused of other serious crimes; and similar warrants were at times issued under the sign-manual. Under James I. and Charles I. torture was less resorted to, and only in state trials. In 1628, in the case of Felton, the assassin of the Duke of Buckingham, the judges declared the examination of the accused by torture, for the purpose of discovering his accomplices, to be illegal. Torture was inflicted in England as late as 1592, in the case of the Jesuit Southwell (q.v.), in 1640 on Archer, who took part in an attack on Laud's palace, and as late as 1646 on witches. As late as 1806 Sir Thomas Picton (q.v.) was tried for having, as governor of Trinidad, permitted a woman to be tortured under old Spanish laws. Torture is now disused in all countries of Europe, and is universally acknowledged to have been a most unsatisfactory mode of getting at the truth; often leading the innocent, from weakness, to plead guilty to crimes they had not committed.

The instruments of judicial torture have been various. The most celebrated is the Rack, the Boot, and Thumbscrew. More ingenious instruments were such as the Scavenger's Daughter (rather 'Skeffington's Daughter,' from a lieutenant of the Tower under Henry VIII.), a spiked iron frame, which closed its victim in a deadly embrace. The *Peine Forte et Dure* (q.v.) was a terrible form of torture. From torture for the sake of extracting evidence must be distinguished cruel punishments and modes of putting to death by lingering tortures—mutilation, breaking on the wheel, burning at the stake, disembowelling, &c. (see EXECUTION). Notable instances of such were the tortures inflicted on the murderers of James I. of Scotland in 1437; on Damiens (q.v.), the would-be assassin of Louis XV. in 1757; and on Jean Calas (q.v.) in 1762. See also FLOGGING, PILLORY, STOCKS. Prison discipline was formerly little short of torture, including the use of bilboes and other dreadfully heavy irons; as also was the management of the insane; and the school punishments of comparatively recent times would now be regarded by many as falling under the same head. Powell's *American Siberia* (1892) describes a state of things in the convict-camps of the United States down till 1875 which may fairly be regarded as amounting to cruel torture—including the stringing of convicts up by their thumbs. The marvellous collection of instruments of torture (including the 'Iron Maiden,' resembling the 'scavenger's daughter') once used with hideous effect, and long on show as curiosities in Nuremberg, was bought by Lord Shrewsbury, and exhibited in London in 1891.

See INQUISITION, and works cited; WITCHCRAFT; BOOT, RACK, THUMBSCREW; Jardine, *Torture in the Crim. Law of England* (1837); Lecky, *Rationalism in Europe* (1865); Lea, *Superstition and Force* (Phila. 1866; new ed. 1878).

Toru Dutt, a young Christian Hindu girl of extraordinarily precocious genius, was born in Calcutta, March 4, 1856, studied French and English literature with avidity, spent the years 1869–73 in England and France, and at eighteen published a critical essay of strange maturity on Leconte de Lisle, with translations into English verse. She next gave herself to Sanskrit, and translated several portions of the *Vishnupurana* into English blank verse. In 1876 she published *A Sheaf gleaned in French Fields* (2d ed. Lond., with Memoir by her father, 1880), being English translations of about two hundred French poems. Next year she died, August 30, 1877. A romance which she had written in French, *Le Journal de Mdlle. d'Arvers,* was published at Paris in 1879, with a study by Mdlle. Clarisse Bader. Finally her *Ancient Ballads and Legends of Hindustan* was published at London in 1882, with a Memoir by E. W. Gosse.

Torula. See YEAST.

Tory (Irish *toiridhe,* 'a pursuer'), a name first given to certain bands of outlaws, half robber, half insurgent, who professed the Roman Catholic faith, and harassed the English in Ireland. It is used in this sense in Gayton's *Pleasant Notes upon Don Quixot* (1654), the Irish State Papers (1656), and R. Burney's *Kerdiston Dōron* (1660)—'Wilful peasants . . . degenerate into *torces* and moss-troopers.' About 1679, the time of the Popish Plot, it began to be applied as a term of reproach to the Cavalier or Court party, as supposed abettors of that trumped-up conspiracy. Oliver Heywood's *Diaries* (ed. by J. H. Turner, 1881) refer, under the date 24th October 1681, to 'the Ranters calling themselves Torys . . . an Irish title for outlawed persons,' which shows that the nickname was soon adopted by one of the two great political parties in Great Britain—the adherents, namely, of the ancient constitution of England without change, supporters of regal, ecclesiastical, and aristocratic authority; 'their prejudice,' said Dr Johnson, 'is for Establishment, while that of the Whigs is for Innovation.' As Whig (q.v.) has been largely superseded by Liberal, so, since 1830, has Tory been by Conservative (q.v.). Since 1880 it has a good deal revived, in the sense frequently of a non-conservative Conservative.

See Kebbel's *History of Toryism from Pitt to Beaconsfield* (1885); and Standish O'Grady's *Toryism and the Tory Democracy* (1886).

Tory Island, a small island, 2½ miles long, 9 miles off the north-west coast of Donegal, with a lighthouse, and a signal station (1890) connected by telegraph with Londonderry.

Totem, a natural object, not an individual, but one of a class, taken by a tribe, a family, or a single person, and treated with superstitious respect as an outward symbol of an existing intimate unseen relation. The Algonquin word is *otem,* which must always be preceded by the personal article, as *kit-otem* = the family-mark, *nind-otem* = my family-mark. Other dialects have different names, as the Iroquois *ohtara.* The wide distribution of Totemism among the nations of the Old World, civilised as well as savage, and its significance as at once a religious and a social system, was first pointed out by Mr J. F. M'Lennan in the article TOTEMISM in the first edition of this work (1868) and in a series of articles in the *Fort. Rev.* (Oct. and Nov. 1869 and Feb. 1870); the richest collection of data yet made is Mr J. G. Frazer's *Totemism* (Edin. 1887).

The totem is considered as helpful to the man, who in his turn abstains from killing it if an animal, or eating it if a plant, and who often assimilates himself to it by wearing its skin or the like, or tattooing its picture on his body. The whole members of the clan who have a totem in common count themselves of one blood, and claim the totem as their common ancestor. The restriction upon killing and eating it is absolute, and sometimes men are tabooed from touching or even looking at it under pain of death or expulsion from the tribe. Elaborate ceremonies connected with birth, marriage, and death point more closely to the identification of the man and the totem, and such ceremonies as those of the Australians at puberty are intended to initiate the youth into the restrictions that must be observed in sexual commerce. In Australia also we find special sex-totems, which it is forbidden the opposite sex to kill; and among the North American Indians special personal totems—*manitous*—which are usually revealed after the exhaustion of the long fast at puberty. Totemism thus forms the foundation of a vast social system of alternate obligation and restriction. It governs marriage and all sexual relations, for a man may not touch a woman of the same totem as himself. Sometimes the prohibition only extends to a man's own totem clan, but more frequently it includes several clans, in none of which is it allowed to marry. Such an exogamous group of clans within the tribe is a *phratry,* which was no doubt originally itself a totem clan that had since undergone subdivision. In Australia we find not infrequently a tribe divided into two phratries, each including a number of totem clans; sometimes sub-phratries again come between the phratries and the clans, still further by vexatious restrictions curtailing the liberty of marriage. But the allowable range of kinship may stretch over a thousand miles, and the native by no means needs spoken language to discover the women with whom he may have commerce, for the totem marks upon their bodies give him the plain indication of duty. For the significance of Totemism in rudimentary religion, see ANCESTORS (WORSHIP OF) and ANIMALS (WORSHIP OF); and for its importance on the social side, in laws of descent, whether through the male or female line, and in marriage, see FAMILY and MARRIAGE.

Mr J. F. M'Lennan, in his inquiry into the origin of Exogamy, concluded that it was based on an antecedent system of Totemism, evidence of which was generally found in all rude societies acknowledging kinship through women only, the same association being found almost as generally in those rude societies which know kinship through males, while the worship of plants and animals in more advanced societies acknowledging kinship through males was lineally descended from Totemism. Mr Donald M'Lennan (preface to *The Patriarchal Theory,* 1885) tells us that his brother had come to abandon his original theory as to the origin of Totemism, and that, in the final constructive work to have been completed had he lived, his aim was to have been rather to show its prevalence, to establish some leading points in its history, to exhibit it in connection with kinship and with Exogamy, and to make out its connection with worship. He tells us, further, that the general conclusion appeared to his brother to be that it was possible to demonstrate that, Totemism preceding Exogamy, the latter must have arisen in societies acknowledging no kinship save through women; that all other facts bearing on rude society may be interpreted as evidence of a gradual progress from the condition of which Totemism and female kinship are the mark; and that thus it was possible to exhibit the history of human society as that of an evolution moving with very various rapidity among different populations, but always beginning with a condition in which the idea of incest did not exist, and always tending upwards from that

condition. Whether or not this lowest step in the argument may be accepted—and grave objections enough will be found conveniently grouped in chap. xiv. of Westermarck's *History of Human Marriage* (1891)—the want of Mr M'Lennan's book is a loss to the science of Sociology that will not soon be made good.

Totila. See GOTHS, Vol. V. p. 323.

Totnes, a municipal borough and market-town of Devonshire, pleasantly situated on the slope of a steep hill on the right bank of the Dart, 29 miles SSW. of Exeter and 24 ENE. of Plymouth. The Dart is navigable to this point for vessels of 200 tons, and Brut the Trojan is fabled to have landed here: the 'Brutus Stone,' on which he first set foot, may be seen in the main street. At least, Totnes is a place of great antiquity, and retains two gateways, remains of the walls, a quaint guildhall, a good many antique houses, and an interesting Perpendicular church (1432; restored by Scott, 1874), with a noble red sandstone tower and a fine stone screen. The Norman castle of Judhael de Totnes, that crowns the hill-top, is represented by the circular shell-keep. There is a grammar-school (1568); and on the 'Plains,' near the river, stands a granite obelisk to the Australian explorer Wills, who was a native, as also was the Hebraist Kennicott. Incorporated by King John, Totnes returned two members till 1867. Pop. (1851) 4419; (1891) 4016. See works by W. Colton (1850) and Charles Worthy (2 vols. Exeter, 1889).

Toucans (*Rhamphastidæ*), a family of Zygodactyle Picarian birds, numbering more than fifty species, and inhabiting tropical America. They were formerly placed near the Hornbills (Bucerotidæ), which offer several points of analogical resemblance to them, and are often improperly called toucans in the East; but their nearest allies are now known to be the Barbets (Capitonidæ), one of which, *Tetragonops rhamphastinus*, strongly resembles a toucan in its coloration, &c.

Toucan (*Rhamphastos Toco*).

The toucans are divided into five genera: *Rhamphastos*, containing the typical species, has the bill most greatly developed, and the plumage mostly black, varied with white, scarlet, and orange; *Andigena*, containing the Hill Toucans, inhabiting the high forests of the Andes, and with a generally bluish-gray plumage; *Pteroglossus*, with smaller, long-tailed species, clothed in green, scarlet, and yellow plumage, and called Araçaris; *Selenidera* includes the Toucanets, which are very similar; the species of the last genus, *Aulacorhamphus*, are of a bright green colour. The legs of the toucan are strong, rather short, and with large scales; the toes are arranged in pairs, the first and fourth being turned backward. The form of the body is short and thick; the tail is rounded or even, varying in length in the different species from half the length to almost the whole length of the body, and is capable of being turned up over the body in a remarkable manner, which it always is when the bird is at roost. The neck is short and thick; the enormous bill is at the base of the full width and depth of the head, and is in some species more than half the length of the body. It is arched towards the tip, irregularly toothed along the margins of the mandibles, and extremely cellular and light, yet strong in structure. The tongue is very long, narrow, and singularly feathered on each side, the processes which give it this feathered appearance possibly adding to its sensibility as an organ of taste. When a toucan takes food between the points of the mandibles, the tongue is immediately applied to it, as if to test or enjoy it, and afterwards it is tossed into the throat by a sudden throwing back of the head. Toucans may almost be described as omnivorous; they eat fruits with avidity, but they also seize and devour small birds. Their powerful bill enables them to kill a small bird by a single squeeze. They make a curious clattering noise with their great mandibles, and also emit at times a harsh cry, sometimes resembling the word *tucano*, whence their name. They live chiefly in the depths of the South American forests, in small flocks, and lay two white eggs in the holes of trees. They are easily tamed, and bear cold climates well. In captivity they readily eat rice, bread, potatoes, eggs, and many other kinds of food. They are remarkable amongst birds for regurgitation of food, in order to a kind of mastication in the great bill, analogous to rumination in quadrupeds. The colours of the bill are, in most of the species, very brilliant during life, but disappear from stuffed specimens in museums. The largest species, as *Rhamphastos Toco*, are about two feet in length; the *R. Ariel* is the commonest species. See Gould's *Monograph* (2d ed. Lond. 1854).

Touch, the tactile sense, the least specialised of the senses. The sense-organs of the various groups of animals are discussed in the articles on the various groups. In the nervous system of man the organs of touch are (1) central end-organs (see BRAIN); (2) conducting nerve-fibres (see NERVOUS SYSTEM); and peripheral end-organs. Nerves end in the skin in two ways. In the simplest mode of termination they form a plexus in the dermis, pass outwards from this, lose their medulla, divide into fibrils, and are lost to view in or between the cells of the epidermis. Nerves end in this way in all parts of the skin, but the relative number of such terminations in different parts of the skin cannot be determined by present methods of research; they may be easily seen in the cornea. In the more complex mode of termination the nerves, retaining their medulla, end in the dermis in special structures of modified neurilemma and other cellular elements. These endings are of three sorts. (*a*) The *end bulbs* are round bodies 30 μ to 100 μ in diameter (μ is the diameter of a red blood-corpuscle), and of limited distribution, found in the conjunctiva, the lips, also in mucous membranes—e.g. on the tongue, the palate and elsewhere, and, slightly modified, in the sensitive parts of the genital organs; (*b*) *Touch corpuscles* are oval bodies 60 μ to 100 μ in long diameter, also of limited distribution, but most numerous in the papillæ of the dermis of the palmar surface of the hand, less numerous in the nipple of the breast, very scarce on under surface of the forearm, absent from the greater part of the surface of the body. It is estimated that on the tip of the forefinger there are 100 touch corpuscles for two square millimetres. (*c*) *Pacinian corpuscles* are larger bodies, 1 millimetre and more in length, like end bulbs, found in the subcutaneous tissue. There are about 600 in the under surface of each hand, and a few may occur in the back of the hand; they are numerous at the

joints, are found also on some periosteal nerves, and on the sympathetic nerves of the abdomen. From their distribution it is evident that they may or may not be essential to cutaneous sensibility. Indeed it seems that the touch corpuscles also are not essential to touch, for they are completely absent in certain parts of the body—e.g. the cornea—which are yet sensitive to pressure. Further, if those points of skin which are found by experiment to be peculiarly sensitive are cut out and examined, special nerve endings are not always to be found. Still the fact that as a general rule such endings are most frequent in areas of great sensibility compels the belief that they have some relation to that sensibility. The varying degrees of sensibility in the touch-organs are described at SENSATION, where also reasons are given for holding that the muscular sense is distinct from the tactile sense (see also SKIN, and TASTE). The functions of touch as a means of perception is dealt with at PSYCHOLOGY.—Touching for the king's evil is discussed at SCROFULA.

Touch-paper. See NITRE.

Touch-stone, a hard black stone, occasionally used in assaying. The original kind was a peculiar bituminous quartz or flinty slate obtained from Lydia in Asia Minor, and hence known as Lydian Stone; but black basalt may be employed. The process is explained at ASSAYING, Vol. I. p. 507.

Touch-wood is the wood of willows and some other trees softened by decay; Amadou (q.v.) is also so called. It is used as tinder, from the readiness with which a spark ignites it.

Toul, a fortified town in the French department of Meurthe-et-Moselle, on the Moselle, 20 miles W. of Nancy by rail. It has a former cathedral (965–1496), whose west front, with towers 245 feet high, is reckoned one of the finest in France, an 18th-century hôtel-de-ville, and manufactures of lace, hats, &c. The *Tullum Leucorum* of the Romans, Toul maintained a semi-independence till 1545; on 23d September 1870 surrendered to the Germans after an eight hours' bombardment; and since 1871 has been strongly fortified with a cordon of forts. Pop. (1872) 6584; (1891) 11,728. See works by Thiery (1841) and Daulnoy (1887).

Toulon, a seaport and naval arsenal of France, in the department of Var, stands on the shore of the Mediterranean, 42 miles ESE. of Marseilles and 564 SSE. of Paris. It lies at the head of a deep double bay, and rises towards the north in the form of an amphitheatre. The port is divided into two parts, the old and the new—the former, on the east, appropriated to merchant shipping, and the latter, on the west, surrounded by the dockyard, slips, arsenal, cannon-foundry, &c. The dockyard covers 240 acres; and belonging to the arsenal, which is perhaps the finest in France, are the sailyard, armoury, museum, &c. The fortifications were greatly extended after the conquest of Algeria (1830), Toulon becoming the chief port of communication with Africa; and important works of defence have been added since 1880. A cathedral, founded in 1096, the hôtel-de-ville, and a large theatre are the chief buildings. The climate is dry and bracing; but the older portions of the town are still unsanitary, and it suffered much from cholera in 1884. Pop. (1872) 69,808; (1891) 74,144. The Greek *Telonion* and Roman *Telo Martius*, Toulon suffered much from the Saracens, and first rose into importance as a naval stronghold towards the close of the 16th century. The English were defeated off here by the united fleets of France and Spain, 11th February 1744; and in 1793 Toulon was occupied for four months by the English (under Hood) and the Spaniards, who, however, were forced to evacuate the place after being fiercely attacked by the Republicans—a memorable siege as the first great achievement of Napoleon (q.v.). See Lambert's *Histoire de Toulon* (1886 *et seq.*).

Toulouse, an important city in the south of France, the capital anciently of Languedoc, and now of the department of Haute-Garonne, 160 miles SE. of Bordeaux and 466 S. by W. of Paris. It is situated in a broad and pleasant plain, on the right bank of the river Garonne, with the Canal du Midi sweeping round its eastern and northern sides. The Garonne is crossed here by a beautiful bridge (1543–1626), nearly 300 yards long, which connects Toulouse with the suburb of St Cyprien. The city, with the exception of the southern faubourg, is not particularly handsome (though the broad quays have rather an imposing appearance), nor has it many fine public buildings. One may note, however, the cathedral, containing the tombs of the Counts of Toulouse; the *Capitole*, or town-hall (1769); the church of St Sernin (11th to 15th century); and the Musée, with its interesting collection of antiquities, forming an almost uninterrupted chain in the history of art, from the Gallo-Roman to the Renaissance period. Toulouse is the seat of an archbishop, has a university academy, an academy of 'floral games' (*Société des Jeux Floraux*), claiming to date from a troubadours' contest in 1323, academies of arts, sciences, antiquities, &c., schools of law, medicine, and artillery, an observatory, botanic garden, and a public library of 60,000 volumes. Toulouse manufactures woollens, silks, leather, cannon, steam-engines, tobacco, brandy, &c., and carries on a great trade with Spain. Its liver and truffle pies are celebrated throughout the south of France. Pop. (1872) 114,025; (1896) 149,963.

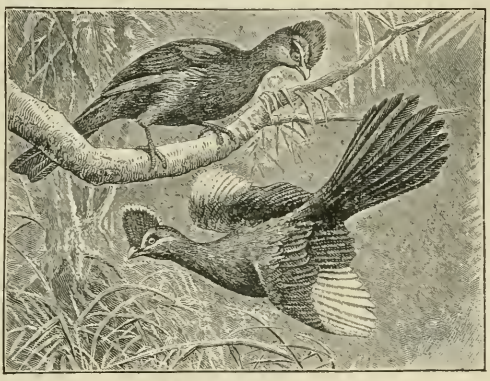
Tolosa was, in Cæsar's time, a city within the limits of the Roman *provincia*, and had been originally the capital of the Volcæ Tectosages, a Gallic tribe noted for its wealth and consequence. Under the empire its importance continued. Ausonius describes it as surrounded by a brick wall of great circuit, and so populous that it had founded four colonies. In 412 A.D. the Visigoths made it the capital of their kingdom (see GOTHS); and after the time of Charlemagne it was under the sway of counts, who made themselves independent about 920, but in 1271 the 'county of Toulouse' was reunited to the crown of France by Philippe *le Hardi*. Its literary celebrity reaches as far back as the Roman empire. Ausonius speaks of the *toga docta* of 'Palladian' Tolosa, and the favourite deities of the city were Jupiter, Minerva, and Apollo. At a neighbouring village a multitude of cinerary urns, statuettes, Phœnician, Celtiberian, Gallic, Greek, and Roman medals, fragments of buildings, and an entire paved street have been discovered. Early in the middle ages, under the Counts of Toulouse, it became a seat of Provençal poetry, and it suffered terribly in Simon de Montfort's pitiless papal crusade against the Albigenses (q.v.). The parliament of Toulouse had a great reputation, but unhappily it is likely to be best remembered by one of its most iniquitous decisions, that delivered in the case of the Calas (q.v.) family. In the battle of Toulouse (10th April 1814) the French under Soult were defeated by Wellington. Cujacius was born, and Fermat died, at Toulouse. The floods of 1855 and 1875 were specially disastrous.

See works by Aldeguier (1835) and Jourdan (1877), and *Toulouse: Histoire, Archéologie, &c.* (1887).

Toung-ngu, a town of Burma, on the Sittang River, 170 miles NE. of Rangoon by rail, and capital of a district of Tenasserim. Pop. 17,119.

Touraco (*Opisthocomus cristatus*), called also Hoatzin, Cigana, Gypsy, and several other names, a bird about the size of a pheasant, found in

Guiana and the Amazon region, and constituting the family Opisthocomidæ and order Opisthocomi. Wallace remarks that it has 'such anomalies of structure that it is impossible to class it along with any other family. It is one of those survivors



Touraco (*Opisthocomus cristatus*).

which tell us of extinct groups, of whose past existence we should otherwise, perhaps, remain for ever ignorant.' The most striking anomalies are the sternal apparatus, the divided muscular crop, and the reptilian character of the head of the unhatched chick. It lives in flocks on the lower trees and bushes bordering streams and lagoons, and feeds on various wild fruits, is never seen on the ground, and is nowhere domesticated. Its flesh is uneatable owing to its unpleasant odour.

See Bates, *The Naturalist on the Amazons;* Huxley, *Proceedings of the Zoological Society* (1868); Garrod, *Proceedings of the Zoological Society* (1879); Quelch, *In the Ibis* (1890). The name is also given to some of the quite different Plantain-eaters (q.v.) of Africa.

Touraine, one of the old provinces of France, of which the capital was Tours (q.v.), and which coincided with the department of Indre-et-Loire and a part of Vienne. See *Old Touraine*, by T. A. Cook (1892), and *La Touraine*, by Robida (1892).

Tourcoing, a frontier town of France, dept. of Nord, 10 miles NE. of Lille by rail, has manufactures of cloth, soap, beet-sugar, and machinery. Pop. (1881) 50,268; (1896) 73,353.

Tourguénieff. See Turgenief.

Tourmaline, a mineral which has a very complex and somewhat variable chemical composition. The chief constituents are silica and alumina in nearly equal proportions, and forming about three-fourths of the whole. The remainder consists of boracic acid, ferrous oxide, manganous oxide, magnesia, lime, soda, potash, and lithia, which are not all present, however, in any specimen. Tourmaline has a hardness = 7 to 7·5, and is thus harder than quartz, but not so hard as topaz. Its specific gravity is 2·94 to 3·3. It crystallises in rhombohedral forms, which are usually hemihedral, the prisms being often triangular or six-sided, and variously acuminated. The mineral has a vitreous lustre, and varies from transparent to opaque. The most common colours are black, brownish black, and bluish black; blue, green, and red varieties also occur; but white or colourless kinds are rare. Red tourmaline is known as *rubellite;* pale blue or bluish black as *indicollite;* Berlin-blue and transparent as *Brazilian sapphire* (in jewellery); green and transparent as *Brazilian emerald, chrysolite,* or *peridot of Brazil;* honey-yellow as *peridot of Ceylon;* colourless as *achroite;* black as *schorl.* Tourmaline occurs frequently in drusy cavities in granite, and also as an accessory mineral in granite, gneiss, and many crystalline schists, as also in certain granular dolomites and crystalline limestones associated with schists and plutonic rocks. Not infrequently it occurs along with various precious stones in the sands and alluvia derived from the disintegration of plutonic rocks and crystalline schists, as in Ceylon, Siberia, and Brazil. Various kinds are found in the Shan districts of Burma. The finest tourmalines are much valued by jewellers, but are comparatively rare. The black variety, *schorl,* is common in many of the granites and schists of Britain.

Tournament, a military sport of the middle ages, in which combatants engaged one another with the object of exhibiting their courage, prowess, and skill in the use of arms. Spectacles of this kind seem first to have become common in France, whence the usage spread to Germany and England, and afterwards to the south of Europe. A tournament was usually held on the invitation of some prince, who sent a king-of-arms or herald through his own dominions and to foreign courts. The intending combatants hung up their armorial shields on the trees, tents, and pavilions round the arena for inspection, to show that they were worthy candidates for the honour of contending in the lists in respect of noble birth, military prowess, and unspotted character. The combat took place on horseback, or at least was always begun on horseback, though the combatants who had been dismounted frequently continued it on foot. The usual arms were blunted lances or swords; but the ordinary arms of warfare, called arms *à outrance,* were sometimes used by cavaliers who were ambitious of special distinction. Tournaments were the subject of minute regulations, which in some degree diminished their danger. The prize was bestowed by the lady of the tournament on the knight to whom it had been adjudged, he reverently approaching her, and saluting her and her two attendants. The period when tournaments were most in vogue comprised the 12th, 13th, and 14th centuries; and the place where the most celebrated English tournaments were held was the tiltyard near St James's, Smithfield, London. The church at first discountenanced tournaments, some of its decrees prohibiting persons from engaging in them under pain of excommunication, and denying Christian burial to a combatant who lost his life in one. The church seems, however, to have looked with more favour on these combats after the middle of the 13th century. During the 15th and 16th centuries tournaments continued to be held; and no better conception of a tournament can be gained than from the account of the combat at Stirling in 1448 between the knight-errant Jacques de Lalain and the Master of Douglas (Hume Brown's *Early Travellers in Scotland,* 1891). But by 1500 the alteration in the social life and warfare of Europe had changed their character, and they are rather to be regarded as state pageants than as real combats. The death of Henry II. of France, in 1559, consequent on a lance piercing his eye at a tournament, led to their general abandonment, both in France and elsewhere, and there have been few attempts to revive them even as mere spectacles. The progress of firearms helped also to put them out of fashion; but tournaments still took place in the reign of James I., and at the Hague in 1633 the Prince of Orange held a 'passage of arms,' in which Prince Rupert 'carried away the palme.' A magnificent entertainment consisting of a representation or imitation of the old tournament was given at Eglinton Castle in August 1839, by the thirteenth Earl of Eglinton: Lady Seymour was the Queen of Beauty, and many of the visitors enacted the part of ancient knights; among them

Prince Louis Bonaparte, afterwards Napoleon III. —According to Ducange, the difference between a tournament and a joust is that the latter is a single combat, while in the former a troop of combatants encounter each other on either side. But this distinction has not been always observed.

Tournay (Flemish *Doornik*), a town in the Belgian province of Hainault, on the Scheldt, near the French frontier, 35 miles WSW. of Brussels. Its splendid Romanesque cathedral, 400 feet long, has five towers and pictures by Jordaens, Rubens, and Gallait; and there are also the churches of St Quentin and St Brice (with the grave of King Childeric), the belfry (1190), and a bronze statue (1863) of the Princess d'Épinoy, who in 1581 valiantly defended Tournay against Parma. Although one of the oldest towns in Belgium, it has quite a modern appearance, with fine suburbs and beautiful broad streets. The chief manufactures are hosiery, linen, Brussels carpets, and porcelain; but there are few large workshops, most of the fabrics being executed by the people in their own houses. Pop. (1880) 32,566; (1891) 35,403. Tournay, the ancient *Tornacum* or *Turris Nerviorum*, was in the 5th and the beginning of the 6th century the seat of the Merovingian kings, subsequently belonged to France, but in 1526 was included in the Spanish Netherlands. During May 1794 it was the scene of several hotly contested fights between the French and Austro-English armies, the most important of which was that of the 19th May, in which Pichegru beat the Duke of York. Fontenoy (q.v.) is 5 miles SE.

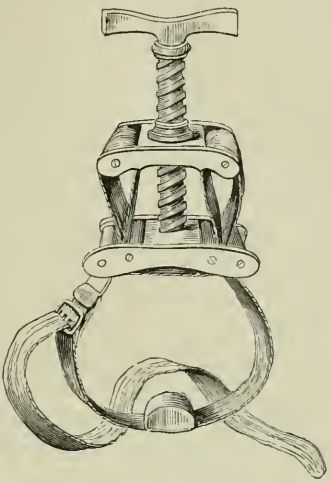
Tournefort, Joseph Pitton de (1656–1708), botanist, was born at Aix, travelled in Greece and elsewhere, and died professor in the Collège de France. His botanical system maintained its ground till the time of Linnæus, and his principal works were *Institutiones Rei Herbariæ* (1700) and *Éléments de Botanique* (1694).

Tourneur, Cyril, a dramatist, who flourished at the close of the reign of Elizabeth and the beginning of that of James I., but of whose history absolutely nothing is known beyond the fact (*Acad.* May 9, 1891) that he had seen service in the Low Countries, and died in Ireland, leaving his widow destitute, February 28, 1626. In 1600 he published his *Transformed Metamorphosis* (discovered in 1872), a satirical poem, obscure in expression, and marred, moreover, by pedantic affectations of style; in 1609 he issued a *Funeral Poem* on Sir Francis Vere, in 1613 an *Elegy* on Prince Henry. But his fame rests alone on two plays, the *Revenger's Tragedy*, licensed and printed in 1607, and the *Atheist's Tragedy*, printed in 1611, but undoubtedly written the earlier of the two. The plot of the latter is poor, though the versification is free and flowing; but when we turn to the *Revenger's Tragedy* we are at once arrested by its tragic intensity, the condensed power of passion, the fiery strength of phrase, the cynical and bitter mockery. The plot is an entangled web of lust and blood in which the dramatist moves with a mastery of the elements of tragic passion that brings him abreast of Webster, the closest of the followers of Shakespeare in one—but that not the greatest—of his moods. Tourneur's power has not escaped the unerring insight of Lamb and Hazlitt. Mr Fleay (*Biographical Chronicle of the English Drama, 1559–1642*) thinks the *Revenger's Tragedy* the work of the author of the *White Devil*.

The only complete edition is that of J. Churton Collins (2 vols. 1878), with a good critical introduction; the two plays are printed, together with Webster's *White Devil* and *Duchess of Malfi*, in the 'Mermaid' series, with an introduction by J. A. Symonds (1888).

Tourniquet, an instrument for compressing the main artery of the thigh or arm, either for the purpose of preventing too great a loss of blood in amputation, or to check dangerous hæmorrhage from accidental wounds, or to stop the circulation through an aneurism. For the last purpose special forms of tourniquet are required, which do not compress the whole limb.

The common tourniquet consists of three parts—viz. (1) a pad to compress the artery; (2) a strong band which is buckled round the limb; and (3) a bridge-like contrivance over which the band passes, with a screw whose action raises the bridge and consequently tightens the band. The best kind of pad is a small firm roller bandage, about an inch thick; it must be placed lengthways over the main artery so as to compress it against the bone, and must be secured in its place by a turn of bandage, over which the band of the tourniquet must be applied. This band must first be tightly buckled, and the pressure must be then quickly increased to the necessary extent (viz. till the circulation through the limb is completely arrested) by the action of the screw, which should always be opposite the buckle of the band.



Common Tourniquet.

The credit of the invention of this most useful instrument is usually ascribed to the French surgeon Morel, who, in 1674, used a stick passed beneath a bandage, and turned round so as to twist it up to the requisite degree of tightness, as a means of preventing the undue loss of arterial blood in amputations of the limbs—a rough but by no means ineffectual form of tourniquet, which may often be usefully extemporised in cases of emergency at the present time (see Vol. I. p. 702). Mr Young of Plymouth, in 1679, described a similar apparatus. A much improved screw tourniquet was invented by Petit in 1718, the same in principle as that described above. Many surgeons now use in preference a strong elastic band, wound two or three times round the limb—a method first introduced by Esmarch.

Tours, capital of the department of Indre-et-Loire, as it formerly was of the province of Touraine, stands in the fertile valley of the Loire just above the influx of the Cher, and is 147 miles SW. of Paris by rail. It is a regularly built and handsome town, nearly divided in half by the Rue Nationale. Conspicuous amongst its buildings is the noble cathedral, in various styles of Gothic from the 13th to the 15th century, the two towers (partly modified Renaissance) being 205 feet high. The glass is very fine. Other buildings are the church of St Julien, the towers and other remains of the famous abbey church of St Martin (long a place of pilgrimage, but destroyed at the Revolution), the archbishop's palace, palais de justice, museum, public library, &c. Near the town are the remains of the monastery of Marmoutier, and of the castle of Plessis les Tours, the favourite

residence of Louis XI. (see *Quentin Durward*). There are some well-preserved ancient houses, including that of the executioner Tristan l'Hermite. Near Tours are many of the fine old chateaux for which Touraine is famous. There are fine statues of Descartes and Rabelais. Tours has a brisk trade, manufactures woollens and silk, does much printing, &c., and is famous for its plums and similar confections. Pop. (1872) 43,368; (1891) 60,335. The Roman *Cæsarodunum*, Tours was both earlier and later capital of the Turones (whence the modern name). Near it Charles Martel (q.v., Vol. III. p. 115) won the great victory that saved northern Europe from the Saracens. Meetings of the States-general and councils repeatedly took place here. The great silk manufactures of Tours, established in the 15th century, were destroyed by the Revocation of the Edict of Nantes (1685), which drove into exile nearly half of the most industrious inhabitants of the place. During the Franco-German war Tours was the seat of government from the time the Germans closed round Paris till (21st September) they in like manner closed round and then occupied Tours. St Martin and Gregory of Tours have separate articles. There are works on the city by Giraudet (1874) and Grandmaison (1879).

Tourville, Anne Hilarion de Cotentin, Count de, was born at the chateau Tourville, near Coutances, 24th November 1642. Entering the French navy, he became, though of delicate health, almost immediately conspicuous for bravery and enterprise; and his early services in wars against the Turks and Algerines established his reputation. In 1677 he fought against the combined fleets of Spain and Holland. In the war which broke out after the English revolution of 1688, between France on the one part and England and Holland on the other, Tourville was put at the head of the French navy. In June 1690 he entered the English Channel with a powerful fleet, and inflicted a disastrous and ignominious defeat on the united English and Dutch armament near Beachy Head. Tourville ranged the Channel unopposed; and on 22d July his fleet cast anchor in Torbay. In 1692, Louis XIV. having resolved to invade England on behalf of James II., an immense fleet was assembled at Brest under Tourville in order to protect the descent. On the 16th May of this year the French fleet was descried from the cliffs of Portland, and on the following morning the English and Dutch force stood out to give battle. From the morning of the 19th to the afternoon of the 24th raged one of the greatest naval battles of modern times, that of Cape La Hogue (see Tactics, Naval, p. 44). It ended in the complete defeat of the French, sixteen of their men-of-war being utterly destroyed. In spite of this disaster Tourville was graciously received at Versailles, as having maintained the honour of his country, and was made a Marshal of France. Sailing from Brest harbour in the spring of this year, he attacked an English merchant fleet under inadequate convoy, and succeeded in inflicting a damage on English traders estimated at some millions sterling. Sir George Rooke, who commanded the convoy, had some difficulty in saving his own squadron from destruction. This was the last exploit of the great French admiral; he died at Paris, 28th May 1701.

The *Mémoires* published in his name (1758) were not genuine. See Macaulay's *History;* and Delarbre, *Tourville et la Marine de son Temps* (1889).

Toussaint l'Ouverture (a surname added for his bravery in once making a *breach* in the ranks of the enemy), one of the liberators of Hayti, was born a slave in 1743, joined the negro insurgents in 1791, and at length in 1795, for his services against the Spaniards, was made by the French Convention general of brigade, in 1797 general of division, and a little later chief of the army of San Domingo. Soon after he cleared the British and Spaniards entirely out of the island, quickly restored order and prosperity, and about 1800 began to aim at independence of France. Bonaparte having, after the peace of Amiens, proclaimed the re-establishment of slavery in San Domingo, Toussaint declined to obey, whereupon General Le Clerc was sent with a strong fleet to compel him. The liberator soon submitted, but was treacherously arrested, sent to France, and flung into a damp, dark dungeon at Fort de Joux, near Besançon, where he sank after ten months, April 27, 1803. See his own *Mémoires* (1853), and Lives, also in French, by Saint-Rémy (1850), Gragnon-Lacoste (1877), and Schœlcher (1889).

Tow, the coarse or broken part of flax or hemp separated by heckling. See Linen.

Tower. See Campanile, Spire, and the articles on the various styles of architecture.

Tower Hamlets, originally certain parishes, hamlets, and liberties without the jurisdiction of the city of London, and once within that of the lieutenant of the Tower; now a 'parliamentary borough' or division of London, lying to the east of the City and Finsbury. Till 1885 it sent two members to parliament; since then it falls into seven electoral districts, each of which returns one member. The divisions are those of Whitechapel, St George's-in-the-East, Limehouse, Mile-End, Stepney, Bow and Bromley, and Poplar (see London, p. 703).

Tower of London. See London, p. 702.

Town-council, the governing body of a municipality. See Borough; also Alderman, Bailie, City, Mayor, Municipality, Provost.

Townshend, Charles, Viscount Townshend, statesman, was born in 1674, of a very old family, at Raynham in Norfolk. His father, Horatio, had been a prominent Presbyterian, but, having been one of the most forward in restoring the monarchy, was by Charles II. made Baron in 1661, and Viscount in 1682. He died in 1687, when Charles was only eleven years old. He, when of age to take his seat in the Upper House, entered public life as a Tory, but soon afterwards became a disciple of Lord Somers, and cordially co-operated with the Whigs. He was named by the Godolphin administration one of the commissioners for arranging the Union with Scotland; was joint-plenipotentiary with Marlborough at the Hague; and negotiated with the States-general the Barrier Treaty, which pledged the States-general to the Hanoverian succession, and England to procure the Spanish Low Countries for the United Provinces, as a barrier against France. Dismissed from his places in 1712, on the formation of the Harley ministry, Townshend maintained a close correspondence with the court of Hanover, and obtained the entire confidence of George I., who, while still at the Hague, on his way to his new kingdom, made him Secretary of State. With Stanhope he formed a ministry entirely Whig, in which Walpole, his brother-in-law, soon became Chancellor of the Exchequer. The principal act of the government was the passing of the Septennial Bill (1716); that same year saw Townshend's dismissal. After the bursting of the South Sea Bubble, and the deaths of Sunderland and Stanhope, Townshend (1721) again became Secretary of State. But he was no longer the acknowledged leader of the Whigs. The superior talent of Walpole, his financial abilities, and his influence in the House of Commons caused a change in the relative position

of the two ministers, and converted those who had been so long friends and colleagues into rivals and enemies. After Townshend had somewhat precipitately made the treaty of Hanover between England, France, and Prussia, an open and unseemly quarrel broke out between them. Walpole said he thought the firm should be Walpole & Townshend, not Townshend & Walpole; so it was, and Townshend retired into private life in 1730. He introduced the turnip into Norfolk from Germany, greatly improved the rotation of crops, steadily refused to reappear in public life, and died 21st June 1738. See works on Walpole, and Stanhope's *History*.

Townshend, CHARLES, wit, orator, and statesman, was second son of the third Viscount Townshend, and grandson of the foregoing. He was born 29th August 1725, and entered the House of Commons in 1747 as a supporter of the Pelham (Whig) administration. His first great speech was against the Marriage Bill in 1753. Upon the dissolution of the Whig government the Earl of Bute gained him by the offer of the post of Secretary at War; but on Bute's resignation in 1763 he was appointed First Lord of Trade and the Plantations—the versatility of his political career obtaining for him the appellation of 'the Weathercock.' In the Chatham ministry of 1766 he accepted the post of Chancellor of the Exchequer and leader of the House of Commons. When Lord Chatham in a distempered state of mind abdicated the post of first minister, Townshend manifested the greatest vanity, ambition, and arrogance. Finding the notion of an American revenue agreeable to the court, and not unpalatable to the House of Commons, he proposed and carried those measures of taxation of commodities in America that led to the separation of the American colonies. Townshend's wife was created a peeress, and he was about to be entrusted with the formation of a ministry when he was carried off by a putrid fever, 4th September 1767. The difference between his contemporary reputation and his fame is very striking. He was ranked as an orator with Pitt. Burke called him 'the delight and ornament of the House of Commons.' Macaulay speaks of him as 'the most brilliant and versatile of mankind,' who had 'belonged to every party and cared for none.' Earl Russell describes him as 'a man utterly without principle, whose brilliant talents only made more prominent his want of truth, honour, and consistency.' See his Life by P. Fitzgerald (1866).

Township, or VILL, the oldest proprietary and political unit of the Germanic races, an organised self-acting group of families exercising ownership over a definite area, the mark. The oldest English manors are conterminous with townships: the parish, a later division than the township, and originally purely ecclesiastical, is assumed to be equivalent to the township if there is no evidence to the contrary. In fact many parishes, especially in the north of England, consist actually of but one township; but generally they comprise more than one, and are subdivided into townships, hamlets, 'tithings,' 'boroughs,' or the like, none of which subdivisions, unlike the parish itself, has ever had a church or a constable of its own. For administrative purposes the township is subordinate to the Parish (q.v.).—In the United States the word is variously used (1) of a subdivision of a county; (2) the corporation composed of the inhabitants of such area; or sometimes (3) of municipal corporations only less fully organised and with fewer powers than a city.

Towton, a township in the West Riding of Yorkshire, where was fought, near Tadcaster (q.v.), one of the chief battles in the Wars of the Roses (q.v.).

Toxicology, the science of poisons, embraces the physical and chemical history of all known poisonous substances, the methods of testing for them, their action on the living body, the *post-mortem* results which they occasion, and (according to some writers) the medical treatment that should be adopted. See POISON.

Toynbee, ARNOLD, the second son of Joseph Toynbee, a famous aural surgeon, was born in London, August 23, 1852. From his father he acquired a taste for poetry and pictures. His early acquirements were mostly in the direction of modern literature and philosophy. He spent two years at a military college, but left on finding that he had mistaken his profession. During the four years he spent at Oxford he became a prominent figure amongst an attached circle of students, studied political economy, and read in a miscellaneous fashion. 'Most men,' he said, 'seem to lose their religious beliefs in passing through the university; I made mine.' He came under Ruskin's influence, did some practical work in road repairing, read his Bible diligently, and the Imitation. On taking his degree he became tutor to a number of young men who had passed the Indian Civil Service examinations, and who were further preparing themselves for their work at Balliol College. Endowed with the gift of fluent speech, he began to address audiences of working-men; and believing that the poor could only be adequately helped by those who had lived amongst them and felt their needs, he took up residence in Commercial Road, Whitechapel, in 1875, and associated himself with the religious work carried on there by the Rev. S. A. Barnett. His health gave way under his unwearied labours, and the noise, dullness, and dreariness of his surroundings, but from the inspiration of his example and teaching during this period sprang the idea of Toynbee Hall. He died in 1883, owing to overstrain following on two lectures directed against Henry George's *Progress and Poverty*. A course of lectures delivered at Oxford between 1881–82 on the economic history of England, along with other popular addresses, was published in 1884 under the title of *The Industrial Revolution*, with Memoir by Jowett. Toynbee was frank and unreserved, of transparent sincerity, had a keen sympathy with the life of the labouring classes, and was a close student of history. The residence house known as Toynbee Hall was organised in Commercial Street, Whitechapel, as a memorial to Toynbee in January 1885, under the direction of the Rev. S. A. Barnett. It partakes somewhat of the nature of both a college and a club, the idea being to connect the memorial of Toynbee with the study of 'political economy in its social aspects, to which he devoted the scholar half of himself, and with his work among the artisan population of our great cities, to which he gave the other, the missionary half.' This is carried out by the members of the universities of Oxford and Cambridge who find residence there, who strive 'to provide education and the means of recreation and enjoyment for the people, to inquire into the condition of the poor, and to consider and advance plans calculated to promote their welfare.' During the first four years there were fifty-four residents.

Toys. The most primitive toy of most abiding interest for children is the Doll (q.v.), already dealt with. But toys are of infinite variety, and the making of them forms a very important industrial occupation. Large numbers are made in London, Birmingham, and other places in Britain; but by far the greater number in Germany and Switzerland. Nuremberg is especially important in this respect. Squibs, crackers, &c. are somewhat dangerous toys (see PYROTECHNY), and there are

many other ingenious applications of chemistry which combine amusement, instruction, and risk—e.g. the so-called Pharaoh's Serpents (see SULPHOCYANATES), &c. A valuable use of what may be called toys is made in the Kindergarten (q.v.).

Tracadie, a fishing-town on the east coast of the Canadian province of New Brunswick, 35 miles E. of Bathurst, with a hospital for lepers—the chief lazaretto of Canada. Pop. 2000.

Tracery, the beautiful forms in stone with which the arches of Gothic windows are filled or traced for the support of the glass. These forms vary with every variety of Gothic architecture, from the simple early forms to the Decorated (q.v.) and Flamboyant (q.v.). See WINDOW, PERPENDICULAR, CHAPTER-HOUSE, &c.

Trachea, or WINDPIPE, that part of the air-passages which lies between the Larynx (q.v.) and the bronchi (see RESPIRATION). It is very rarely affected by disease of independent origin, though often secondarily by extension of laryngitis from above, or of bronchitis from below.

Foreign bodies occasionally pass through the larynx into the trachea. In cases of this kind the patient who has had some foreign substance in his mouth which is supposed to have been swallowed is seized with a convulsive cough, threatening suffocation, but subsiding after a time. The symptoms that then ensue vary with the weight and figure of the substance, and according as it is fixed or movable. A large and very irregular body may be impacted in the trachea, and may thus more or less obstruct the respiration on both sides of the chest; and this obstruction will probably soon be increased by the inflammatory products that are excited. A small heavy object will usually pass through the trachea into one of the bronchi (usually the right), or one of its branches, obstructing respiration to a less extent. While a foreign body remains in the air-passages there is always more or less risk of suffocation, though a piece of bone has been coughed up after sixty years in that situation. The attempt to remove it, however, has also risks; and inversion of the obstructing object, which is commonly resorted to, should not be tried unless tracheotomy either has been performed, or can be done at a moment's notice. If attempts at removal are unsuccessful the foreign substance may become encapsuled and quiescent; but it more often sets up organic lung disease (pneumonia, gangrene, &c.).

TRACHEOTOMY.—The air-passages may be opened in several different situations—viz. through the thyroid cartilage (*thyrotomy;* only used for removal of growths, &c.); through the crico-thyroid membrane (see LARYNX; *Laryngotomy*); through the cricoid cartilage and the upper rings of the trachea (*Laryngo-tracheotomy;* very rarely used); and through the trachea, either above or below the isthmus of the thyroid gland (*Tracheotomy* proper, *high* or *low*, according to the part chosen). Laryngotomy is more quickly and easily performed, especially in adult males, and is less dangerous; tracheotomy is a more difficult, tedious, and dangerous operation, but in some cases (as, for example, where there is any necessity for introducing the forceps) must be selected. It is unnecessary to enter into details regarding the modes of performing these operations. When the operation is completed a large curved double tube to breathe through is inserted in the aperture, and the outer tube is secured round the neck with a tape. The inner tube should fit quite loosely into the outer, so that if it becomes obstructed it may have a chance of being ejected by the patient's cough, and that it may be readily removed and cleaned. The tube may be removed in a few days, or may have to be worn permanently. Tracheotomy may be required for cut throat, laryngitis and other laryngeal disease, croup, diphtheria, tumours or epithelial growths in the larynx, foreign bodies below the glottis, or external tumours (bronchocele, abscesses, &c.).

Trachyte, a crystalline igneous rock, generally grayish in colour, sometimes brown, yellow, green, or red. It is usually a fine-grained or compact rock, more or less markedly porphyritic. The essential constituents of trachyte are sanidine (felspar), of which the rock is chiefly composed, and one or more of the ferro-magnesian bisilicates—biotite, augite, and hornblende; various other minerals may be present. The rock has often a rough or harsh feeling (Gr. *trachys*, 'rough'), due to the abundant presence of minute vapour or gas pores, or to angular cavities. Trachyte occurs both in the form of lava-flows and as intrusive sheets, dykes, and masses, and ranges from early Tertiary times to the present. See IGNEOUS ROCKS.

Tractarianism is named from the ninety *Tracts for the Times*, published at Oxford in 1833–41. The principal writers were Pusey (q.v.), Newman (q.v.), Keble (q.v.), Hurrell Froude, and Isaac Williams. See also ENGLAND (CHURCH OF).

Traction-engines are usually steam locomotives dragging carriages behind them on ordinary roads; but the term may be here extended so as to include the steam-carriages for conveying passengers—attempted as early as the end of the 18th century (see below)—and the newer types of motor-cars.

Auto-cars or *Motor-cars* (Fr. *voitures automobiles*) of various patterns attracted much notice in France in 1894–97. Some of them were propelled by electricity, with storage batteries (see DYNAMO-ELECTRIC MACHINES, ELECTRIC RAILWAY), but the majority by some form of oil-engine (see GAS-ENGINE, p. 109). In Britain various locomotive acts, due to fear of accidents through the frightening of horses, had been imposed from 1861 to 1879, and seriously impeded progress in the use of road locomotives. Thus every such vehicle, besides paying a license of £10, required to have two persons in charge of it, and a man to go in front with a red flag; the speed even on country roads must not exceed 4 miles an hour, &c. Since November 1896, vehicles weighing, when not laden, less than 3 tons are exempted from these restrictions. Those weighing less than 1½ ton may go 12 miles an hour; from 1½ to 2 tons, 8 miles; over 2 tons, 5 miles. They must be able to back, must have a bell, and must not emit smoke or visible vapour. Generally the carriage resembles a horse-drawn carriage, is guided by a handle-bar, and has levers to vary the speed. In 1900 a 1000 mile trial run from London to Edinburgh and back occupied 11 days actual travelling; and 20 cars successfully completed the trial.

Steam-carriages.—It was to the conveyance of passengers by steam that all the plans of early inventors were devoted, and at the present day interest in them is chiefly historical. The main idea in all cases was to fit an engine and boiler to an ordinary carriage or coach. The boiler, usually carried at the back, was of some form possessing strength with little weight, and capable of rapidly raising steam; the engine also, either at the back or under the coach, usually worked a cranked axle, and the main axle carrying the two driving-wheels was driven from this by chain gearing; most of them ran on four wheels, though some had a fifth wheel as a steerer. Cugnot, a Frenchman, made a steam-carriage in 1769; it ran at 2¼ miles per hour, and carried four persons; a capsize in a street in Paris led to the imprisonment of the inventor, and put a stop to further trials. Murdock in 1782, Watt in 1784, Symington in 1786, and others made

models, but the first one which actually ran in England was made by Trevithick and Vivian in 1803. This attained a speed of 8 or 9 miles per hour in the streets of London; but want of encouragement and difficulties produced by bad roads compelled Trevithick to turn his inventive faculties into other fields of work. Improvements in the main roads led to a great revival of interest about 1830, and during the years 1827–34 numerous more or less successful steam-carriages were built; one made by Sir Goldsworthy Gurney ran for three months in 1831 with passengers between Cheltenham and Gloucester, while Hancock's steam-omnibuses (carrying 14 to 16 passengers) ran pretty constantly during the years 1833–36 in London, and attained often a speed of 10 or 12 miles per hour; some of his coaches ran long journeys, such as from London to Brighton; he was in fact the most successful of all these inventors. Scott-Russell also constructed and ran in 1834 six steam-coaches between Glasgow and Paisley. However, the great opposition placed in their way by road trustees, and the gradual spread of railways, led to the abandonment of all these schemes, and practically nothing further has been done (see TRAMWAYS). In 1891, however, Serpollet patented an ingenious and successful steam-carriage with a flattened coil boiler; superheated steam is used, and the engine is very economical. But the majority of the various patterns of motor-cars for roadways made in the decade 1890–99 used electricity or gas-engines rather than steam.

Traction-engines for heavy loads.—The main difficulty with which builders of these engines have to cope has been the driving-wheels, the tires of which must be able to resist the great wear and tear and violent shocks caused by passing over bad roads or uneven ground, and must at the same time possess considerable adhesive powers, since the resistance to motion even on good macadamised roads is more than eight times as great as it is on rails. Boydell, who made the first successful engine in 1856, used a series of flat segments of rails, so jointed round the circumference of the driver that the engine ran, as it were, on an endless tramway; it was an extraordinarily noisy, clattering, unmechanical contrivance, still it gave great adhesion, and enabled his engines to drag heavy loads over exceptionally soft ground. A little later Bray brought out a wheel with rigid tires, fitted with short strong spikes projecting from the rim (these could be withdrawn when not wanted); this, again, had considerable adhesion, but was very destructive to the roads. R. W. Thomson of Edinburgh, in his so-called 'road-steamers,' adopted flexible india-rubber tires; the driving-wheels were light wrought-iron drums about 15 inches wide, with a flange at the sides; round the drum was stretched an india-rubber band 5 inches thick and 12 inches wide, protected on the outside with a flexible sheath of thin steel plates. This tire had the great advantage that it formed a perfect spring for the engine, and, flattening under the pressure, it gave a broad tread, and so increased enormously the adhesion; on paved roads with a gradient it had much better hauling power than any engine with rigid tires. The objection to the use of such tires is their heavy cost (those of the 'Ravee,' a road-steamer for service in India, cost £241), and the expense of renewals; they were, however, very successful, being employed in Glasgow and other towns hauling heavy castings, boilers, &c. from the workshops to the wharves. All these types and many others are now practically obsolete. The modern engine usually has rigid wheels, the rims are either cast-iron or wrought-iron, with diagonal wrought-iron cross strips riveted to them. Another kind of wheel, a good deal used, has rims of cast-iron with cells about 6 inches in the side, in which are placed hard-wood blocks, projecting a little beyond the rim (an india-rubber pad between the block and the bottom of the cell acting as a spring); this gives a broad, flat tread, good adhesion, and does not damage the roads. The traction-engines now in use run on four wheels, the hind pair being drivers, the front pair steerers; the boiler is of the locomotive type, working usually at about 130 lb. steam pressure; the engine and attached parts are carried on the top of the boiler, cylinder at forward end, crank-shaft at firebox end. Motion goes from the crank-shaft to the driving-axle through steel spur-wheel reducing gear carried by other shafts. A differential compensating bevel gear is usually fitted, one driving-wheel being then loose on its axle; this enables the engine to turn corners without straining the axles. Springs are also now usually fitted, though their use somewhat complicates the method of supporting the gearing between the crank-shaft and driving-wheel axle; these, however, greatly reduce the shocks in passing over bad roads. Most of the engines now made have a winding-drum, which enables steep gradients to be overcome; the engine itself proceeds to the top of the incline, then a steel rope attached to the wagon carrying the load is gradually wound up on the drum, thus hauling up the load. To obtain increased power, the engines sometimes have two cylinders, and are also made compound; a stock of coal is carried in a bunker behind the foot-plate, and water in a tank under it. These engines are now most extensively used, and are much cheaper than horse traction; in one case the cost has been given as 2d. per ton per mile, including depreciation and interest on capital; where the roads are kept in good order they do no damage. The great obstacles to their more extended use were the legal restrictions in force till 1896. All locomotives for road use are liable to a carriage duty of from 15s. to £2, 2s., and after January 1897 to an additional duty of from £2, 2s. to £3, 3s., according as they weigh, not laden, less or more than 2 tons; the special license is not exacted for light locomotives.

Agricultural locomotives are essentially portable engines, fitted with various methods of self-propulsion—in some cases by pitch-chains, more usually by spur-gearing. They are much lighter in make, though otherwise very similar to traction-engines; they are employed mainly in drawing loaded wagons, thrashing-machines, &c. from farm to farm; by disconnecting the propelling gear and blocking the wheels, they can be used as stationary engines to drive by belting off the flywheel, with which they are always fitted, thrashing-machines, fans, and other farm plant. Fowler's steam-ploughs are locomotive; they are able both to pay out and wind up the steel rope moving the plough to and fro, and also to shift themselves along the field. Traction-engines are now made by all the chief firms of agricultural implement-makers (see Vol. VIII. p. 245); to the late Mr T. Aveling of Rochester, much of the present success of steam road-traction is due. In making macadamised roads, the rolling of the broken metal is now done by heavy steam-propelled rollers very similar in design to traction-engines.

Tract Society. In the 17th century several traces are found of associations for printing and promoting the sale of religious works, but none of them seems to have existed long. The 'Society for Promoting Christian Knowledge,' founded in 1701, had for one of its objects 'the dispersion, both at home and abroad, of Bibles and tracts of religion.' In 1750 was formed 'The Society for Promoting Religious Knowledge among the Poor,' not, like the former, confined to the Church of England, but embracing Christians of all denominations.

The Religious Tract Society (1799) originated with the Rev. George Burder (q.v.). Its beginnings were humble, but it soon expanded; its income, from sales of publications and contributions of benevolence, including a small balance from the previous year, amounted in 1891 to £201,119, 5s. 5d., and the total expenditure, in trade and grant departments, to £199,444, 14s. 10d. In the same year 678 new publications were issued, 113 of which were tracts; the issue of books, tracts, &c. from the foundation of the Society until 1891 was 2,830,763,810. Its operations have extended over all quarters of the world, and it has issued books and tracts in 204 languages and dialects. The business of the Society is conducted by a committee chosen annually, which consists of four ministers and eight laymen, and six trustees. Half the number are members of the Church of England and the other half Nonconformists. It has produced many new works, reprints, and abridgments, and has half-a-dozen thriving periodicals, such as the *Leisure Hour*, *Sunday at Home*, *Boy's Own Paper*, and *Girl's Own Paper*. The number of separate tracts, books, &c. in the Society's catalogue is about 4000. Within recent years its publishing area has been much extended, and now the catalogue embraces works in many departments of literature, competing with, and approaching closely to, the class of productions emanating from houses conducted by private enterprise.

Trade, Board of, a department of government more correctly designed 'The Lords of the Committee of Her Majesty's Privy-council appointed for the Consideration of all Matters relating to Trade and Foreign Plantations.' In 1660 Charles II. created two separate councils for Trade and for Foreign Plantations, which in 1672 were consolidated into one. The Board of Trade and Plantations, after being abolished in 1675, and reappointed in 1695, was again abolished in 1782. In 1786 the presently existing department was established by Order in Council, being a permanent committee of Privy-council for the consideration of all matters relating to Trade and the Colonies. The board consists of a president, together with the Lord Chancellor, the Archbishop of Canterbury, the First Lord of the Treasury, the principal Secretaries of State, the Chancellor of the Exchequer, the Speaker of the House of Commons, and others. But of the latter *ex officio* members none take part in the work of the board, which is managed by the president and his staff; the staff includes the permanent and parliamentary secretaries, four assistant secretaries, and a chief of the statistical department. The board is now divided into five departments: (1) the statistical and commercial department, (2) the railway department, (3) the marine department, (4) the harbour department, and (5) a financial department. Since 1864 the presidentship has always been held by a cabinet minister. Before 1867 there was a vice-president who was a member of the administration, though without a seat in the cabinet.

The functions of the Board of Trade are partly of a ministerial, partly of a judicial kind, and have of late years been greatly enlarged by a variety of statutes. The board is charged with the general superintendence of all matters relating to the mercantile marine. It requires and considers reports made to its inspectors and other officers, and orders returns of various kinds regarding trade and navigation. It is empowered to make regulations regarding the examination and qualifications of applicants for the position of master or mate of passenger-ships. Under the Merchant Shipping Act, 1854, it grants licenses to persons to engage or supply seamen or apprentices for merchant-ships, decides on claims for wages, and investigates charges of misconduct and incompetency. It also appoints officers to inquire into and report on the condition of steam-vessels.

The supervision of railways and railway companies, both as to their original formation and their working, constitutes an important part of the duties of the Board of Trade. Railways were first subjected to government control by an act of 1840 which conferred power on the Board of Trade to appoint inspectors of railways, to approve or disallow bylaws, to require returns of traffic, and to decide disputes between connecting lines. Further powers have been added by subsequent acts. In 1846 the increase of these duties, arising from the rapid extension of railways, led to the transfer of this department of the Board of Trade to a separate board created exclusively for the management of railway business; but in 1851 this latter board was abolished, and its powers were retransferred to the Board of Trade. Notices of applications for railway acts with plans are required to be deposited with the board before any bill can be introduced into parliament; and before any railway can be opened for traffic the permission of the board must be obtained on the report of an inspector. On the occurrence of an accident notice must be given to the board, which sends an inspector to inquire into the circumstances, and on his report the board is empowered to take what steps are judged necessary for the security of the public.

Many matters relating to the interests of trade which come before other departments are referred to the Board of Trade for information or advice. Thus there are frequent communications with the Foreign Office regarding the negotiation and working of commercial treaties, and with the Treasury regarding alterations in the customs.

A statistical department of the board was established in 1832, whose province is to collect and publish tables containing classified information regarding the revenues, population, commerce, wealth, and moral and economical condition of the United Kingdom and its dependencies, to prepare a selection from the statistics of foreign countries, and a monthly account of trade and navigation. All applications made to the Queen in Council by companies or private persons for charters of incorporation are referred to the Board of Trade; and among the functions committed to it by statute are the registration of joint-stock companies and copyright designs, and the supervision of proceedings under the Bankruptcy Act, 1883. The board is empowered by several local and personal acts to control the proceedings of the commissioners for regulating the employment of coal-whippers and the discharge of coal-laden vessels in the port of London. In 1853 the Department of Science and Art, which owed its origin to suggestions made in the Second Report of the Commissioners for the Exhibition of 1851, and was at first a department of the Committee of the Privy-council on Education, was placed under the control of the Board of Trade; but in February 1856 it was retransferred by an Order in Council to the Education Department. Since 1886 the department issues monthly the valuable *Board of Trade Journal*, containing extracts from consular reports, customs regulations and changes of tariff, a report on the state of the skilled labour market, and much information of value to the mercantile community.

Trade Corporations. See Corporation, Company, Guilds, Livery.

Trade-marks. A trade-mark is the name or mark under which any one trades. It is a mode of connecting certain goods in the mind of the public with a particular manufacturer or seller; and its function is to give to a purchaser a satisfactory

assurance of the make and quality of the article he is buying. A trade-mark is the property of the person legally adopting it, and he has a right —antecedent to and independent of the various trade-mark acts—to prevent any one else from using it to his prejudice.

Water-marks on paper, dating from the 14th century, are among the oldest trade-marks. Trade-marks appear to have become a prominent feature in the industrial life of England in the early part of the 18th century. The law relating to them has pursued the following course of development. (1) At first no *right of property* in a trade-mark was recognised, and only the *actual, fraudulent, and injurious* use by one person of the mark of another was restrained and punished. This rule, which originally prevailed both at common law and in equity, was inspired by the old judicial dislike of patent privileges and the failure to see the essential difference between a patent and a trade-mark. (2) In 1838, however, in the case of Millington *v.* Fox (3 My. and Cr. 338) Lord Chancellor Cottenham granted a perpetual injunction against the defendant, although no intentional fraud was established. Since that time the Court of Chancery has uniformly interfered to prevent the infringement of trade-marks on the principle of protecting property alone, and it has not been necessary for the plaintiff to prove that the defendant invaded his rights intentionally. (3) The Courts of Common Law did not imitate the wise liberality of the Court of Chancery, and down to 1873 proof of fraud on the part of an infringer was of the essence of a common-law action for damages. The Judicature Act of 1873 provided, however, that in any conflict between the rules of law and of equity the latter should thenceforth prevail; and if actions of infringement were still tried in the Queen's Bench Division, there can be little doubt that the equitable rule would be applied, and proof of fraud dispensed with. (4) But under the judicature acts and the rules of the supreme court trade-mark cases are brought in the Chancery division, so that the former variance between the Courts of Common Law and the Court of Chancery has now only a historic interest and importance. The owner of a trade-mark that is being infringed usually applies for an *interlocutory* injunction to restrain the immediate infringement, and at the same time brings an action in which he claims (*a*) a *perpetual* injunction, and (*b*) an account of the profits made by the infringer, or damages in lieu thereof. The fraudulent imitator of a trade-mark may be indicted for false pretences, but not for forgery. See, however, Merchandise Marks (*infra*).

The Registration of Trade-marks.—At common law a trade-mark could be acquired only by actual user; it must have been 'so applied in the market as to indicate to purchasers that the goods to which it was attached were the manufacture of a particular firm.' By the Trade-marks Registration Act, 1875, a Register of Trade-marks was established at the Office of the Commissioner of Patents (now the Patent Office), and it was provided that the registration of a trade-mark should thenceforth be equivalent to public user. This provision is in substance repeated in the Patents Acts, 1883–88, by which the registration of trade-marks is now regulated. The registration of a person as proprietor of a trade-mark is *primâ facie*, and after five years is conclusive, evidence of his right to the exclusive use of the said mark (subject to the provisions of the acts); and no person can institute proceedings for infringement unless the mark alleged to be infringed has been registered, or—in the case of marks in use prior to the Act of 1875—has been declared by the certificate of the Comptroller-general to be non-registrable. For the purposes of the acts a trade-mark must contain at least one of the following essential particulars: (*a*) a name of an individual or firm printed, impressed, or woven in some particular and distinctive manner; or (*b*) a written signature or copy of a written signature of the individual or firm applying for registration thereof as a trade-mark; or (*c*) a distinctive device, mark, brand, heading, label, or ticket; or (*d*) an invented word or words; or (*e*) a word or words having no reference to the character or quality of the goods, and not being a geographical name. There may be added to any one or more of these 'essential particulars' any letters, words, or figures, or combination thereof; but the applicant for registration of any such additional matter must in his application state the essential particulars of his trade-mark and disclaim any right to the exclusive use of the added matter. But a person need not disclaim his own name or the foreign equivalent thereof; and any special and distinctive word or words, letter, figure, or combination thereof used *separately* and as a trade-mark prior to the Act of 1875 is still registrable. A trade-mark when registered may be assigned and transmitted, but only in connection with the goodwill of the business concerned in the particular goods or classes of goods for which it has been registered, and is determinable with that goodwill. The provisions for the rectification of the Register noticed in the article PATENTS apply *mutatis mutandis* to trade-marks. The 'International Convention for the Protection of Industrial Property'—the history of which is given in the same article—also extends to trade-marks. Under that convention an applicant for registration of a trade-mark in any one of the contracting states may obtain protection in any of the other contracting states by application there within three or, in the case of countries beyond the seas, four months from the date of the first application. The subsequent application is antedated to the date of the first, and is consequently not defeated as otherwise it might have been by prior user in the protected interval. In the United States there is a good deal of difference between the laws of the various states on this subject.

Merchandise Marks.—Under the Merchandise Marks Acts, 1887–94, which apply to England, Scotland, and Ireland, every person that (*a*) forges, (*b*) falsely applies to goods, (*c*) makes, disposes of, or has in his possession any instrument for forging any trade-mark, or (*d*) applies any false trade description to goods is liable, on conviction on indictment, to a maximum period of two years' imprisonment, and on summary conviction to a maximum term of four months' imprisonment with hard labour, or a fine of £20, for the first offence, and in the case of a second or subsequent offence to a term not exceeding six months with hard labour, or a fine of £50. Any person aggrieved by the decision of a court of summary jurisdiction may appeal to quarter sessions. It is a competent defence to a prosecution under the act that the defendant took all reasonable precautions against committing the offence, and gave on demand by, or on behalf of, the prosecutor all the information in his power, or otherwise acted innocently. The limitation for proceedings under this act is the expiration of the three years next after the commission, or the one year next after the discovery of the alleged offence, whichever shall first happen. A conviction under this act does not relieve the defendant from liability to *civil* proceedings.

See works by W. H. Browne (2d ed. Boston, 1885), R. S. Mushet (1887), L. B. Sebastian (3d ed. 1890), J. S. Salaman (1891); and Lawson on the Patents, Designs, and Trade Marks Acts (Patent Office Inquiry, 1887).

Trade Protection Societies are associations composed of merchants, tradesmen, and others, which have been formed for the promotion of trade and for protecting the individual members from losses in their business transactions; one of the earliest being the 'London Association of Guardians for the Protection of Trade,' established in 1776. In 1871 the Board of Trade granted a license for incorporation to one under the Companies Acts, 1862-67. The operations of these societies used to be confined chiefly to the compilation of registers of bankruptcies, insolvencies, and private settlements with creditors. Each member informed the secretary of the name, occupation, and address of the customers who became insolvent, with the amount of dividend their estate yielded; and latterly, whether the insolvency was due to recklessness and extravagance, or was innocent misfortune. Special attention was directed to the exposure of swindlers and persons who had been guilty of fraud or embezzlement. The information accumulated in the registers, though always accessible to such members as made inquiry at the offices of the society, was kept strictly private from all others. But the extraordinary development of commercial enterprise which took place in the early part of the 19th century added a new stimulus to the trade protection movement. The registers which the societies now printed and circulated among their members contained transcriptions from the following public records—viz. the records of the bankruptcy courts, registers of assignments and trust-deeds, bonds or warrants of attorney, bills of sale, judges' orders, protested bills, and decrees in absence. The societies also undertook to recover past-due bills and accounts for their members, to investigate the circumstances connected with bankruptcies and insolvencies, collect dividends, and perform the general agency business of their members—the whole being done under the direction of a committee appointed for this purpose. Committees were also appointed to scrutinise all measures affecting trade and commerce which might be introduced into parliament, and to promote legislation favourable to the commercial interest. The sphere of action of trade protection societies thus rapidly widened. The older societies established offices and branches throughout the country; new societies sprang up in the large provincial cities, which in their turn opened agencies and branches in other towns and villages; and the various societies being in communication, the machinery of the whole is available for the purposes of each. In 1852 the various societies formed themselves into an association, which now includes upwards of sixty societies. An annual meeting of delegates from all these is held in London, at which matters affecting trade are discussed.

Tradescantia, a genus of American perennial herbs, differing much in habit, which comprises some thirty-two species, four belonging to the United States, and some tropical. The flowers are loosely or densely panicled, and resemble umbels. *T. virginica* is often cultivated in gardens, and *T. discolor*, a white-flowered evergreen, under glass. The genus was named after John Tradescant, gardener to Charles I., who died in 1638.

Trade Unions, or TRADES UNIONS. It is now almost universally admitted that trade unions are the lineal descendants of, and the legitimate successors to, the old English guilds, more especially in their latest development, that of craft Guilds (q.v.). History is almost silent as regards the guild system from the time of the suppression of the guilds, in the reign of Henry VIII., until the later attempts of the handicraftsmen in the 18th century to establish trade customs having the force of law, and to enforce the provisions of the Statute of Apprentices, which in a sense was a kind of codification of the then existing guild law, as formulated in the Ordinances of the Guilds, and held to be binding in nearly all trades. Those ordinances were kept alive in various ways, sometimes by charters granted in the reign of the Stuarts, as in London, at Exeter, Norwich, and other towns, where manufactures were carried on, and at Berwick-on-Tweed and other places where, with or without a charter, the old system was recognised and applied to existing industries. Trade unions arose out of the contests, legal and otherwise, to enforce the trade customs established by the guilds, and the provisions of the Statute of Apprentices, 5 Eliz. 4, and of other statutes subsequently passed and in force. In the newer industrial developments of the 17th century, and their fuller expansion in the 18th, some of those provisions were regarded by employers as being in restraint of trade, and they tried to evade them, or to ignore them. The workmen endeavoured to maintain and enforce them; hence arose 'combinations,' mostly of a temporary character in the first instance, to protect the interests of the workmen, and exact obedience to the law. By degrees those combinations became more and more permanent, until, towards the end of the 18th century, the trade union was instituted in a more or less crude form, but similar in most respects to those now in existence. Among the earliest complete types of a trade union is perhaps the 'Institution,' established by the cloth-workers of Halifax in the year 1796; but others had existed at a much earlier date.

Copyright 1892 in U.S. by J. B. Lippincott Company.

The earlier history of trade unions is one long record of repression. Amongst other things inherited from their predecessors the guilds was the suspicion that they were opposed to public policy; they were regarded as combinations in restraint of trade, as the supporters of industrial monopoly, and as dangerous associations which ought to be suppressed. The Combination Laws were passed to prohibit them, and other laws were resorted to for the purpose of destroying their power. Perhaps the very persecution to which they were subjected helped to give them permanency as an institution in the land. This policy was reversed in 1824, and by the amending Act of 1825, by the repeal of the Combination Laws. But the then legal recognition did not afford to them legal protection. It was not until 1869 that they obtained protection for their funds and property by a temporary act, and only permanently in 1871 by the Trade Union Act. Since that date other acts have placed them upon a footing of equality with other voluntary associations in the country.

In the first twenty years of the 19th century many trade societies were formed, some few of which have survived to this day. The earliest survivors date from about the year 1809, but they have undergone changes in constitution, if not much in their aims. So active were those unions in the years 1818, 1819, and 1820 that inquiries were instituted into their constitution and operations, which inquiries paved the way for the ultimate repeal of the Combination Laws, the prosecutions which had taken place helping rather than retarding the movement for repeal. The unions were extremely active from 1824 to 1838, when a further inquiry was instituted. They were most active in 1833 and 1834, and again in 1847 and 1848. In the year 1850 a new departure commenced by the formation of the Amalgamated Society of Engineers, one of the most perfect types of a trade union in the world.

In their essential character trade unions are

voluntary associations of workmen for mutual protection and assistance in securing generally the most favourable conditions of labour for their members. Voluntary they must of necessity be, for the freedom to combine implies also the freedom not to combine. Within certain lines the law limits and defines what may and what may not be done, in furtherance of the objects of a trade union. Briefly stated, the position is this: Neither employer nor workman has the right to compel another person to do, or abstain from doing, that which he deems best for his own advantage. Formerly a trade unionist was liable to prosecution and punishment for doing certain things that another person, not in a trade union, might do. Now the law is fairly equal as between man and man, irrespective of his belonging or not belonging to a trade union.

The main object of a trade union is the securing of the most favourable conditions of labour in the particular trade it represents. This fundamental object includes all efforts to raise wages, and to maintain wages at the highest possible level in the trade; the reduction of the hours of labour, and resistance to any increase in those hours; and also the regulation of apprentices, overtime, piecework, methods of employment or discharge, and modes of working generally. All those objects are now lawful, provided that the means adopted to enforce them are legal; formerly they were all regarded as unlawful, being in restraint of trade, a doctrine rendered obsolete by the Acts of 1875.

The constitution of a trade union is essentially democratic. The members are bound by a code of rules presented to each of them on being admitted as members. Those rules are revised from time to time by the votes of the members, either by a plebiscite or through delegates, popularly elected, by the votes of members, by ballot or in open lodge. The old notion of bylaws other than the rules is now exploded. A large proportion of the unions are now registered, a process which would render bylaws illegal were they of the character formerly supposed. The bylaws are merely lodge regulations for the conduct of business, of no public concern whatever.

Opinions differ widely as to some of the trade objects of trade unions, especially as to apprentices, overtime, piecework, and the like. The apprenticeship system is abandoned in many trades, in so far as admission to the union is concerned. In some unions, however, the system prevails, the ostensible object being to secure good handicraftsmen; but there can be little doubt that it is intended, as was intended by the Ordinances of the Guilds and by the act of Elizabeth, to limit the number of workers at the particular trade. As to overtime, opinions have greatly changed of late, the general feeling being in favour of restriction in that respect. As to piecework, it is as much in favour in some trades as it is repugnant to the workers in others; the adoption of it is regulated mainly by the nature of the employment. In some industries it is the universal practice, in others it is only partially resorted to, in others it is deemed to be inapplicable. The union regulates time-wages in the one case and piece-rates in the other, either by a scale, a log, or a price-list. With respect to the hours of labour the uniform action of the unions is in favour of shorter hours, according to the trade. Only since 1887 has any demand sprung up for an equal day of eight hours for all workers, a demand not seriously entertained by the majority.

These and other objects are termed the trade purposes of the union. In practice they vary in their application to the particular trade. In some the question of apprentices never crops up; it is inapplicable at the present time, whatever it might have been formerly. Overtime mainly pertains to day-workers, though long hours apply equally to piece-workers; but shorter hours, when obtained, apply alike to all, though the modes of apportionment may differ. The work of a trade union which has to regulate a price-list, or maintain a scale, is often of a most laborious and minute character, as in the tailoring trade, in the boot and shoe trades, and more especially in the textile trades, the latter requiring experts of a high character to be able to work out the 'statements.' In all cases the object is to maintain the standard of wages at the highest level possible, making such advances as the conditions of trade will permit, and resisting reductions where the members and their officials deem it expedient to do so.

Generally speaking, the means by which trade unions seek to attain their objects is strikes. Formerly this was the only means; but the growth of the unions, their recognition by law, and the diminution of the prejudices which existed against them, have enabled the officials and the executives of the associations to approach employers by boards of conciliation and arbitration, thereby averting strikes. Moreover a system of self-adjusting sliding scales has been devised, especially in the iron and steel and coal trades, by means of which the rates of wages vary with the price of the material, rising or falling as prices advance or recede. In such cases there is a minimum wage fixed as a basis, the percentage being arranged according to certain customs in the trade. In the event of a strike it is usual to recognise trade customs, such as giving notices where notices are required; the union that sanctioned a strike without giving such notices would gain little sympathy and no support from other unions if appealed to for help—unless indeed there were very strong and urgent reasons for not doing so. In cases of arbitration it is extremely rare for any union to contest the award of the arbitrator, although there have been instances of the kind. They are, however, so few in number, compared with loyal acceptance, even when the award is against the men, that it is unfair to allege that the unions do not loyally abide by the decision of an umpire as a general rule. It was at one time usually urged that the cost of a contest was greater than the advantages that could possibly accrue, even if successful. This position is untenable; and were it true, as alleged, men would soon cease to strike. Strikes are indeed most costly, and they usually involve a large amount of suffering and privation, but on the whole the balance of profit is with the aggregate men of the trade, even if it be sometimes at the cost of the strikers. The reasons are obvious. The battle is fought by a few, the many share the advantages, whatever they may be. Strikes are deplorable, and there is a growing disposition to avoid them as much as possible, though passion gets the better of reason sometimes, and disputes occur where they might have been averted.

The growth of trade unionism is a feature of the times in which we live. Only a very few years ago trade unions were tabooed by all sorts and conditions of men, other than the men in such trades who had experienced the advantages of such unions. A large proportion even of those fought shy of them. Now they are quite fashionable; they are commended in the senate, in the pulpit, from the platform, and in the press, until the workers begin to feel a sense of shame in not belonging to one. Even clerks and civil servants, who used to deride them, have some kind of association for mutual protection. They are spreading and extending in all directions. They have been recommended by a committee of the House of Lords as the best mode of dealing with 'Sweating' (q.v.). It is

certainly no longer a reproach to belong to a trade union, for their trusted officers are members of parliament, have had, and have, seats on royal commissions, have been accredited as British representatives at an imperial congress, have been entertained by the heir-apparent to the crown, and fill posts of honour in many of the local institutions of the land.

It is not quite so easy to accurately describe the actual increase of membership, because no absolutely reliable record exists of their real numerical strength throughout the country at given dates. The Registrar's returns will not furnish the figures for the simple reason that all the unions are not registered, and some that are do not always send in returns. Nevertheless the gradual growth since 1871 is indicated by the increase in membership of the registered societies that regularly make returns as to the number of members, income and expenditure, and the amount of funds. At the close of 1872, the first full year of registration, the total number of registered trade unions was 73, with 217,128 members; in 1891 there were 490 registered societies, with a total of 645,451 in the 235 societies sending in returns. In Scotland only 1 society failed to make returns, in Ireland 13, and in England and Wales 241 failed to comply. It is estimated that there are about 2000 trade societies in the United Kingdom, with a total membership of nearly 2,250,000, and having an aggregate balance in hand of about 2 millions sterling, the annual income being nearly equal to that amount. The weekly contributions of members vary according to the objects included in the society's rules. In trade unions established for trade purposes only the contributions range from 2d. or 3d. per week to 6d. per week, with from 3d. to 6d. per quarter for local objects or branch expenses. In the unions having provident benefits as well as trade purposes, the contributions range from 6d. to 1s. per week, the small quarterly payments being a trifle higher in most instances. These regular payments are exclusive of levies, special and general, sometimes amounting to a total sum equalling a year's contribution. But this is exceptional. The total payments by the members of the Amalgamated Society of Engineers, and some other unions similarly constituted and with like benefits, amount to quite £3 per annum, often more. The average amount per member in the total of the registered societies making returns amounted in one year to £2, 2s. 9d., and that year was not the worst for trade; but the average of the aggregate societies would not, as a rule, greatly exceed £1 per member. The average over ten years for all the registered societies making returns was £1, 3s. 5d. per member.

The principal difference between one trade union and another is to be found in the benefits provided for the members under the rules. There is no essential difference in constitution and aims. All have for their primary object 'trade protection,' and consequently provide strike-pay. A few, and more particularly some of the new unions, make no further provision. But the vast majority of those established for trade purposes only provide 'funeral allowance,' a provision directly inherited from the old guild system. The most perfect types of the modern trade union are those which provide what are called 'provident benefits,' such as weekly payments to members out of work, during sickness, and superannuation in old age; accident benefit, in cases of partial or total disablement; funeral allowance, in case of death of member or his wife, and, in some cases, insurance against loss of tools, and benevolent grants in times of acute distress; all of which benefits are in addition to, not in lieu of, strike-pay. The amounts payable under these several heads vary considerably—from 8s. to 12s. per week to members out of work; from 9s. to 15s. per week in sickness; from 5s. to 10s. per week superannuation; from £6 to £15 in case of death; from £50 to £100 in cases of accident; from £5 to £10 loss of tools by fire, &c.; and from 10s. to 25s. per week in cases of strikes. The latter amounts are often increased by special levies, or by the voluntary contributions of other societies, or by public subscriptions.

The advantages conferred upon the members of societies making such provident provisions are so enormous that the wonder is that all trade unions have not made similar provision, at least to the extent of ability of the members to contribute such sums as will assure the benefits. It is the provident side of trade unions that has reconciled the public to their legal recognition, and has enabled the legislature to legalise and protect them. The extent of those benefits, and their far-reaching effects, are evidenced by the fact that in forty years thirteen societies have paid in provident benefits alone to their members £7,460,071, while the total strike-pay by the same societies during the same period amounted only to £481,816. Yet those societies are pre-eminently the unions that have secured and maintained for their members the highest rates of wages, the shortest hours of labour, and the best conditions of employment enjoyed by any industrial workers in the country. The total income in 1890 exceeded £550,000 for the thirteen societies, and their expenditure exceeded £500,000; nevertheless the total balance in hand exceeded £750,000. The staying power of such unions is immense, for the whole aggregate funds may be used in a labour struggle in case of need. There is, however, very slight prospect of such vast expenditure being required, as the moral and material force of such large accumulations exercises a potent influence in preventing and averting strikes.

The economical effect of those benefits and of the accumulated funds for their sustenance is great beyond all question. Hunger competition is averted because the members are supported when out of work, during sickness, and in old age. Starvation wages are not possible in such cases; the only question is what standard of living shall the members aspire to and endeavour to attain. Prudence is inculcated in this connection, for the members will hesitate to run inordinate risks, however tempted to do so. Strikes are fewer in those societies than formerly, albeit they are stern and stubborn when they occur. The history of such unions is one of continuous progress, in numbers, in resources, and in influence. Other societies have maintained their ground in numerous instances, but not progressively in the same ratio. Many have collapsed, revived again, and once more collapsed; but in no case have the provident unions failed to keep their engagements with their members, although in a few they have undergone an immense strain in times of trade depression.

As before stated, there is really no essential difference between the old and the new trade unionism. The new unions are formed mainly on the old lines, and many are verging more and more towards the best modern type. The newer unions were in the first instance constituted as societies for trade purposes only, thus going back to the earlier and simpler forms of industrial organisation. Their leaders rather ostentatiously declared that they were 'fighting machines,' and sneered at the 'huge benefit clubs,' as they termed the Amalgamated Society of Engineers and similar associations. Already some of these new unions have introduced funeral benefits, a few superannuation allowance, others accident benefit, but none of them either out-of-work or sick benefits. In their modes of action the newer unions have been more aggressive,

less tolerant of opposition, more inclined to use force or compulsion as regards non-unionists, and they are also rather more reckless in the initiation of strikes. This was inevitable, for a strike is the *raison d'être* of a union that is merely a fighting machine. In times of industrial excitement and disputes men will readily subscribe and vote money from a sentiment of *esprit de corps*, being impelled by the action of others, by the enthusiasm engendered, and the pressure brought to bear. These incitements over, the influences removed, the battle lost or won as the case may be, the fervour is gone, apathy sets in, and the contributions fall away. There are not the same impelling forces at work as in the provident unions—where the motive and incentive to continuous contributions are operating without cessation, because of the permanent benefits in store for each individual member. The new unionists also rely more upon possible legislation for labour than the older unionists.

Trade unions are no longer under the ban of the law. Their action is approved by living political economists. Their influence is felt, and their intervention is recognised by all classes of society, by the state, by employers, and by the general public. Differences of opinion exist as to the methods and the means, and also the objects in some instances. If well organised, wisely directed, and powerful by reason of membership and resources, they command attention, and are able to equalise the conditions of labour in the manner suggested by Adam Smith. They protect their members by placing them in a position to exact mutuality in all labour contracts. The present conditions of labour in Britain furnish incontestable proofs of their useful work, whatever may be said of their action in particular instances. But the full measure of their worth, as industrial organisations, is only to be seen in the operation of their provident benefits. They keep their own poor, succour and support their own sick, provide for the aged and infirm, bury their own dead, and render important assistance in cases of accident, adversity, loss of tools, and other ills that especially fall to the lot of the poor. They do this without the taint of pauperism, thus preserving the self-respect of the members and of their families. They also afford assistance, often of a generous character, to other similar bodies of men or associations in cases of need. Their influence is also very largely educational, they inculcate thrift, they promote sobriety, they discourage profanity and bad language, and they teach and enforce discipline, order, and obedience to law. Their growth recently has been phenomenal: the engineers have 86,500 members; the Northern Counties Association of Weavers, 81,000; the Miners' Federation of Great Britain, 250,000; and many other unions from 20,000 to 65,000, with incomes proportionate to their numbers.

The Trades Union Congress was established in 1868, and meets annually in different towns. In the first year 118,367 members of trade unions were represented; in 1888, 674,634; and in 1900, 386 delegates represented 140 organisations, with 1,225,133 members. Since 1894 the delegates, which till that time included also representatives of trades councils, have only represented fully-paid-up members of trade unions. They discuss all questions relating to labour, and have a standing parliamentary committee to look after matters which may affect their interests in parliament. In January 1899 a special congress met to discuss, and finally approved of, proposals for the formation of a General Federation of Trade Unions, the objects being to uphold the right of combination of labour, to improve the status of workers, to secure unity of action among all societies forming the federation, to promote industrial peace and take all amicable means to prevent strikes, and to establish a fund for mutual assistance and to carry out the foregoing objects. The Miners' Federation has also an annual congress; the delegates at the 1900 meeting represented 150,000 men from all parts of Great Britain except Northumberland and Durham.

Comparatively little progress has been made in the institution of trade unions on the continent of Europe, but some progress is now being made. Up to a recent date the associations were political rather than industrial; in England it is the reverse. The effect of the international labour congresses has been to familiarise the workmen of Germany, France, Belgium, Holland, Austria, Italy, Switzerland, and even Spain with the essential principles of industrial organisation, and some excellent types of the modern trade union have been established. What is now required is that there shall be freedom to combine in all countries as in England.

In the United States there are labour organisations, such as the Knights of Labour (q.v.), &c., but the secret system, at one time their prominent feature, has been discarded. The best unions in the States are the branches of the Amalgamated Society of Engineers, the Carpenters and Joiners, and a few others. The government takes cognisance of the movement through the Department of Labour.

In the British colonies the best unions are in the Australian colonies, in some of which excellent unions exist. Here the engineers and the joiners have been the chief pioneers. But the Australians are far ahead of all other colonies, and even of the United States, in industrial organisation, the unions being modelled after those in England, usually those of the best type.

See the articles GUILDS and works there cited, FACTORY ACTS, FRIENDLY SOCIETIES, and LIABILITY OF EMPLOYERS; Comte de Paris, *The Trades Unions of England* (trans. 1869); Thurlow, *Trades Unions Abroad* (1871); Lord Brassey, *Work and Wages*, and other works on the labour question (1872–80); Stanley Jevons, *The State in Relation to Labour* (1882); Thorold Rogers, *Six Centuries of Work and Wages* (1884); Brentam, *The Relation of Labour to the Law of To-day* (New York, (1891); *Handy Book of the Labour Question* (1876); *Conflicts of Capital and Labour* (1878; 2d ed. 1890); *Trade Unionism New and Old* (1891), by the present writer; *The History of Trade Unionism*, by Sidney and Beatrice Webb (1894); publications of the Labour Bureau established in 1866; Reports of Committees on combination of workmen, sweating, and of the Royal Commission (1867–69), and of the Labour Commission (1891–92).

Trafalgar', CAPE, a low promontory on the south coast of Spain, about 29 miles west-north-west of Tarifa (q.v.), on the Straits of Gibraltar. It is memorable for the great naval victory obtained (October 21, 1805) by the British fleet under Nelson over the combined fleets of France and Spain under the French admiral Villeneuve and two Spanish admirals. The British force consisted of 27 sail of the line, 4 frigates, 1 schooner, and 1 cutter; the force of the French and Spaniards united amounted to 33 sail of the line, 5 frigates, and 2 brigs. Villeneuve formed his fleet in a double line in close order, Nelson attacked in two lines, Collingwood leading the first. His own ship, the *Victory*, ran on the *Redoutable* with the intention of breaking the line, and soon forced her to strike, but not before Nelson had been mortally wounded by the fire kept up from her tops. Nelson lived long enough to know that twenty of the

enemy had struck. The English loss was 1587 men. See NELSON; and Professor Laughton's *Story of Trafalgar* (1890).

Tragacanth (Gr., 'goat-thorn'), a name given to several low spiny shrubs of the genus Astragalus (*A. gummifer*, *A. microcephalus*, &c.), found in western Asia, and to the mucilaginous substance or gum derived from them—for which see GUM.

Tragedy. See DRAMA.

Tragopan (*Ceriornis*), a genus of birds in the Pheasant family, represented by five species in India and China. They are birds of very beautiful plumage, of the most brilliant reds, browns, buffs, and lustrous blacks. There is an erectile fleshy horn on each side of the head, and a loose wattle,

Tragopan, or Horned Pheasant (*Ceriornis satyra*).

capable of being inflated, lies like an apron on the throat. The best-known species are the Indian Crimson Tragopan (*C. satyra*) and the Black-headed Tragopan (*C. melanocephala*), inhabiting the forests on high ranges. In courtship the male 'shows off' his beauty in an elaborate way before his desired mate. The other species are *C. blythii* from Upper Assam, *C. caboti* from south-west China, and *C. temminckii* from central China. The tragopans are capable of acclimatisation, and possibly domestication, in Britain.

Train-bands. See MILITIA, Vol. VII. p. 192.

Training, in the wider sense equal to practical education in any profession, art, or handicraft, is frequently used in the specific sense of the method adopted by athletes for developing their physical strength, endurance, or dexterity, or to qualify them for victory in competitive trials of skill, races, matches, &c. Training in this sense consists mainly in bodily exercise, both general and specially adapted to the particular sport in view (as for running, rowing, boxing, &c.), and in sufficient and carefully regulated dieting. General exercising has been already considered at ATHLETICS and GYMNASTICS. The special training for boat-races, and the dieting suitable to all athletes are sufficiently dealt with at ROWING, Vol. IX. p. 10. Training may be overdone, to the serious and even permanent detriment of health. See Maclaren's *Training in Theory and Practice* (2d ed. 1874).

Training-colleges. See EDUCATION, Vol. IV. pp. 211–217.

Trajan. MARCUS ULPIUS TRAJANUS, Roman emperor, was born at Italica (near Seville) about 56. He was descended from a family which was probably of Roman origin, was early trained to arms, and gaining distinction in the Parthian and German campaigns was made prætor and consul (91), and was adopted (97) by Nerva as his colleague and successor. He became sole ruler in the following year. In 101 Rome for the first time beheld its emperor leading forth his legions in person on a career of conquest, when Trajan set out on his first campaign against the Dacians. The struggle was long and fierce; the emperor's opponents were valiant warriors, and headed by an able leader, their monarch, Decebalus; but the Romans at last gained a decisive superiority, and in a subsequent campaign (105) completely subdued their opponents, whose country thenceforth became the Roman province of Dacia, and was secured by partial colonisation. This conquest was celebrated on Trajan's return to Rome by a triumph, and by games on a most extensive scale. In 113 the emperor left Italy for his great expedition in the East, directed mainly against the Parthians. Landing in Syria he made Armenia and Mesopotamia into Roman provinces, and advanced to Ctesiphon on the Tigris, meeting however with actual defeat at Ctesiphon and Hatra. Meanwhile the Jews rose in Cyprus and Cyrene and made fearful massacres; and other enemies took advantage of the emperor's absence in the far east. Trajan took ship for Italy, already in failing health, and was overtaken by death at Selinus in Cilicia, August 117. Though most of Trajan's reign was spent in the field, the internal administration was carefully and excellently guided; the administration of justice was vigorous and impartial; that of finance was equally admirable; informers (*delatores*) were severely punished, and peculating governors of provinces rigorously prosecuted. The improvement and beautifying of Rome was carried on; the empire was traversed in all directions by new military routes, canals and bridges were constructed, new towns built, the Via Appia was restored, the Pontine Marshes partially drained, the magnificent 'Forum Trajani' erected, and the harbour of Centum Cellæ (Civita Vecchia) constructed. His mildness and moderation were proverbial; and though he persecuted the Christians, it was because he regarded the new religion as distinctly subversive of the state. His famous letter to Pliny (q.v.), then legate in Bithynia and Pontus, shows his character in this regard, and his sincere desire for the comfort and happiness of his subjects is reflected in the customary wish formally uttered on the occasion of an emperor's accession—that he might be 'happier than Augustus, better than Trajan' (*Augusto felicior, Trajano melior*). A popular mediæval legend even described him as saved by the prayers of Pope Gregory I. from the pains of hell. Trajan's Column is described at ROME, Vol. VIII. p. 782. Trajan's Wall is the name given to an old Roman earthwork in the Dobrudja, running from the Danube above Czernavoda to Kustendji on the Black Sea; it is an earthen wall, 8 to 15 feet high, and was defended against the Russians in 1854.

There are works on Trajan by Francke (2d ed. 1840), Dierauer (1868), and De la Berge (1877). See also Merivale, and H. Schiller's *Gesch. der Röm. Kaiserzeit* (Gotha, 1883).

Tralee, a town of County Kerry, on the Lee, about a mile from where it discharges into Tralee Bay, and 207 miles SW. of Dublin by rail. There is a ship-canal to the sea, but the trade of Tralee as a port has decayed since larger ships took to discharging at Fenit, 5 miles along the bay. Tralee returned a member to parliament till 1885. Pop. 9664.

Tram. See SILK, p. 455.

Trammel-net, one of the commonest of the *moored nets* described in the article FISHERIES.

Tramps. See VAGRANTS.

Tramways (Old Swed. *tram*, 'log, wooden sledge'). In the article on Railways (q.v.) the early application of rails for purposes of locomotion was referred to. From very early times

stone and wood had been used to lessen friction in the traction of heavy weights at quarries and collieries. The first use recorded of iron for this purpose was in 1738, when a 'plate-way' was laid at Whitehaven. Again in 1767 some cast-iron rails were laid in Coalbrookdale, and ten years later a cast-iron 'tramway' was nailed to wooden sleepers in a colliery belonging to the Duke of Norfolk near Sheffield, after the design of John Carr. Fearing a reduction of wages or lessened employment in the future, the labourers employed got up a riot and tore up the road, the inventor having to flee for his life. This 'tramway'—a name said falsely to be derived from one Benjamin Outram belonging to a Derbyshire family—as in other earlier specimens had a flange cast on its outer edge to keep the wheels on the road. It was not until 1789 that the great improvement was made of transferring the flange from the rail to the tire of the wheel, the track then assuming its present form.

In 1801 a tramway 28 miles in length, something of the modern type, was constructed for the Tredegar and Sirhowy ironworks in South Wales, and in the same year a public act was passed for the laying of a line near London from Wandsworth to Croydon. This tramway, which was designed for extension to Reigate, was intended to furnish a more ready means of transport (by horse and mule power) of coal and merchandise from the Thames to the districts south of London. But the undertaking failed to fulfil the hopes of its promoters, and on the discontinuance of its working the greater part of the route was occupied by the Brighton Railway Company.

The rapid development of the locomotive effectually diverted attention in England from the utilisation of rails for the purposes of ordinary street traffic; but as everything that tends to economise labour has for many years past found special favour in the United States, the Americans were not slow to discern the merits which the tramway system offered for the movements of the population. The Fourth Avenue (Harlem) Tramway was chartered in New York in the year 1831, about the time that the Manchester and Liverpool Railway was opened for traffic, but for about twenty years maintained a monopoly of the street railway traffic. A rapid extension of the system then followed, as towns in different parts of the Union increased in size. Philadelphia and Boston established street tramway lines in 1857, and at present every town on the North American Continent of any pretensions to the title—nearly 500 in number—boasts of one or more lines, in many cases worked by electricity. Of a total tramway mileage of over 17,000 miles in 1898, over 16,000 have electric cars; the others being propelled by steam, cable, gas-engines, or animals.

The reintroduction of tramways into the United Kingdom in 1858–59 was not a successful venture. An enterprising but reckless American (George Francis Train) obtained permission to lay several short lines in different parts of the country. The one first laid down at Birkenhead is still in existence, the more objectionable features of its construction having been modified, but the London lines were all laid down without special parliamentary authority, and their removal was, after a short trial, decreed by the different vestries concerned as a nuisance to existing traffic. The rails were of absurd shape, their projecting flanges making it almost impossible for ordinary vehicles to cross the line except at right angles, and even then at some risk to wheels and springs.

The removal of the toll-bars within the Metropolitan area, following on an agitation commenced in 1864, greatly facilitated the development of tramway enterprise, and in 1869–70 the leading London tramway companies were incorporated. Within about ten years from that date some 500 miles of street railway had been laid in different towns of the United Kingdom, and nearly 1000 miles are now in operation, representing an invested capital of about 13½ millions sterling, and carrying annually 500 to 600 million passengers.

With the development of the tramway system in all parts of the world the question of the relative merits of different forms of tractive power has naturally attracted wide-spread attention with the view of reducing the working cost. The advantages of electricity (see Vol. IV. p. 284) in the concentration of power and increased speed and efficiency, as compared with horseflesh, are generally recognised, and in the United States its use is rapidly superseding all other power. In Great Britain the objection to overhead wires to convey the electricity to the cars was more difficult to overcome, but in 1901 many towns, including London, Liverpool, Leeds, Glasgow, Dublin, Stockton, &c., had successful electric tramways working. The conduit or underground system of wires has not as yet been found quite suitable for general use. A system which is also much in favour is that of cable lines. The plan of using a rope or cable as a means of traction is of old date, and various patents have been taken out, something on the lines of the atmospheric railway, for the laying of an underground pipe, in which a rope should travel with a grip attachment on the cars capable of picking up or letting go the travelling cable. The first practical adoption of the idea was made in San Francisco, by a Mr Hallidie, who in 1873 opened the Clay Street cable line. The road in some parts has very steep gradients, impracticable for a horse-car line, and the success of the new method of traction for steep grades was at once established, and San Francisco has now nearly 100 miles of cable roads in operation. The system was adopted in Chicago ten years later, and was about the same time applied to the working of the Brooklyn Bridge traffic at New York. The application there was successful, the line conveying as many as 35,000 people in an hour between the hours of five and six at night. The superior advantages of electricity, however, are now acknowledged in the States.

American engineers were concerned in laying the first cable line in the United Kingdom, that on Highgate Hill, which was opened in 1884, and lines on this system have since been constructed in Edinburgh, where steep gradients exist, and in Birmingham and Bristol. The Brixton route of the London Tramways Company has been converted into a cable line, and in Australia and New Zealand several new cable systems have been laid down.

The figures in cents of the relative cost and working results obtained from the three systems of traction have been compiled by the American Street Railway Association from the statistics of 22 electric lines, 45 horse-car companies, and 10 cable roads as under:

	Electric.	Horse.	Cable.
Expenses per car mile	11·02	24·32	14·12
Interest charges "	3·03	4·62	6·97
Total expenses "	14·05	28·94	21·09

The superior speed to be attained on the electric and cable lines must of course be considered in calculating the capacity and probable returns received from the working of the various systems. The dividend earning powers are thus estimated:

	Electric.	Horse.	Cable.
Investment per mile of street	1·152	1·000	10·486
Miles run annually	1·757	1·000	7·138
Cost per car mile with interest	·485	1·000	·722
Proportionate traffic per street mile to earn 6 per cent.	·852	1·000	5·154

Taking the horse-car as the unit, the relative results are stated to be as above. It remains to be added that tramway enterprise in any form is a very profitable kind of investment. On the European Continent heavy taxes and subsidies are paid by most of the companies to the municipalities served, and in the United Kingdom, under powers expressly reserved by parliament, it is probable that many of the undertakings will be acquired and worked by the city authorities for the benefit of the ratepayers.

See works on the construction of tramways by Dowson (1875), D. K. Clark (1878), J. Bucknall Smith (1887), and A. W. Wright (Chicago, 1888); also the Parliamentary Returns on Tramways; Sutton and Bennett's *Tramway Acts* (1874; new ed. 1883), and G. I. Phillips, *Tramways Act, 1870; with Introduction, &c.* (1890).

Trance, a morbid sleep, differs from natural repose in duration; in profound insensibility to external impressions; in following excitement and the exaltation of certain instincts, chiefly the religious and amative, rather than fatigue or exhaustion; and in being the concomitant or symptom of diseases of the nervous system, particularly Hysteria (q.v.). It differs on the other hand from Coma (q.v.) in not being associated with serious organic disease, and in the absence of stertorous breathing, muttering, delirium, &c. See SLEEP, INSANITY, CATALEPSY, ECSTASY.

Tranent, a police-burgh of Haddingtonshire, 7½ miles east of Edinburgh. It has a fine school (1877), water-works (1883), and in the churchyard Colonel Gardiner's grave. Coal has been mined here since 1219. Pop. (1851) 2096; (1891) 2389. See P. M'Neil's *Tranent, &c.* (2d ed. 1884).

Trani, a seaport and archiepiscopal city of Southern Italy, 28 miles NW. of Bari by rail, with a 12th-century cathedral, trade in country produce, and a harbour nearly sanded up. Pop. 25,173.

Tranquebar (*Tarangambádi*), a seaport of Madras Presidency, 22 miles N. of Negapatam. A Danish settlement from 1624 to 1807, it passed finally to the English in 1845 for £20,000, and was a busy place till the construction of the South Indian Railway to Negapatam (1861) diverted away its trade. The first Protestant mission to India was established here in 1706. Pop. 6189.

Transcaspian Railway, starting from Uzna Ada on the Caspian, was opened as far as Merv in 1886, to Samarkand in 1888, and in 1892 was being extended to Tashkand. The Amu-Darya (Oxus) is crossed by a wooden bridge 6804 feet in length.

Transcaucasia, the tract of territory belonging to Russia, and extending between the Caucasus (q.v.) on the north and Turkey in Asia and Persia on the south. The provinces on both sides of the Caucasus, with the added Armenian districts, constitute Caucasus or Caucasia in the widest sense, and are under one central authority, with ten minor governments or provinces. But the government is sometimes divided into North Caucasus, Transcaucasia, and Armenia. Transcaucasia comprises seven governments (Kutais, &c.; for which see table at RUSSIA). And see Bryce's *Transcaucasia* (2d ed. 1878).

Transcendentalism. The words transcendental and transcendent (*transcendentalis, transcendens*) were employed by various Schoolmen, in particular Duns Scotus, to describe the conceptions that, by their universality, rise above or transcend the ten Aristotelian Categories (q.v.). Thus, according to Scotus, *Ens*, or Being, because it is predicable of substance and accident alike, of God as well as of the world, is raised above these by including or comprehending them; it has the same relation to the sum of the categories as the *summum genus* to the various genera within a single category. Further, the predicates assumed by Scotus to belong to *Ens*, or simple existence—the One, the True, the Good—are styled transcendent, because applicable to *Ens* before the *descent* is made to the ten classes of real existence.

Between the hitherto convertible terms, transcendental and transcendent, Kant himself drew a distinction of considerable importance for the understanding of his system. By the word 'transcendental' he designates the non-experiential, *a priori* elements of thought (see KANT)—especially the forms and categories (space and time, causality, &c.) which in his view, though they are not products of experience, are manifested only in experience, and contribute an essential element in all experiential knowledge. The word 'transcendent' Kant reserves for those among the transcendental or *a priori* elements that transcend and lie beyond all experience; they may seem to be given in experience, but they are not really given, and are in so far illegitimate as cognitions (though *belief* in them may be attained in other ways). Such are the 'ideas of the pure reason,' God, an immaterial soul, &c.

For post-Kantian systems which affirmed the identity of subject and object the distinction of transcendental and transcendent ceased to exist, and absolute knowledge was practicable; such systems are said to be or contain *transcendentalism*. 'Transcendental Philosophy' was Schelling's own name for an important part of his system (see SCHELLING). Oken and others carried much of this transcendentalism into their *a priori* construction of the nature-philosophy—in which in some cases scientific fact had to yield to speculative deduction. Transcendental has also often been used by 'common-sense' philosophers and the association school for the *a priori* generally. And in vulgar parlance the word applies to what is disapproved of as abstruse, speculative, obscure, fantastic, and as such absurd; it is specially familiar as a criticism of almost any form of idealism. See IDEA.

The epithet of Transcendental School has come, however, to be specially associated with a group of American authors and thinkers, who early in the 19th century led and cherished a wide-spread reaction against time-honoured Puritan prejudices, humdrum orthodoxy, old-fashioned metaphysics, and materialistic philistinism and utilitarianism. The movement was identified with idealism, vague pantheism, mysticism, and eclectic orientalism, and had at times a distinct flavour of the pedantic, the paradoxical, and the extravagant. Among the main exciting causes were the influence of Carlyle and the discovery of the new world of German literature. Brook Farm (q.v.) was one outcome of the school. The first meeting of the Transcendental Club took place in 1836 in the house of George Ripley (q.v.); other conspicuous members of the school were Margaret Fuller and Theodore Parker. Many well-known American authors, such as Hawthorne, have at some time shown affinities that way. But the thinker who most effectively summed up what was best in the movement, gave it the most permanent expression, and secured the widest hearing, was Ralph Waldo Emerson (q.v.). See O. B. Frothingham, *Transcendentalism in New England* (New York, 1876).

Transept. See CHURCH.

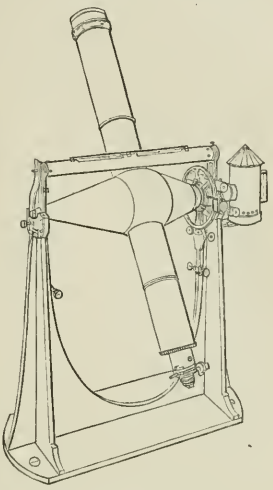
Transfiguration, FEAST OF THE, instituted in honour of the Transfiguration of Christ (Matt. xvii. 2), is one of the twelve great feasts which come next after Easter in dignity. In the Anglican Church it is only a Black-letter feast. It is commonly said to have been instituted in the West by Pope Calixtus III. (1455–58), but is mentioned in

the 9th century. Both Greeks and Westerns keep it on the 6th August.

Transformer. See ELECTRIC LIGHT.

Transfusion of Blood consists in the transference of blood from the veins (or arteries) of a healthy person to one whose blood is so impoverished as to endanger life. The earliest case on record is, so far as we know, that of Pope Innocent VIII., who is said to have been unsuccessfully operated on in April 1492. In 1667 the operation was performed both in France and England, apparently with success; but it again fell into oblivion till 1824, when Dr Blundell, in his *Researches*, proved the feasibility of the process. Since that time it has been regarded as a legitimate operation, and has frequently been successful in apparently hopeless cases; but the difficulties attending it are sufficiently indicated by the number of different procedures and kinds of apparatus devised for its performance. It has been used most frequently and successfully in cases of profuse hæmorrhage after child-birth; but also in many other conditions—e.g. phthisis, puerperal fever, pernicious anæmia, poisoning by agents which destroy the blood-corpuscles or impair their activity. The blood of the lower animals has been shown to be unsuitable for this purpose, and sometimes dangerous. The first requisite, therefore, is to find a healthy person able to spare blood enough for the purpose. Saline solutions, pure water, and milk have been used; the last is strongly recommended by Professor Thomas of New York. But though their mechanical effect is sometimes sufficient to tide over the crisis, they do not supply the deficiency in blood-corpuscles. The chief difficulty in the performance of the operation is the prevention of coagulation of the blood before it reaches the blood-vessels of the patient. This has been surmounted in three ways: (1) by direct transfusion—i.e. rapid transference through a short tube; (2) by the addition of chemical substances which prevent coagulation; (3) by removing the fibrin before injection (see BLOOD). See C. E. Jennings, *Transfusion of Blood and Saline Fluids* (3d ed. 1888).

Transit-instrument, one of the most important of astronomical instruments, consists of a telescope fixed to a horizontal axis, so as to revolve in the plane of the meridian. It is employed, as its name denotes, in the observation of the meridian transits of the heavenly bodies—i.e. the apparent passage of the heavenly bodies across the observer's meridian, an appearance due to the revolution of the earth (for the transits of Venus, see SUN, Vol. IX. p. 803). The axis, which is the most important part of the instrument, and thus demands the utmost care in its construction, consists of a hollow sphere or cube, to opposite sides of which are tightly fastened the bases of two cones in whose apices the pivots are screwed; the sphere or cube is pierced for the admission of the telescope, which is firmly soldered at right angles to the axis. One of the pivots is hollowed so that a stream of light can be directed from a lantern, through an aperture in the side, and half-way along the interior of the axis, into the telescope tube, where, being received by an annular mirror set at 45° to the axis and telescope tube, it is directed to the eyepiece, and brilliantly illumines the field of view, while the annular form of the mirror prevents any interference with the passage of rays from the object under observation to the eye. The pivots must be very carefully turned to a perfectly cylindrical form, and fitted into the instrument, so that their axes are accurately in line. One extremity of the axis carries one and sometimes two small graduated circles, each supplied with index, clamping screws, and vernier; these circles are capable of indicating angular measures to within 1′ or 2′. The pivots rest on massive blocks of stone or other stable material which is little affected by change of temperature, stability being the great mechanical essential of the instrument. This condition satisfied, there are three adjustments necessary before a transit can be observed: the axis must be horizontal; the line of collimation must be at right angles to the axis of motion; and the latter must be placed so as to point accurately east and west. On the perfection of the first two of these adjustments depends whether the telescope sweeps over a great circle of the sphere, and the third is necessary to ensure that this great circle shall be the meridian of the place of observation. These adjustments can never be made quite perfect, and the usual mode is to investigate the amount of error in each, and allow for it in the apparent result. To note accurately the instant of time by the astronomical clock at which the object (e.g. a star) is seen to pass the centre of the field of view is the essential part of a transit observation. The most effective method is to register the beats of the clock by an apparatus which at the end of each oscillation of the pendulum marks a dot upon a uniformly moving slip of paper. This is effected by the agency of electricity, and is one of its most valuable contributions to astronomical science. At a certain point in each oscillation of the pendulum it becomes part of a complete galvanic circuit, the contact being immediately broken by its progression in its oscillation; and it is at these points that the galvanic agency causes the dot to be made. The instant of a transit's occurrence is similarly noted by the observer, who, by a tap on a break-circuit key, fastened to the side of the transit-instrument, causes the graver to make an extra dot; and the distance of this dot from the previous seconds one, compared with the distance between two seconds dots, gives the time accurately almost to $\frac{1}{100}$ of a second. Various ingenious modes of registering have been proposed, all founded on the above principles. It is from the times of transit of the several heavenly bodies thus accurately observed that their right ascensions are determined.



Transit-instrument.

The transit-instrument was invented by Römer about 1690. One was erected in Greenwich Observatory by Halley in 1721; but it was little used till 1742. The transit-instrument there now is by Troughton, and was erected in 1816.

The transit-circle differs mainly from the older transit-instrument in the addition, on the axis of rotation, of two large graduated circles which are read off by microscopes fixed on an independent coaxial wheel called an alidade, any variation in the position of which may be detected by a large spirit-level attached to it. This instrument is as well suited for giving the declinations as for giving transits or right ascensions.

Transition is a term applied to the architectural features of buildings erected at periods intermediate between the fully-developed 'styles'

technically so called. Thus in Britain there is a transition between the Norman and First Pointed or Early English, another between the First Pointed and the Decorated or Middle Pointed, and a third between the Middle Pointed or Decorated and the Perpendicular. See ARCHITECTURE.

Transkei Territory is a part of the Cape Colony, lying between the Great Kei River (the boundary of British Kaffraria) and the borders of Natal. Covering most of the former Kaffraria proper, it is now divided into Griqualand East, Tembuland, and Transkei in the stricter sense —the latter comprising Fingoland, the Idutwya Reserve, and Galekaland. The last independent portion, Pondoland, was annexed in 1884, but differs from the rest in having a resident commissioner appointed by the Cape government.

Translation, the art of rendering what is written in one language into its corresponding sense in the words of another. Obviously it should first be faithful—a reproduction of the sense and ideas rather than a paraphrase; contrasted with this prime quality all such ends as preserving the colour, the music, the idiomatic vigour, the distinctive manner of the original are counsels of perfection. To translate perfectly is to interpret to the last detail; and to interpret it is necessary to understand. The feeling is more important than the exact word, and the admonition of Dryden may be commended to the adult translator, if not the schoolboy—not 'to lacquey by the side of his author, but to mount up behind him.' It is difficult enough to express one's own meaning to one's wish; doubly difficult is it so to realise another's as to express it as he would have done had ours been his mother-tongue. A literal translation is better than a loose one, but obviously in the case of idioms and metaphors of special meaning the literal rendering cannot be the right one, for in such mechanical transposition the spirit and perfume will be found to have evaporated in the transfusion. 'Translation from one language into other,' said Don Quixote, 'is like looking at Flemish tapestries on the wrong side; for though the figures are visible, they are full of threads that make them indistinct, and they do not show with the smoothness and brightness of the right side. Yet,' he continues, 'a man may employ himself in ways worse and less profitable to himself,' and we need not cut ourselves off from some of the richest springs of human thought and experience because the drinking vessels available are seldom of exquisite workmanship. A prose translation of a poem like the *Iliad* or the *Æneid* can be of course only an approximation to the ideal translation—a shadow of the reality, like the music of the sea, heard but in a shell, the colour being lost, the light and shade altered as in a photograph. Yet such translations as those of the *Odyssey* by Butcher and Lang, the *Iliad* by Leaf, Lang, and Myers, Theocritus by Lang, Sophocles by Jebb, Pindar by Myers, Virgil by Conington or Mackail, the *Inferno* by Dr Carlyle or C. E. Norton, the *Purgatorio* and *Paradiso* by A. J. Butler, are masterpieces of triumph over the difficulties of their kind. Of all books the Bible, or more strictly the New Testament, loses least in translation, the language being itself a product of a degenerate stage of Greek, the ideas to be conveyed relatively direct and simple, the matter being much more heeded than the manner. Fortunately for our literature the English translation was made at a time when the language had reached its period of fullest simplicity and vigour.

To lay down canons of translation will not help much in the matter, for the best translators are those who possess an individuality as well as their originals, such as Edward FitzGerald, whose versions from Calderon and Omar Khayyam, wide of their text as they frequently are, yet succeed to perfection in reviving in a sympathetic English reader the effects produced by the original. Hookham Frere's free versions of Aristophanes are perhaps the best things of their kind that have ever been done. The translation ought to be such that the reader should, if possible, forget that it is a translation at all, and be lulled into the illusion that he is reading an original work. Or again, the translator should retain every peculiarity of the original, so far as he is able, with the greater care the more foreign it may happen to be. Such are some of the more or less perfunctory attempts to lay down definitions of translation, and we need only say in short that this, instead of being the easiest, is one of the most difficult of tasks, only to be essayed by men who are at once masters of both languages and of the subject-matter of the book to be translated. What men thus adequately equipped can make of an ancient author we see when we turn to Jowett's Plato, Munro's Lucretius, Conington's Persius, Long's Marcus Aurelius and Epictetus, Reid's *Academica* and *De Finibus* of Cicero, Church and Brodribb's Tacitus, also the *History* by Albert W. Quill, Rann Kennedy's Demosthenes, Jebb's *Characters* of Theophrastus, Shuckburgh's Polybius, Lewis' Juvenal, Macaulay's Herodotus, Welldon's Aristotle (*Rhetoric* and *Politics*), and the *Ethics* by F. H. Peters, Verrall's Æschylus (*Agamemnon* and *Septem contra Thebas*), Dakyns' Xenophon; or, of English translations from modern languages, the *Thousand and One Nights* of Edward Lane, of John Payne, and of Sir R. Burton; the *Don Quixote* of John Ormsby, and of H. E. Watts; Pascal's *Pensées* by Kegan Paul; Van Laun's Molière; Carlyle's *Wilhelm Meister;* and from the old Icelandic, the 'Saga Library' of Morris and Magnússon. Urquhart's Rabelais, Florio's Montaigne (as well as that by Cotton), North's Amyot's Plutarch, Shelton's *Don Quixote*, Painter's *Palace of Pleasure*, Philemon Holland's Livy, Hobbes's Thucydides; as also such metrical translations as Gavin Douglas' *Æneid*, Harrington's Ariosto, Fairfax's Tasso, belong to a special group in English literature, valued more for their excellent English than for their accuracy. Among modern poetical translations especially notable are Coleridge's *Wallenstein*, Gifford's Juvenal, Cary's Dante, Calverley's Theocritus, Philip Worsley's *Odyssey* and that by William Morris, Plumptre's Æschylus, E. D. A. Morshead's trilogy of Æschylus (the *Agamemnon* better than Milman or Robert Browning), Lewis Campbell's Sophocles, W. H. Pollock's *Nuits* of Alfred de Musset, Lang's *Ballads and Lyrics of Old France*, Rossetti's group of translations from Italian poets entitled 'Dante and his Circle.' The difficulty of translating is well expressed in the punning Italian proverbial saying, that the translator is a betrayer (*Traduttore traditore*). Elphinstone's Martial has the merit of being among the worst, and Dryden's versions of part of Juvenal among the best, of their kind. Horace, the despair of translators, has yet been well treated by Conington and Sir T. Martin; Homer forms a library of itself, famous poetical versions being those by Chapman, Pope, Cowper, and Lord Derby; Chapman preserves the strength of the original, but his fanciful quaintness is a grievous impediment. Pope's *Iliad* is a noble poem, but, as Bentley said with fatal truth, 'you must not call it Homer.' It lacks its naturalness, its flowing simplicity, the Homeric ideas having gained a completely un-Homeric colour in the crucible of a characteristically 18th-century intellect.

There are some excellent remarks on translation by Jowett, in the preface to the third edition (1892) of his Plato.

Transmigration, or METEMPSYCHOSIS, the transition of the soul after death into another substance or body from what it occupied before—a belief deeply rooted alike in primitive belief and ancient philosophical speculation, and at the present moment widely spread within the range of Brahmanism and Buddhism. It is of course to be carefully distinguished from the metamorphosis of living men, which we find in lycanthropy and witchcraft; it is much wider in its range than the Christian doctrine of the resurrection of the body; and it obviously presupposes a belief in the immortality of the soul, although the ethical conceptions of reward and punishment and of the causal connection between this and a future life are developments of the doctrine unknown, or but rudimentary, at the lower levels of civilisation. The simplest form of this belief is found amongst several tribes of Africa and America who think the poor shivering soul at death must look out for a new host to inhabit, and if need be will enter the body of an animal. This re-incarnation is most often considered as taking place through the soul of a dead man animating the body of an infant of his own kindred or descent, thus accounting naturally for the likeness between parents and children and for the stranger phenomena of atavism. And hence even the persistent transmission of old family names is not without its significance. The Yoruba negroes greet a new-born child with the words 'Thou art come,' and then decide which ancestral soul has returned. Many peoples in Africa consider white men their own *manes* returned from the grave, finding proof both in their pale colour and superior wisdom.

Still further the primitive notions of the intimate brotherhood between men and beasts make it easy to account for the transmission of human souls into the bodies of the lower animals. Familiar examples of this are the Zulu *amatongo*, ancestral snakes which may even be identified by some peculiar mark similar to what the man bore in life, and the birds which the Iroquois set free on the evening of a burial to carry away the soul. Both Brahmins and Buddhists admit human descent not into beasts alone, but plants and trees, and the Buddha himself, before his last birth as Sakyamuni, underwent as many as 550 births through such stages as a hermit, a king, a slave, an ape, elephant, snipe, fish, frog, and the genius of a tree. When he attained the perfect knowledge of the Buddha he was able to recall all these existences, and these accounts form the *Jatakas*. The doctrine of transmigration (Samsâra) does not seem to have belonged to the early Aryan faith, but it lies at the heart of the accepted Indian philosophy, affording a satisfactory explanation of the phenomena of phenomenal existence. The present is ever determined by the past in an unbroken line of causation, and every sentient being is a prey to ever-renewed suffering and sin, destined after every new existence to be born in some new form. The real aim of life is to discover by what means to obtain release from the burden of material existence and find union in absorption with the Supreme Self.

It seems certain that the ancient Egyptians believed in the transmigration of souls; among the Greeks it was a doctrine especially associated with Pythagoras, and apparently with the Orphic and other mysteries. Pythagoras, we are told, himself recognised in the temple of Hera the shield he had borne as Euphorbus at the siege of Troy. The bodily life of the soul is itself an imprisonment for sins committed in a former state of existence—the reward of the best men is to enter the *kosmos;* of the worst, to sink to Tartarus. The general lot is to live anew in human or bestial forms according to the degree of guilt to be atoned for. This same doctrine of retribution and purificatory wandering meets us again in Plato's speculations on the future life. Among the Jews the Kabbalists accepted the doctrine (*Gilgul Neshamoth*), and it formed an essential part of the Manichæan philosophy. Into Christianity it has never made much way, for although the doctrine of pre-existence touched it at one point, yet the souls of all mankind created by God before the world remained still and silent in the realm of potentiality until united with human bodies at generation. A shadow of transmigration appears in the vagaries of Swedenborg, and it has continued to survive in the speculations of occasional philosophers. Even a thinker so strong as Lessing adopted it as a theory to account for the infinite conceptions of which the finite soul is capable, these being only acquired gradually in an infinite succession of time. See ANIMISM, ANIMAL-WORSHIP, BUDDHISM, EGYPT (RELIGION), IMMORTALITY, PRE-EXISTENCE; and cf. THEOSOPHY.

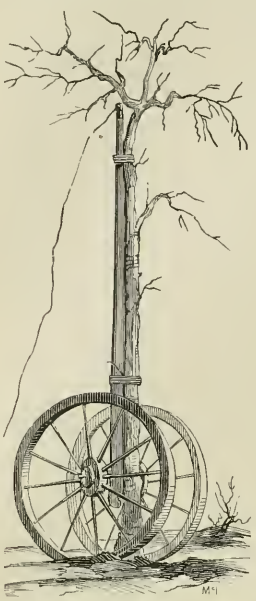
Transmission of Power means the doing of useful work at a distance from the engine or whatever other source supplies the energy. An ordinary tow-rope evidently fulfils such a function; and in a wide sense all forms of connecting rods, Belting (q.v.), and similar gearing (see WIRE-ROPES) do the same. The revolving shaft of a screw-steamer transmits rotatory motion through a considerable distance; but for long distance transmission ordinary mechanical devices, if they do not altogether fail, lose greatly in efficiency. In a series of shafts geared one to another by beltings there must be considerable loss through slipping. In the Pneumatic Despatch (q.v.) and in Boring (q.v.) compressed air has been successfully applied as a transmitter of power. Cable cars (see TRAMWAY) also form a good illustration. It is in electricity, however, that we find the most promising agent for indefinite transmission of power. Thus a dynamo-electric machine may be worked by a waterfall; its voltage or potential may be transmitted along wires to distant stations, and there transformed into currents capable of driving an electric motor and keeping a whole factory in operation. At the Frankfort Exhibition (1891) such a power was transmitted 109 miles. See DYNAMO-ELECTRIC MACHINERY, ELECTRIC LIGHT, NIAGARA.

Transpadane Republic. See CISALPINE.

Transplanting, the act of removing bodily a plant or tree from the place in which it grows, and establishing it in the same or another place. The operation is in continual practice in gardens and nurseries throughout the year, and it is of immense practical utility. But for the facility with which the great majority of cultivated plants may be transplanted, gardens would be comparatively profitless and uninteresting, and pleasure-grounds and the landscape be adorned only with indigenous forms of trees, shrubs, and flowers. In the large trade nurseries transplanting is one of the chief occupations of the workers. Seedling forest trees are reared annually in hundreds of thousands, and either are transplanted in the nursery to adapt them for special purposes, or are transferred from the seed-bed at the age of one or two years direct to moors and hillsides to form woodlands. Ornamental shrubs from all temperate countries are in the same way prepared for distribution. Fruit trees are especially benefited by the process. By frequent transplantings fruitfulness is accelerated in young fruit trees, and the operation is systematically resorted to in order to maintain fertility in those that are more aged.

The operation is most practicable in the youthful stage of all plants. In those that are aged and have been long established in one place it is attended with danger, chiefly because in the case of large trees and shrubs it is impracticable to

preserve uninjured a sufficiency of the fibrous roots to draw nourishment from the soil. Yet very large trees have been successfully transplanted. At Chatsworth, Dropmore, and many other places trees exceeding 50 tons weight have been transplanted from one situation to another several miles distant. Such herculean operations in transplanting, while quite practicable, are attended with an amount of expense and hazard which precludes their being generally engaged in. Yet at the places named, and others equally notable, sylvan effects have been created in bleak, treeless situations in two or three years by this means, which would have taken half a century to produce in the ordinary course. In moving trees of a size exceeding that which two or three men may easily handle, transplanting machines are required. These are of various kinds, and each has special merits not possessed by others. The best machines for the removal of very large trees from one place to another are Barron's and M'Glashan's. These two inventions have some features in common; they are ponderous four-wheeled carriages in which the tree is swung in chains or on a platform upright as it grew, and may be carried any distance where bridges overhead do not occur in the way. M'Nab's apparatus (see figure) is the best for lifting trees and shrubs of considerable size, but is incapable of the ponderous work of either of the other machines, and it has the further disadvantage that the tree must be carried in a horizontal position. The transplanting of large trees successfully involves the possession of considerable experience of the work by the person superintending it. He should know the proper time or season for the transplanting of each kind of tree with which he has to deal. Various kinds of trees are not all amenable to the same methods. Greater care is required in every stage of the work with some than with others. The prime object to keep in view in every case is the preservation of the fibrous roots; every one of these destroyed lessens the chances of success. When it is determined to transplant trees which have been growing undisturbed for some years, it is necessary to prepare them one or two years prior to lifting them. A trench is opened in a circle 2, 3, or more feet—according to the age and size of the tree—from the bole all round, and all the roots are cut off beyond the circle. The trench is carried deep enough to reach all the roots, and is then filled up either with the earth excavated or, in cases requiring special care, with soil of a kind more favourable to the formation of fibrous roots. The mutilated roots send out new feeders into the new soil, and if the work has been properly done they will be numerous enough one or two years hence, according to the peculiarities of the subject, to bind the new soil in a compact mass, and thus facilitate the transportation of a considerable ball of earth along with the tree.



M'Nab's Transplanter.

Limes, poplars, willows, and such-like quick-growing and free-rooting trees are more easily transplanted when of considerable age than oak, beech, sycamore, and the like. Evergreen trees and shrubs transplant most successfully in spring, when they are beginning to grow. Deciduous subjects on the other hand succeed best when transplanted immediately after the fall of the leaf. Surrounding the roots with light compost and watering, and mulshing the area over which the roots extend to lessen evaporation, are ordinary but essential means to success, especially in the case of large and difficult subjects. Securing the tree at once against disturbance by wind after it is planted is of vital importance.—For the transplanting of skin, see SKIN, RHINOPLASTIC OPERATIONS; and of teeth, see DENTISTRY.

Transport. See COMMISSARIAT, NAVY.

Transportation, technically as distinguished from Banishment (q.v.), the removal of offenders beyond seas, but loosely used for the removal of convicts to foreign or distant regions by sea or land. The history of English transportation is fully treated at PRISONS. For French and Russian transportation, see GUIANA, NEW CALEDONIA, SIBERIA.

Transposing, in Music, is changing a piece of music in performance from the key in which it is written to another key. To play at sight an accompaniment for such an instrument as the pianoforte or organ, transposed from one key to another, requires considerable artistic skill. To the singer transposal presents no difficulties.

Transubstantiation. The meaning of the theological term transubstantiation is made apparent in the following canon of the Council of Trent: 'If any one shall say that, in the most holy sacrament of the Eucharist, there remains the substance of bread and wine together with the body and blood of our Lord Jesus Christ; and shall deny that wonderful and singular conversion of the whole substance of the bread into the body, and of the whole substance of the wine into the blood, the species of bread and wine alone remaining—*which conversion the Catholic Church most fittingly calls Transubstantiation*—let him be anathema' (*Conc. Trid. Sess.* xiii. Can. 2). The canon just quoted was intended as a condemnation of the theories of impanation and consubstantiation. According to the theory of impanation, which was advocated chiefly by Osiander, in the sacrament of the Eucharist the bread and wine are hypostatically or personally assumed by the Divine Word. According to the theory of consubstantiation, which was favoured by the large majority of the Lutherans, the substance of the bread and wine remain together with the body and blood of Jesus Christ, but without being hypostatically assumed.

The doctrine of transubstantiation is then an article of Roman Catholic faith. Furthermore, the Council of Trent in the same Session xiii. declares that this doctrine 'has always been the conviction in the church of God.' Protestant divines call in question the truth of this declaration, and assert that the doctrine was unknown before the middle ages. Roman Catholic theologians on the other hand, while admitting that the *term* transubstantiation is comparatively new, profess their ability to prove by a *catena* of witnesses, commencing with the earliest ages of the church, that the *doctrine* conveyed by the term has been believed from the first. That the *term* is comparatively new is unquestionable. Cardinal Franzelin, indeed (*De Eucharistia*, page 177), gives instances of its use by Catholic writers in the 11th and 12th centuries. Nevertheless it was not formally adopted into the doctrinal phraseology of the church before 1215,

when it was employed in a profession of faith drawn up by the fourth Lateran Council. After this period we find the term again employed in a 'confession of faith' which was presented for subscription to Michael Palæologus, the Greek emperor, by Pope Clement IV. (1267), and was professed by the emperor in the second Ecumenical Council of Lyons held in 1274 under Pope Gregory X.

That the *doctrine* conveyed by the term transubstantiation is at least much older than the term all historians must admit. Berengarius of Tours, who had attacked the prevalent teaching on the Eucharist, was required by a council held in Rome under Pope Gregory VII. (1079) to make the following profession of faith: 'I, Berengarius, believe in my heart, and profess with my lips, that the bread and wine which are placed on the altar are *substantially changed into* the true and proper and life-giving flesh of our Lord Jesus.' And in the largely attended council held at Piacenza (1095), seven years after the death of Berengarius, it was once more declared that 'the bread and wine, when they are consecrated upon the altar, are *truly and essentially changed into* the body and blood of our Lord.' In a treatise *On the Sacrament of the Body and Blood of Our Lord Jesus Christ*, written by Paschasius Radbertus (831), the author very plainly stated the doctrine of transubstantiation. Some of the views expressed in this treatise were traversed by Rabanus Maurus, Ratramnus, and other contemporary writers; but the author's teaching on transubstantiation was challenged by no one.

It is admitted, with more or less of unanimity, that from the days of Paschasius Radbertus down to the period of the Reformation the doctrine of transubstantiation was in general acceptance. But when the inquiry turns upon the belief of the early fathers this unanimity disappears. Catholic theologians assert that the expressions employed by the Greek and Latin fathers, when treating of the effect of the Eucharistic consecration on the substance of the bread and the wine, are irreconcilable with any theory but transubstantiation. Leibnitz is disposed to grant the truth of this contention. 'The records of pious antiquity,' he writes, 'plainly enough demonstrate that the bread is changed into the body, and the wine into the blood of Christ; the ancients, too, universally acknowledged therein a change of substance, which the Latins have aptly rendered transubstantiation' (*System of Theology*). But in making this concession Leibnitz parts company with the great majority of Protestant divines. The latter contend that the change indicated by the language of the fathers is not a change in the substance of the elements, but a change in their use, efficacy, and dignity.

Transubstantiation is a doctrine not only of the Roman Catholic, but also of the Greek Church. In 1643, as a protest against the Calvinist 'Confession of Faith,' which had been drawn up by Cyril Lucaris, and circulated amongst the Christians of the East, and with the view of preventing any further attempts to unite the Reformed and Greek churches, a 'Profession of Orthodox Faith' was formulated by Peter Mogilas, archbishop of Kieff and primate of all Russia, and was subscribed by Parthenius, patriarch of Constantinople, Joannicius, patriarch of Alexandria, Macarius, patriarch of Antioch, Paisius, patriarch of Jerusalem, and the other metropolitans and bishops of the Greek and Russian churches. This profession, which is divided into 'Questions,' treats from question 98 to question 119 of the seven sacraments, explaining the use, nature, sanctity, and efficacy of each. Under question 107 the doctrine of transubstantiation is distinctly enunciated as follows: 'When these words (of consecration) are pronounced, immediately transubstantiation (ἡ μετουσίωσις) takes place; the bread is transubstantiated into the true body of Christ, and the wine into the true blood, the species alone remaining.' At the Synod of Jerusalem, held (1672) under the presidency of the patriarch Dositheus, this profession was solemnly confirmed as the expression of the faith of the entire Eastern Church.

Transubstantiation differs from all natural changes in this, that natural changes, even though they may be substantial changes, such as, e.g., the conversion of food by the processes of assimilation into the substance of the person nourished, or the conversion of wood into ash by the action of fire, are, at most, transformations. When, e.g., wood is converted into ash, the *form* or *active* principle which made the original substance to be wood gives place to a *form* that makes the substance, which is the term of the change, to be ash. But the *matter* or *passive* principle, which before the change was the subject or recipient of the substantial form of wood, remains after the change as the subject or recipient of the substantial form of ash. And thus in all natural changes, even though they be substantial, there is not an entire but only a partial change of substance. The active principle of the original substance is changed, but the *passive* principle remains. In transubstantiation, however, both the *matter* and the *form* of the bread and wine are changed, for, according to the Tridentine definition, there is a 'conversion of the whole substance of the bread into the body (of Christ) and of the whole substance of the wine into the blood.' Another respect in which transubstantiation differs from all natural changes is indicated by those other words of the Tridentine definition, 'the *species* of bread and wine remaining.' By *species* is here meant *accidents*. As *accidents* have no existence of their own, but exist with the existence of the substance in which they inhere, it follows that when that substance is destroyed its accidents must in the ordinary course of things cease to be. Thus, e.g., the external manifestations and the active and passive qualities of wood do not exist after wood has been converted into ash. But in transubstantiation the external manifestations, such as shape, colour, flavour, odour, &c., the passive powers of corruption, &c., the active powers of nutrition, &c., and the other forces and characteristics of bread and wine, continue to exist and to operate after the destruction of the substances on which they naturally depend. To hold, as Magnan and other Cartesians have done, that these accidents remain as mere phenomena and subjective impressions, void of objective reality, is to hold what is in opposition not only to experience, but also to the common teaching of the Catholic Church, as expressed, e.g., in the 'Catechism of the Council of Trent,' part ii., chap. 4, q. 43. But though the accidents persist after the subject in which they naturally inhere is withdrawn, they do not acquire the mode of being which is proper to substance, for they exist not *per se*, but by the 'extraordinary concursus' of God, and, while not actually existing in substance, they still retain an essential relation to substance as their subject. S. Thomas Aquinas (*Sum. Theol.*: tertia pars, q. 77, art. 2), holding with Aristotle that extension is the 'first disposition' of matter, and that all other accidents in consequence are referable to material substance 'through the medium of extension,' is of opinion that the extension of the bread and wine receives from God the power to act as the 'quasi subject' and support of those other qualities of bread and wine which manifestly exist and operate after transubstantiation has been effected.

Transvaal (till 1900 THE SOUTH AFRICAN REPUBLIC), a British crown colony in the highlands

of South-east Africa, bounded on the N. by Rhodesia, on the E. by Portuguese East Africa and Zululand, on the SE. by Natal, on the S. by the Orange River Colony, and on the W. by Bechuanaland. The length of the country from the Vaal River, its southern boundary, to the Limpopo River, which marks its northern limit, is over 400 miles, while a line between the extreme southern and eastern points running from 25° to 32° E. long. reaches 700 miles. The area is 120,000 square miles, about the size of the British Islands.

Previous to 1830 the land was a *terra incognita* so far as European knowledge or influence went, and was inhabited by several clans of the Bantu race, speaking dialects of the Bantu tongue. These clans were ruled by a branch of the Zulu race under the paramount chief Umziligase. The country was noted for its abundance of game; on the great undulating plains of the High Veldt or plateau (from 4000 to 7000 feet above the level of the sea) many varieties of the antelope family roamed in tens of thousands. In the valleys and well-timbered savannahs of the low country large game, consisting of the giraffe, elephant, buffalo, lion, leopard, &c., abounded, causing many parts to be dangerous for human habitation. The large rivers were full of alligators, hippopotami, and fowl; indeed, early hunters such as Harris and Gordon Cumming found here a sportsman's paradise. The fifth decade of the 19th century saw the first concerted intrusion of Europeans on this wild scene. A few Cape Colony farmers, offended by some regulations promulgated by certain crown officials, sacrificed their land and belongings, harnessed their cattle to their long lumbering wagons, and, taking with them their families and the most rudimentary necessaries of life (as well as a good supply of lead and powder and a tried musket), struck for the north, preferring the chances of death by wild animals or wild men to the irritating exactions of petty officialdom.

The pastoral wealth of the country was such that during the subsequent years on to 1870 the stream of Boer *voortrekkers* (Anglice, 'pioneers') fitfully continued to enter, fight for, and possess the land. They had a number of sanguinary battles with Umziligase and his paramount clan. After great slaughter of both sexes and all ages on both sides, the black chief and his people were forced to migrate over the Limpopo, where they peopled the territory of Matabeleland now occupied by their descendants. The other native clans lived on with the Boers, and were gradually subdued or driven out. Native wars were of frequent occurrence, and little progress was made in the development of the country. The Boers then, just as they are to-day, were essentially pioneers. They had none of the trader's instinct, and they did not till the soil to any great extent. Their land rights being scattered far and wide over a country without communications and with no markets to speak of, consumption of soil products was limited to the wants of the individual producer. The little commerce was in the hands of British firms, and nine-tenths of the trade of the country, export and import, remains in British hands.

In 1877, owing to an exhausted public treasury and accumulated debts brought about by chronic native wars, the republic was on the eve of dissolution, and the country about to relapse into barbarism. To avert this catastrophe the British government assumed the care of it, subjugated by imperial forces and Swazi levies certain rebellious natives, and put the finances of the state in order. The promises to the Boers, however, on the subject of self-governing institutions made for the home government at the time the country was annexed were not carried out. Arbitrary officials and military martinets were appointed to rule on behalf of the crown. By reason of their lack of tact, as well as of irritating regulations and the non-fulfilment of political engagements, friction was created between the governing and the governed—the English and the Boers. The spark which caused the explosion that had its final and humiliating episode in Majuba (q.v.) was an ill-timed enforcement of a petty tax. The English officials called out the Queen's troops in ignorance of the fact that the whole state felt sympathetic with a now common cause. Then followed the Transvaal war, the death of General Colley, and the signing of terms of peace, resulting in the conventions of 1880 and 1884 between England and the Transvaal. The first gave the Boers republican rights, but retained British control over boundaries, native affairs, and foreign relations. The 1884 convention restricted British suzerainty to the control of foreign relations. The rapid development of the gold industry greatly increased the financial prosperity, but introduced elements of difficulty into public life. For, as the Boers reserved all political power to themselves, the British and other 'Uitlanders,' to whom the wealth of the country is mainly due, resented not merely their exclusion from political privileges, but the oppressive action of the government in regard to mining regulations, monopolies for the sale of dynamite at exorbitant prices, the unfair incidence of the taxation (the new-comers bearing the great bulk of the burden), and other grievances. The discontent of the Uitlanders, a large majority of the total population, centred principally at Johannesburg, took overt shape in 1895, and led to the disastrous invasion by Dr Jameson in December (see JAMESON). Many acts of petty tyranny further accentuated the discontent, and the shooting of a British subject named Edgar by a Boer policeman finally roused the Uitlanders. A petition signed by 21,000 British subjects was sent to Her Majesty through the High Commissioner in March 1899, pointing out that their grievances, instead of being remedied as promised, had rather been aggravated since the Jameson Raid; the enforced submission of the High Court to the Raad, and the fact that trial by jury meant trial by Boers, made justice impossible. Negotiations ensued between the Colonial Office and the Boer government, which repudiated British suzerainty and claimed the position of a sovereign international state. A conference between Sir Alfred Milner, the High Commissioner, and President Kruger was held at Bloemfontein (31st May) to consider certain franchise and other proposals, but without effect, the suzerainty being still repudiated and the arbitration suggested by the Transvaal government being rejected by the Home authorities; and relations rapidly got more strained. In September the Orange Free State announced its determination at all hazards to support the Transvaal, which sent large bodies of burghers to the frontier and seized £800,000 of gold from the mines. The British government in reply called out 25,000 of the reserve forces. On October 9th the Transvaal presented a note demanding that all troops on the frontiers be instantly withdrawn, that all reinforcements sent to South Africa since June 1st be removed, that none of the troops then on the high seas be landed in South Africa, and requiring an answer within two days. As it was out of the question for Britain to concede these demands, the Boer ultimatum was virtually a declaration of war, and on the 11th the Boer forces invaded Natal and the burghers of both republics were called out for service. From the state of their preparations, the number and quality of their guns and rifles, and the enormous quantity of ammunition and other stores, it was seen that the republics had been secretly

preparing for war for years. On account of the distance from Britain and the difficulties of transport the Boers had considerable successes at first, especially in Natal, where they invested Ladysmith and 9000 men; but as the British forces increased till nearly 250,000 men were in the field under Lord Roberts, the tide of war turned against the Boers. Kimberley (16th February), Ladysmith (28th February), and Mafeking (17th May) were relieved; Cronje was captured (27th February) with 4000 men; Bloemfontein (13th March), Johannesburg (31st May), and Pretoria (5th June) were occupied, and the South African Republic and the Orange Free State were proclaimed British colonies. On the collapse of the Boer forces President Kruger fled to Lorenzo Marques and thence to Europe, where he arrived on 22nd November, seeking in vain to secure European intervention. The war afterwards drifted into a series of guerilla raids by small bodies of Boers, the British forces being under the command of Lord Kitchener after Lord Roberts returned home in December to assume the position of Commander-in-chief.
